Mosby's

Paramedic Textbook

ABOUT THE AUTHOR AND CONTRIBUTORS

Mick J. Sanders, EMT-P, MSA, received his paramedic training in 1978 from St. Louis University Hospitals. He earned a Bachelor of Science degree and a Master of Science degree from Lindenwood University in St. Charles, Missouri. He has worked in various health care systems as a field paramedic, emergency department paramedic, and EMS instructor. For 12 years, Mr. Sanders served as Training Specialist with the Bureau of Emergency Medical Services, Missouri Department of Health, where he oversaw EMT and paramedic training and licensure in St. Louis city and the surrounding metropolitan areas.

Kim D. McKenna, MEd, RN, CEN, EMT-P is the Director of Education for the St. Charles County Ambulance District and Adjunct Professor at Lindenwood University, located in the metropolitan St. Louis, Missouri area. There she is primary instructor for the paramedic program, program director for the district's emergency medical technician programs, and leads a training staff that provides education for district paramedics and for firefighters and emergency personnel within St. Charles County. Kim has been teaching in EMS for more than 25 years. She formerly worked as an emergency and intensive care nurse, and served as Chief Medical Officer for the Florissant Valley Fire Protection District for 6 years. Kim was the EMR Project Level Leader for the National EMS Education Standards project and is currently a Board of Director for the National Association of EMS Educators.

Lawrence M. Lewis, MD, FACEP, is Professor of Emergency Medicine in Medicine at Washington University School of Medicine and Barnes-Jewish Hospital in St. Louis, Missouri. He completed his medical school training at the University of Miami School of Medicine before attending a residency at Washington University. Dr. Lewis is an active researcher in emergency medicine with more than 60 publications and serves on several national and state emergency medicine committees.

Gary Quick, MD, FACEP retired as Medical Director at Southwestern Medical Center, Lawton, Oklahoma in December, 2010. Previously he served as an Associate Professor and Chair of the Department of Emergency Medicine at the University of Oklahoma Health Sciences Center in Oklahoma City, Oklahoma. Dr. Quick is a career emergency physician with 40 years in clinical practice, as well as extensive educational and research experience. He is widely published with more than 100 articles and book chapters to his credit. Before his retirement, he served the specialty of emergency medicine in several capacities at the national and state level for the American College of Emergency Physicians..

James H. Sanders

Preface

As a paramedic student, you have chosen to work in an exciting and rewarding area of health care prehospital emergency care. Few professions can provide the same type of opportunities that lie before you. Through your training, you will meet the educational demands of a profession that requires knowledge in anatomy and physiology, mathematics, pharmacology, advanced education in the health sciences, and physical skills in using highly technical and sophisticated equipment. You will have an opportunity to play an important role in injury prevention, to participate in research, and to be a role model in your community. And most importantly, you will be entrusted with the lives of the people you serve. This describes today's paramedic–a member of a unique profession composed of highly trained men and women dedicated to making a difference in people's lives.

CONTENT AND ORGANIZATION

The fourth edition of *Mosby's Paramedic Textbook* has been extensively reviewed by physicians, nurses, paramedics, educators, and national and international experts in the field of emergency care people who know and value the important role of the paramedic in health care delivery. The text was developed from the 2008 National Highway Traffic Safety Administration's National EMS Education Standards Instructional Guidelines for Paramedics. Every effort was made to meet *all* educational components as defined in that document. The fourth edition has also been enhanced to address recent advances and important issues in emergency medical services (EMS), including new equipment and procedures; critical care transport (CCT); and special considerations for dealing with bioterrorism and weapons of mass destruction (WMD).

Part One explains the paramedic's role and the unique aspects of the profession, such as an overview of EMS systems and the importance of personal well-being. It also introduces the paramedic student to medical/legal issues, ethics, documentation, and EMS communications. New chapters included in this section include Injury Prevention and Public Health (Chapter 3) and Research Principles and Evidence-Based Practice (Chapter 8). Personal safety is emphasized in Part One and throughout the text.

Part Two provides a review of human systems and is an easily located reference for anatomical structures and their functions. This section begins with a new chapter to explain Medical Terminology (Chapter 9). The general principles of pathophysiology lay the foundation for the textbook and are presented here as well. Chapters that map lifespan development and special considerations for specific age groups are included in this section.

Part Three introduces the paramedic student to pharmacology, methods of venous access, and medication administration. The pharmacology chapter has been enhanced to include new emergency drugs. It also has an expanded appendix on herbal products, their common uses, indications, and possible interactions with medications.

Part Four is devoted to airway management and ventilation. The physiology of the respiratory system is presented in depth, and basic and advanced methods of managing a patient's airway with new equipment and techniques are illustrated in this chapter.

Part Five focuses on patient assessment and the importance of caring for both the physical and emotional needs of the patient. New chapters devoted to Scene Size-Up (Chapter 16), Primary Assessment (Chapter 19), and Secondary Assessment (Chapter 20) are included in this edition. Separate chapters address therapeutic communications, history taking, and clinical decision making.

Part Six covers cardiology in detail. Electrophysiology of the heart and electrocardiogram (ECG) interpretation is presented first and is followed by cardiovascular emergencies such as cardiac rhythm disturbances, myocardial infarction, and stroke. Techniques in managing cardiac emergencies, including basic and advanced cardiac life support, follow the 2010 guidelines established by the American Red Cross (ARC) and the American Heart Association (AHA).

Part Seven addresses the many types of medical conditions that can lead to an emergency response. New chapters to this edition are Diseases of the Eyes, Ears, Nose, and Throat (Chapter 23), Immunology (Chapter 27), and Nontraumatic Musculoskeletal Disorders (Chapter 33). Separate chapters are included for disorders of specific body systems. Discussed in depth here are respiratory, neurology, endocrinology, gastrointestinal, genitourinary, gynecology, and hematology disorders. In addition, infectious and communicable diseases, toxicology, and behavioral and psychiatric disorders are covered in detail.

Part Eight is a complete discussion of the Pathophysiology and Management of Shock, a complicated disease process that can affect both medical and trauma patients.

Part Nine is devoted to a thorough presentation of trauma. It begins with a discussion of trauma systems and mechanism of injury. This is followed by separate chapters on bleeding and soft tissue trauma; burns; head, face, and neck trauma; and injury to the spine, chest, abdomen, and musculoskeletal system. A separate chapter on Environmental Conditions (Chapter 45) describes illness and injury that can result from exposure to elements in the environment.

Part Ten describes special considerations for select patient groups such as pregnant women, neonates, pediatrics, and geriatrics. It also addresses the needs of patients who have been victims of abuse and neglect, those with special challenges, and home care patients who may require acute interventions.

Part Eleven deals with the various aspects of advanced EMS systems, such as ambulance operations, medical incident command, rescue operations, crime scene awareness, and hazardous materials incidents. A separate chapter that provides an overview of bioterrorism and weapons of mass destruction is included here, reflecting the hazards and responsibilities important to today's paramedic. The last chapter in this section (Chapter 59) "puts it all together" for the student. It serves as a review of the important concepts in providing emergency care that have been presented throughout the text. Finally, a new appendix has been included to provide an overview of advanced practice procedures for the critical care paramedic.

Each chapter of *Mosby's Paramedic Textbook* begins with an introduction and a list of objectives that provide an overview of the material to be presented. This allows the student to review the content and progression of each chapter in an easy-to-follow format. Key terms are included to highlight terminology and concepts critical to providing emergency care, and boldfaced items identify terms that are included in the glossary. Each chapter concludes with current references that can be used as a resource for supplemental reading and a bulleted summary that reviews the most important material presented in the chapter. The textbook also is accompanied by a student workbook to help measure understanding of the core material. Included in the workbook are questions, activities, and case studies designed to enhance understanding, promote reflection on learning, and integrate key concepts and knowledge.

The fourth edition of *Mosby's Paramedic Textbook* also includes the following features that help make this textbook a leader in EMS education:

- Emergency Drug Index. The Emergency Drug Index (EDI) details specific information on more than 70 emergency drugs. It provides a quick source of reference for a drug's description, onset and duration, indications, contraindications, adverse reactions, drug interactions, packaging, dosage and administration for adult and pediatric patients, and special considerations. Drugs in the textbook that are found in the EDI are denoted with a bold italic font as a reminder to the reader of their importance and easy location of reference.
- Critical Thinking Questions. Critical thinking questions are found in each chapter to aid in understanding concepts and how information presented in the text can impact day-to-day activities and "real life" patient care.
- Advanced ECG Rhythm Interpretation. All cardiac rhythms and dysrhythmias are presented in lead I, II, III, and MCL_1 to enhance assessment of the cardiac patient. In addition, the text includes advanced electrophysiology, 12-lead monitoring, fibrinolytic therapy, and current treatment modalities as recommended by the American Heart Association.
- Full-Color Illustrations. More than 1500 tables, charts, line drawings, and photographs are included in the text to illustrate anatomy, physiology, and patient management guidelines. State-of-the-art equipment and step-by-step demonstrations of practical skills also are presented in full color to demonstrate emergency care procedures.
- "Did You Know?" The new "Did You Know?" boxes are included throughout the text to expand on interesting and relevant information, such as unusual facts and figures, "nice-to-know" data, and "need-to-know" material, such as the rights of terminally ill patients and the possible effects of biological terrorism.
- Box Notes. Box notes are presented in each chapter to highlight vital information and words of warning.
- "Look Again." The new "Look Again" feature prevents text information from being repeated in numerous chapters. This feature directs the student to the chapters and page numbers where the material was first presented for easy reference and review.
- "Show Me the Evidence." Each new "Show Me the Evidence" feature summarizes a research study related to the chapter content. This feature familiarizes the paramedic with the research process, its language, and its findings. "Show me the Evidence" will encourage students to look for information throughout their careers to promote evidence-based practice.
- Expanded Glossary. The glossary has been expanded to include definitions on hundreds of medical terms and key terms presented in the textbook chapters.
- Index. The thorough and detailed index makes it easy to find information that was presented in the text.

I hope reading this preface reinforces the decision you made to choose this textbook. Whether you're a paramedic student, practicing paramedic, nurse, physician, administrator, or educator, I think you will find this textbook to be a valuable EMS resource.

Mick J. Sanders

Author Acknowledgments

The fourth edition of *Mosby's Paramedic Textbook* resulted from the combined efforts of many talented and dedicated people. In addition to my physician advisers, Larry Lewis and Gary Quick, and the many experts who reviewed the manuscript, I would like to acknowledge a few others who helped make this textbook possible:

Kim McKenna, my friend, colleague, contributor, and the author of the workbook. She's been my "can't-do-without" partner since the first edition of the text. Her devotion, her contributions, and her handling of the art program in this edition have been invaluable. (Kim, I owe you–big time!)

Laura Bayless, my managing editor. Mary Jo Adams, my developmental editor. Rich Barber, my project manager. Together, their support and daily emails helped remind me that there was light at the end of the tunnel. Kim and I are grateful for their involvement. These are the people who made the book "come to life."

Don McKenna and Rick Brady, who supplied the excellent photography. Ray Kemp who provided many of the scene photos for this edition. The paramedics and paramedic students from St. Charles County Ambulance District and their family members who were models in this edition (especially my nephew, Dusty Sanders). The McKenna family (Don, Becky, Ginny, Grant, Kim, Maggie, and Bill). St. Louis City EMS (especially Monroe Yancie), O'Fallon Fire Protection District, and the many equipment manufacturers who supplied photos and illustrations to accompany the text. And of course, a special thanks to the many others who were instrumental in the success of previous editions. Their contributions remain an important part of this project.

Finally, I want to mention a few special people whose interest in me and whose support of this project was something I could always count on: Dixie Allen (my mother), Randy Sanders (my brother), and Will Denney (a great friend).

Mick J. Sanders

Publisher Acknowledgments

The editors wish to acknowledge and thank the many reviewers of this book, who devoted countless hours to intensive review. Their comments were invaluable in helping to develop and fine tune the revision of this textbook.

Organizations and individuals who took part in this extensive project were:

Mark "Sharky" Alexander, EMTP, ACLS, PALS, DMT
EMT-P, PHTLS-Instructor/ Chamber Operator, USCG Master Captain, TDI Closed Circuit Rebreather Instructor and Mixed Gas Diver, PADI Master Instructor,
St. Charles Ambulance District/ Sharky's Underwater Expedition, LCC
St. Charles, Missouri

David S. Becker, MA, EMT-P, EFO
Sanford-Brown College
St. Louis, Missouri

Kristen D. Borchelt, RN, NREMTP

Preface

Chapter Openers set the stage for learning with **Objectives** and **Key Terms** with definitions.

CHAPTER 10

Review of Human Systems

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Discuss the importance of human anatomy as it relates to the paramedic profession.
2. Describe the anatomical position.
3. Properly interpret anatomical directional terms and body planes.
4. List the structures that compose the axial and appendicular regions of the body.
5. Define the divisions of the abdominal region.
6. List the three major body cavities.
7. Describe the contents of the three major body cavities.
8. Discuss the functions of the following cellular structures: the cytoplasmic membrane, the cytoplasm (and organelles), and the nucleus.
9. Describe the process by which human cells reproduce.
10. Differentiate and describe the following tissue types: epithelial tissue, connective tissue, muscle tissue, and nervous tissue.
11. For each of the 11 major organ systems in the human body, label a diagram of anatomical structures; list the functions of the major anatomical structures; and explain how the organs of the system interrelate to perform the specific functions of that system.
12. For the special senses, label a diagram of the anatomical structures of the special senses; list the functions of the anatomical structures of each sense; and explain how the structures of the senses interrelate to perform their specialized functions.

KEY TERMS

abdominal aorta The portion of the descending aorta that passes from the aortic hiatus of the diaphragm into the abdomen, where it divides into the two common iliac arteries.

acetabulum The large, cup-shaped articular cavity at the juncture of the ilium, the ischium, and the pubis that contains the ball-shaped head of the femur.

action potential A change in membrane potential in an excitable tissue that acts as an electrical signal and is propagated in an all-or-none fashion.

adenosine triphosphate (ATP) A nucleotide composed of adenosine, an organic base, with three phosphate groups

alveoli Minute air sacs in the lungs through which gas exchange takes place between alveolar air and pulmonary capillary blood.

amino acids Organic chemical compounds composed of one or more basic amino groups and one or more acidic carboxyl groups.

antidiuretic hormone (ADH) A hormone produced in the posterior pituitary gland that regulates the balance of water in the body by accelerating the resorption of water.

anus The distal end or outlet of the rectum.

aorta The main and largest artery in the body.

anatomical position The position of standing erect with the feet and palms facing the examiner.

Viral Pneumonia

Influenza A is the most common type of **viral pneumonia** (Box 24-7). It often occurs as epidemics in populations of small groups such as schoolchildren, army recruits, and nursing home residents. The interstitial infection caused by the virus predisposes the patient to secondary bacterial pneumonia.

Bacterial Pneumonia

Until 2000, the pneumococcus bacillus (*Streptococcus pneumoniae*) accounted for 90% of bacterial pneumonias. It affected 1 in 500 people each year. The decline in cases is related to vaccination of infants against the pneumococcus bacteria. The peak incidence is in winter and early spring. A vaccine that is now available is effective against this type of pneumonia in adults.

DID YOU KNOW?

Pneumococcal Polysaccharide Vaccine (PPSV)

Pneumococcal disease is the leading cause of vaccine-preventable disease and death in the United States. The disease can lead to serious infections of the lungs (pneumonia), blood (bacteremia), and brain (meningitis). Pneumococcal pneumonia kills about 1 out of 20 people who contract the disease; bacteremia kills about 1 person in 5; and meningitis kills about 3 people in 10.

Pneumococcal polysaccharide vaccine (PPSV) protects against 23 types of pneumococcal bacteria, including those most likely to cause serious disease. Most healthy adults who are vaccinated develop protection to most or all of these types within 2 to 3 weeks of vaccination. Usually only one dose of PPSV is needed, but under some circumstances a second dose may be given. A second dose (given 5 years after the first dose) is recommended for:

- People 65 years and older who received their first dose when they were younger than 65 and it has been 5 or more years since the first dose
- People 2 through 64 years of age who:
  - Have a damaged spleen or no spleen
  - Have sickle cell disease
  - Have HIV infection or AIDS
  - Have cancer, leukemia, lymphoma, or multiple myeloma
  - Have nephrotic syndrome
  - Have received an organ or bone marrow transplant
  - Are taking medication that lowers immunity such as chemotherapy or long-term steroids

People to whom the vaccine should not be given include those who are allergic to the vaccine or a component of the vaccine; those who are moderately or severely ill; and women who are pregnant. Another type of pneumococcal vaccine, pneumococcal conjugate vaccine, or PCV) is routinely recommended for children younger than 5 years of age.[13]

Bacterial pneumonia also can result from the aspiration of mucus and saliva. Therefore patients in a coma or with seizures, suppressed cough reflex, and increased secretion

BOX 24-7 Influenza

Influenza is an acute, febrile disease that affects the entire body. It is associated with viral infection of the upper and lower respiratory tracts. It usually is characterized by the abrupt onset of a severe protracted cough, fever, headache, muscle ache, and mild sore throat. Of all the viruses, the influenza and parainfluenza viruses are the most common causes of serious respiratory tract infections. Moreover, they have high morbidity and mortality rates.

Influenza viruses A, B, and C (and their many strains) are known for their potential to quickly cause respiratory tract infections after exposure. (It usually occurs within 24 to 48 hours.) The virus is inhaled in respiratory droplets from infected individuals (such as when an infected person sneezes). The droplets penetrate the surface of upper respiratory tract mucosal cells. The virus eventually spreads to the lower respiratory tract, where it causes cell inflammation and destruction of the cilia. Without the cilia, clearing the airways of infected mucus is more difficult. Consequently, a secondary bacterial infection often develops. This may result in pneumonia or acute respiratory failure. (This is particularly the case in patients with chronic lung disease.)

Influenza has the potential for widespread epidemics. High-risk populations. (These include adults and children with chronic cardiorespiratory or metabolic disorders, residents of nursing homes and other institutions, and health care workers.) Current vaccines are effective against some strains of the virus. These vaccines have minimal side effects. If uncomplicated influenza is self-limiting. Acute symptoms last 2 to 7 days. These are followed by a convalescent period of about 2 weeks.

NOTE: The H1N1 outbreak of 2009 affected healthy young people and pregnant women disproportionately, compared with other influenza viruses (see Chapter 28).

are predisposed to developing the disease. Other ing risk factors that may contribute to the development of bacterial pneumonia include the following:

- Infection
  - Upper respiratory tract infection (influenza)
  - Postoperative infection
- Foreign body aspiration
- Alcohol or other drug addiction
- Cardiac failure
- Stroke
- Syncope
- Pulmonary embolism
- Chronic illness
  - Chronic respiratory disease
  - Diabetes mellitus
  - Congestive heart failure
- Prolonged immobilization
- Compromised immune status

Mycoplasmal Pneumoni

Mycoplasmal pneumonia is caused by *Mycoplasma pneumoniae*. It causes tract infection in school-age children.

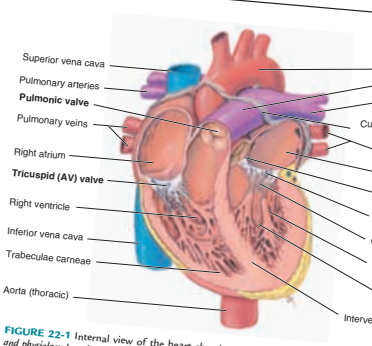

FIGURE 22-1 Internal view of the heart showing the chambers. (Applegate EM: *The anatomy and physiology learning system*, ed 3, St Louis, 2007, Saunders.)

ventricle and pulmonary trunk is the pulmonary semilunar valve. The valve between the left ventricle and the aorta is the aortic semilunar valve. When the ventricles contract, the atrioventricular valves close to prevent blood from flowing back into the atria. When the ventricles relax, semilunar valves close to prevent blood from flowing back into the ventricles.

Blood Supply to the Heart

The coronary arteries are the sole suppliers of arterial blood to the heart. They deliver 200 to 250 mL of blood to the myocardium each minute during rest (Figure 22-2). The left coronary artery carries about 85% of the blood supply to the myocardium. The right coronary artery carries the rest. The coronary arteries begin just above the aortic valve where the aorta exits the heart. These arteries run along the epicardial surface. They divide into smaller vessels as they penetrate the myocardium and the endocardial (inner) surface.

The left main coronary artery supplies the left ventricle, the interventricular septum, and part of the right ventricle. Its two main branches are the left anterior descending artery and the circumflex artery. The right coronary artery supplies the right atrium and ventricle, part of the [illegible] tricle, and the conduction system. Its two main are the right anterior descending branch and t branch. In addition to the blood supply provid arteries, many connections (anastomoses) ex arterioles to provide backup (collateral) circula anastomoses play a key role in providing alterna

of blood flow in the event one or more of the coronary vessels become blocked (Figure 22-3).

CRITICAL THINKING
Why is collateral circulation important?

Coronary capillaries all[illegible]e exchange of nutrients and metabolic wastes. Th[illegible]s merge to form coronary veins. These veins deliv[illegible]most of the blood to the coronary sinus. The coronar[illegible]nus empties directly into the right atrium. The coron[illegible]sinus is the major vein draining the myocardium.

PHYSIOLOGY

The heart can be thought of as[illegible]pumps in one. One is a low-pressure pump (right atriu[illegible]nd right ventricle). This pump supplies blood to the l[illegible]s. The other is a high-pressure pump (left atrium anc[illegible]t ventricle). This pump supplies blood to the body. The r[illegible]e atrium receives blood from the [illegible]

Did You Know? boxes expand on interesting and relevant information, such as unusual facts and figures, "nice-to-know" data, and "need-to-know" material.

Boxed **Critical Thinking** questions aid in understanding concepts and how chapter content impacts patient care.

BUNDLE BRANCH ANATOMY

To review, the bundle of His begins at the atrioventricular node and divides to form the left and right bundle branches (Figure 22-84). The right bundle branch continues toward the apex and spreads throughout the right ventricle. The left bundle branch subdivides into the anterior and posterior fascicles and spreads throughout the left ventricle. Conduction of electrical impulses through the Purkinje fibers stimulates the ventricles to contract.

With normal conduction, the first part of the ventricle to be stimulated is the left side of the septum. The electrical impulse then traverses the septum to stimulate the other side. Shortly thereafter, the left and right ventricles are stimulated at the same time. The left ventricle normally is much larger and thicker than the right ventricle; therefore, its electrical activity predominates over that of the right ventricle.

COMMON ELECTROCARDIOGRAM FINDINGS

When an electrical impulse is blocked from passing through the right or left bundle branch, aberration (abnormal conduction) occurs and one ventricle depolarizes and contracts before the other. Ventricular activation no longer occurs at the same time. As a result, the QRS complex widens (often with a slurred or notched appearance known as *rabbit ears*). The hallmark of bundle branch block is a QRS complex equal to or greater than 0.12 second. The two criteria for recognizing bundle branch block are:

- A QRS complex equal to or greater than 0.12 second
- QRS complexes produced by supraventricular activity

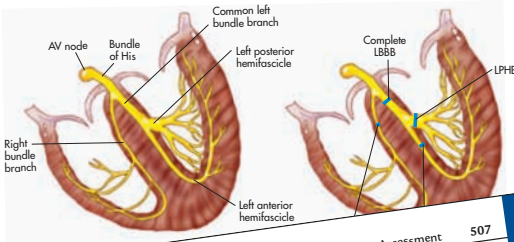
NOTE

Bundle branch block and *hemiblock* (fascicular block) are terms used to describe abnormal conduction or the interruption of impulses from above the bundle branches to the ventricles. The interruption may occur in either the anterior (superior) or the posterior (inferior) division. These patterns of abnormal or aberrant conduction must be recognized as different from beats of ventricular origin. Beats of ventricular origin can have similar QRS complex shapes.

Ventricular conduction disturbances are identified best by monitoring leads V_1 and V_6 with a 12-lead machine. These leads permit the easiest differentiation of the right and left bundle branch blocks. Lead V_1 looks at right and left bundle branches and should be monitored during transport of these patients.[7]

Normal Conduction. In normal ventricular stimulation, the electrical impulse reaches the septum first. It then travels from the left endocardium to the right endocardium of the septum (Figure 22-85). This impulse generates a small R wave in V_1. The rest of the impulses mainly are conducted away from the V_1 electrode. This yields a negative deflection. Therefore, during normal conduction, V_1 mainly is negative. The QRS complex also is usually 0.08 to 0.10 second wide (the same as any other narrow QRS complex).

Right Bundle Branch Block. In **right bundle branch block** (RBBB), the left bundle branch performs normally. Therefore, the left branch activates the left side of the heart before the right (Figure 22-86). When the left ventricle



Patients who *appear stable, but potentially unstable*, are injured or have underlying illness or disease. These patients may be conscious and alert and their vital signs may or may not be within normal limits. Their history of an injury or an underlying illness or disease alerts the paramedic that a decline in their status may occur. These patients are potentially unstable and always require transport for physician evaluation.

Patients who appear *unstable* have obvious signs of serious injury, illness, or disease. Their injury or illness is life threatening. These patients require immediate care and transportation to a medical facility. Initial on-scene care may include **resuscitation.**

Assessment for Life-Threatening Conditions

To assess for life-threatening conditions, the paramedic should conduct a systematic evaluation of the patient's level of consciousness, airway, breathing, and circulation.

LEVEL OF CONSCIOUSNESS

A first priority with any patient is to assess the level of consciousness. This assessment usually can be accomplished with a warm exchange with the patient. An example of such is "Hi. My name is ____. I'm a paramedic. How can I help you?" If the patient does not respond to verbal stimuli, the paramedic should assess if the patient responds to painful stimuli. This should begin with gentle tactile stimulation (e.g., rubbing the patient's shoulder), along with questions such as "Are you okay?" and "Can you hear me?" If there is no response, uncomfortable stimuli should be used to illicit a response. An example of an uncomfortable stimulus is rubbing the patient's sternum (*sternal rub*). A patient who does not respond to verbal or painful stimuli is considered unresponsive. As described in Chapter 15, the airway of any unconscious patient or any patient without a gag reflex or cough reflex must be secured immediately.

CRITICAL THINKING

What does a patient's level of consciousness tell you about the patient's oxygenation and circulation?

SHOW ME THE EVIDENCE

Researchers at an 896-bed hospital evaluated assessment of level of consciousness using the Glasgow Coma Scale (GCS) and the AVPU (awake, responds to verbal stimulation, responds to painful stimulation, unresponsive) responsiveness scale in intentional and accidental poisoning patients who arrived to their hospital over a 6-month period in 2003. Their goal was to evaluate whether the scores could be linked to each other. A total of 1384 patients met their inclusion criteria. Although there was overlap in the scores, their data suggested the following: alert (median GCS 15); responsive to painful stimulation (median GCS 13); responsive to painful stimulation (median GCS 8); and unresponsive (median GCS 3). In general, there was difficulty using both scales in alcohol-intoxicated patients.

Kelly C, Upex Ad, Bateman D: Comparison of consciousness level assessment in the poisoned patient using the alert/verbal/painful/unresponsive scale and the Glasgow coma scale, *Ann Emerg Med* 44(2):108-113, 2004.

AIRWAY STATUS

The paramedic should assess the [illegible] of any patient to ensure it is patent with good a[illegible]nge. If the patient is unresponsive, the airway should be [illegible]ned and cleared of any obstructions (described in Chap[illegible]5).

A responsive patient should be asse[illegible] for the ability to speak, noting signs of airway obstruc[illegible]or, or respiratory insufficiency. These signs could include [illegible]he delivery of gurgling. Any condition that compromis[illegible]atening and oxygen to body tissues is potentially life [illegible]y compromise the airway include the following:

- Tongue obstructing the airway in an uncon[illegible]s patient
- Loose teeth or foreign objects in the patient[illegible]rway
- Epiglottitis
- Upper airway obstruction from any cause
- Facial and oral bleeding
- Vomitus
- Soft tissue trauma to the patient's face and neck
- Facial fractures

A compromised airway must be secured manually (using a modified jaw-thrust or chin-lift maneuver), or with adjunct equipment (e.g., oral or nasal airways, suction apparatus, or an advanced airway device; described in Chapter 15) (Fig. 19-4). When performing an airway procedure for patients who may have a cervical spine injury, the paramedic must keep manipulation of the cervical spine to a minimum and stabilize the head and neck in a neutral position. All patients must have an airway established and maintained during the primary survey.

Figure 19-4 Paramedic opening an airway with head-tilt/chin-lift maneuver.

Purposes.[1] First, the patient history places emphasis on identifying life-threatening conditions that require immediate intervention. That is, it gives full attention to the "needs of the moment." The patient history provides information that leads to appropriate care for the patient who is *urgent* (unstable), *emergent* (potentially unstable), and *nonemergent* (stable). In addition, the patient history identifies the potential for life threats as well as the existence of a current life threat.

Finally, the patient history can be expanded when appropriate to allow opportunities for patient education. It can also allow opportunities to provide service referrals to agencies and organizations that can help the patient and/or family with specific health care needs.

BOX 18-1 Content of the Patient History

Date and Time
Identifying Data
- Age
- Gender
- Race
- Occupation

Source of Referral
- Patient referral
- Referral by others

Source of History
- Patient
- Family
- Friends
- Police
- Others

Reliability
- Variable (memory, trust, motivation)
- Determined at the end of the evaluation

Chief Complaint
- Main part of history
- The one or more symptoms for which the patient is seeking medical care

Present Illness
- Identifies the chief complaint
- Provides a chronological account of the patient's symptoms

Medical History
Current Health Status
Review of Body Systems

CONTENT OF THE PATI[illegible]ISTORY

The patient history is made up of [illegible] parts. Each of these parts has a specific purpose, which c[illegible]s a "snapshot" of patients and their condition. Box 18-1 [illegible]s the parts of a patient history, as described in this chap[illegible]

The patient history should include th[illegible]te and time that the history was obtained. The histo[illegible]also should contain any identifying information of th[illegible]atient (e.g., age, gender, race, and occupation). Identifyi[illegible]formation an be key, as illustrated in the following s[illegible]ario: Your ew has been dispatched to a "sick case." O[illegible]ur arrival u find a woman who is ill with flulike sy[illegible]oms. The ptoms include nausea, vomiting, and diar[illegible]. During r interview, she tells you that she is a 49-ye[illegible]ld busi- woman. She has just returned to the Un[illegible] States an extended visit to her native home in [illegible]utheast n addition to the chance of gastrointestina[illegible]ness or oisoning, you now suspect that she could h[illegible] from rmic disease (that is, a disease prevalent in a[illegible]pula- geographical region).

mentation should include the source of the[illegible]rral nt history. For example, did the patient [illegible]est ance, or did a family member, friend, law e[illegible]ce- r, or bystander initiate the EMS respons[illegible]he lso must decide whether the source of the [illegible]r- ent history is reliable, as illustrated in th[illegible]l- rio: Your crew has been dispatched to a[illegible] ver of the car is a 17-year-old who has m[illegible] slurring his speech. In addition, his br[illegible] lor resemi[illegible] to you a[illegible] patient[illegible] plaint ([illegible] the par[illegible] EMS [illegible] t, the [illegible]

description of the present illness or injury. This history provides a chronological account of the patient's symptoms. The paramedic then questions the patient about any past medical history and current health status. Also, the paramedic performs a review of body systems appropriate to the patient's symptoms or complaint (see Chapter 20).

TECHNIQUES OF HISTORY TAKING

As described in Chapter 17, it is important to "set the stage" for a good paramedic-pa[illegible]

Patient's personal space.

Look Again boxes direct the student to the chapters and page numbers where the material was first presented for easy reference and review.

Note boxes highlight vital information and words of warning.

Show Me The Evidence boxes help familiarize the paramedic with the research process and encourages students to look for information throughout their careers to promote evidence-based practice.

CRITICAL THINKING
A patient has made an EMS call about a cardiovascular complaint. What emotions might the patient be feeling?

Chief Complaint

Cardiovascular disease may cause a variety of symptoms. Obtaining an appropriate history of each symptom is important to form a diagnostic impression of any patient with a possible coronary event. Common chief complaints include chest pain or discomfort, including shoulder, arm, neck, or jaw pain or discomfort; dyspnea; syncope; and abnormal heartbeat or palpitations.

In some patients (e.g., some women, older adults, and patients with diabetes), cardiovascular problems commonly have atypical symptoms. These include mental status changes, abdominal or gastrointestinal symptoms (including persistent heartburn), and vague complaints of feeling ill.

CHEST PAIN OR DISCOMFORT

Chest pain or discomfort is the most common chief complaint of patients with myocardial infarction. However, many causes of chest pain are not related to cardiac disease (e.g., pulmonary embolus, pleurisy, reflux esophagitis). Therefore, a history of chest pain is a key factor. The OPQRST method (or a similar method) should be used to

we are working on it. It helps us as we complete a task. Reflection in action promotes critical thinking and bridges the gap between "knowing and doing."

- **Question assumptions:** Apply critical thinking to continuously look for good ideas and new solutions. This will help to set priorities and to problem solve.
- **Reflection bias ("hindsight" bias):** Avoid the tendency to judge an event, because a bad outcome is known from a previous experience you had. (*"I knew that was going to happen."*) Reflection bias is the inclination to see events that have occurred in the past as more predictable than they really were. Review the events after the fact and you might foresee the outcome as more preventable. Replace hindsight with insight.
- **Use decision aids:** Use evidence-based decision aids and guidelines (e.g., algorithms, pocket guides) to simplify decision making and improve patient safety. Decision aids can also facilitate patients' participation in decisions about their care, when appropriate.
- **Ask for help:** You are functioning as part of a team. Don't be hesitant to ask your crew members or medical direction for help or advice, if the need arises. If you are unsure about a decision, drug dose, or procedure, remember that patient safety comes first.

SUMMARY

- The roots of prehospital emergency care may date back to the military.
- In the early twentieth century through the mid-1960s, prehospital care in the United States was provided in a few ways. Care was provided mostly by urban hospital-based systems. These systems later developed into municipal services. Care also was provided by funeral directors and volunteers who were not trained in these services.
- The operations of an effective EMS system include citizen activation, dispatch, prehospital care, hospital care, and rehabilitation.
- Each level of EMS personnel have their own distinct roles and duties. These roles include telecommunicators (dispatchers), emergency medical responders, EMTs, advanced EMTs, and paramedics. These levels combine to make an effective prehospital EMS system.
- Many professional groups and organizations help to set the standards of EMS. These groups exist at the national, state, regional, and local levels. The groups take part in development, education, and implementation. Being active in such a group helps to promote the status of the paramedic.
- Continuing education is crucial. It provides a way for all health care personnel to maintain basic technical and professional skills.
- Professionalism refers to the way in which a person conducts himself or herself. Professionalism also refers to how one follows the standards of conduct and performance established by the profession.
- The roles and duties of the paramedic can be divided into two categories: *primary* and *additional* duties.
- The two types of medical direction are online (direct) and off-line (indirect). Both are equally important. They help to ensure that the components of quality medical care are in place in an EMS system.
- A CQI program identifies and attempts to resolve problems in areas such as medical direction, financing, training, communication, prehospital management and transportation, interfacility transfer, receiving facility specialty care units, dispatch, public information and education, audit and quality assurance, disaster planning, and mutual aid.
- Patient safety should be a high priority during every Errors that may cause injury or illness often handoffs, communication issues, medication airway issues, lifting or moving patients, and crashes, and immobilization.

AMIODARONE (CORDARONE)

CLASS

Class III antidysrhythmic

DESCRIPTION

Amiodarone is a unique antidysrhythmic agent with multiple mechanisms of action. The drug prolongs the duration of the action potential and the effective refractory period, and when given short-term IV, probably includes noncompetitive beta-adrenergic receptor and calcium channel blocker activity.

ONSET AND DURATION

Onset: Within minutes
Duration: Variable

INDICATIONS (IV USE)

Initial treatment and prophylaxis of frequently recurring ventricular fibrillation and hemodynamically unstable ventricular tachycardia in patients unresponsive to shock delivery, CPR, and vasopressors
Recurrent hemodynamically unstable VT
Treatment of some stable atrial and ventricular dysrhythmias

CONTRAINDICATIONS

Pulmonary congestion
Cardiogenic shock
Second- or third-degree AV block if no pacemaker present
Bradycardia
Sensitivity to amiodarone or iodine

ADVERSE REACTIONS

Hypotension
Headache
Dizziness
Bradycardia
Arrioventricular conduction abnormalities
Flushing
Abnormal salivation
Pain at IV site
Liver function abnormalities
Congestive heart failure
Abnormal thyroid function

DRUG INTERACTIONS

May potentiate bradycardia and hypotension with beta blockers and calcium channel blockers.
May increase risk of atrioventricular block and hypotension with calcium channel blockers.
May increase anticoagulant effects of warfarin.
May decrease metabolism and increase serum levels of phenytoin, procainamide, quinidine, and theophyllines.
Routine use in combination with drugs that prolong the Q-T interval is not recommended.
Y-site incompatibilities with furosemide, heparin, and sodium bicarbonate

HOW SUPPLIED

50 mg/mL vials

DOSAGE AND ADMINISTRATION

Adult:
Pulseless arrest unresponsive to CPR, shock, and vasopressors: 300 mg IV/IO push. If needed, second dose of 150 mg IV/IO push
Life-threatening dysrhythmias: Max cumulative dose: 2.2 g IV/24 hr. May be given as rapid infusion 150 mg IV over first 10 min (15 mg/min) repeated every 10 min as needed. Slow infusion: 360 mg IV over 6 hr (1 mg/min). Maintenance infusion: 540 mg IV over 18 hr (0.5 mg/min)
Pediatric:
Refractory VF, pulseless VT: 5 mg/kg rapid IV/IO bolus; can be repeated to total dose of 15 mg/kg (2.2 g in adolescents) IV per 24 hr; max single dose: 300 mg
Perfusing supraventricular and ventricular dysrhythmias: Loading dose 5 mg/kg IV/IO over 20-60 min (max single dose: 300 mg); can repeat to a max of 15 mg/kg (2.2 g in adolescents) per day IV

SPECIAL CONSIDERATIONS

Pregnancy safety: Category D
Rapid infusion may cause hypotension.
Continuous electrocardiogram monitoring is required.
Slow infusion or discontinue if bradycardia or atrioventricular block occurs.
Do not give with other drugs that prolong Q-T interval (e.g., procainamide).
Maintain at room temperature and protect from excessive heat.

ASPIRIN (ASA, B[illegible]ER, ECOTRIN, ST. JOSEPH, OT[illegible]

CLASS

Analgesic, antiinflammatory, an[illegible]etic, antiplatelet

DESCRIPTION

Aspirin decreases inflammation (analg[illegible]ffect not limited to effects in CNS), dilates peripheral ves[illegible]and decreases platelet aggregation. The use of aspirin is[illegible]ngly recommended for all patients with acute coronary[illegible]drome.

ONSET AND DURATION

Onset: 15-30 min
Duration: 4-6 hr

INDICATIONS

Mild to moderate pain or fever
Prevention of platelet aggregation in ischemia and thromboembolism

Perfect for review, each chapter includes a bulleted **Summary** and a list of **References** (most chapters include suggested readings).

Emergency Drug Index lists 78 commonly prescribed medications that are used in prehospital care.

CCT APPENDIX: ADVANCED PRACTICE PROCEDURES FOR THE CRITICAL CARE PARAMEDIC, 1694

PART ONE

Preparatory

Chapter 1: EMS Systems: Roles, Responsibilities, and Professionalism

Chapter 2: Well-Being of the Paramedic

Chapter 3: Injury Prevention and Public Health

Chapter 4: Documentation

Chapter 5: EMS Communications

Chapter 6: Medical and Legal Issues

Chapter 7: Ethics

Chapter 8: Research Principles and Evidence-Based Practice

CHAPTER

1 EMS Systems: Roles, Responsibilities, and Professionalism

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Outline key historical events that influenced the development of emergency medical services (EMS) systems.
2. Identify the key elements necessary for effective EMS systems operations.
3. Outline the five components of the *EMS Education Agenda for the Future: A Systems Approach*.
4. Describe the benefits of continuing education.
5. Differentiate among the training and roles and responsibilities of the four nationally recognized levels of EMS licensure/certification: Emergency Medical Responder, Emergency Medical Technician, Advanced Emergency Medical Technician, and Paramedic.
6. List the benefits of membership in professional EMS organizations.
7. Differentiate among professionalism, professional licensure, certification, registration, and credentialing.
8. List characteristics of the professional paramedic.
9. Describe the paramedic's role in patient care situations as defined by the U.S. Department of Transportation.
10. Describe the benefits of each component of off-line (indirect) and online (direct) medical direction.
11. Outline the role and components of an effective continuous quality improvement program.
12. Recognize EMS activities that pose a high risk for patients.
13. Describe actions paramedics may take to reduce the chance of errors related to patient care.

KEY TERMS

advanced life support The provision of care that paramedics or allied health professionals render, including advanced airway management, defibrillation, intravenous therapy, and medication administration.

basic life support Care provided by persons trained in first aid, cardiopulmonary resuscitation, and other noninvasive care.

certification A process by which authority is granted to a person to take part in an activity. This person has to meet certain qualifications.

code of ethics A set of guidelines that are designed to set out acceptable behaviors for members of a particular group, association, or profession.

continuous quality improvement A management approach to customer service and organizational performance that includes constant monitoring, evaluation, decisions, and actions.

credentialing A local process that allows a paramedic to practice in a specific EMS agency (or setting).

emergency medical services A national network of services coordinated to provide aid and medical assistance from primary response to definitive care; the network involves personnel trained in rescue, stabilization, transportation, and advanced management of traumatic and medical emergencies.

extended scope of practice The expansion of health care services provided by emergency medical services personnel in the prehospital setting.

licensure A process of regulating occupations through licenses granted by a government authority.

managed care organizations Networks that provide patient care services to their members, including health maintenance organizations and preferred provider organizations.

medical oversight The ultimate responsibility and authority for the medical actions of an EMS system; usually provided by one or more physicians.

off-line (indirect) medical direction The establishment and oversight of all medical components of an EMS system, including protocols, standing orders, educational programs, and the quality and delivery of online (direct) medical direction.

online (direct) medical direction The medical direction physician or designee who directly supervises prehospital

care activities via radio or phone. Online (direct) medical direction also may be responsible for the activities of the emergency department staff and others at the medical direction hospital.

paramedic A person who has completed training consistent with the National EMS Education Standards, including advanced training in clinical decision making, patient assessment, cardiac rhythm interpretation, defibrillation, drug therapy, and airway management.

patient care report A document used in the prehospital setting to record all patient care activities and circumstances related to an emergency response.

peritracheal Situated or occurring in the tissues surrounding the trachea.

registration The act of enrolling one's name in a register, or book of record.

reciprocity The practice of granting an individual licensure or certification/registration based on licensure or certification/registration by another state, agency, or association.

standing orders Specific treatment protocols used by prehospital emergency care personnel in the absence of online (direct) medical direction.

treatment protocols Guidelines that define the scope of prehospital intervention practiced by emergency services personnel.

*The role of the paramedic is different than that of the "ambulance driver" of the past. Today's paramedics work in sophisticated **emergency medical services** (EMS) systems. They take part in an array of professional activities. These activities enhance the paramedic's ability to provide quality service and state-of-the-art patient care in the field and in less traditional health care settings.*

EMERGENCY MEDICAL SERVICES SYSTEM DEVELOPMENT

Assigning a time and place to the birth of organized prehospital emergency care is difficult. To understand EMS system development, one must first consider certain events from ancient times to the present.

Before the Twentieth Century

The ancient Egyptians used herbs and drugs as medicine. They also splinted fractured bones, and they performed some surgeries. The Edwin Smith papyrus (circa the seventeenth century BC) depicted medical practice in Egypt. This system referred to the pulsation of the heart, palpation, and abnormal motor functions associated with brain injury. Other ancient texts show that surgery was practiced by the Babylonians of Mesopotamia, an ancient region of southwest Asia, as early as 1700 BC.[1]

Organized prehospital emergency care has its roots in military history. Paintings of Roman battlefields suggest that some of the warriors cared for the injured. The first "ambulance" is thought to have been a covered cart used by one of Napoleon's surgeons, Dominique-Jean Larrey. He moved injured soldiers to treatment areas during the Napoleonic wars in the 1800s.[1] The first civilian ambulance services were established in Cincinnati and New York City in the 1860s. In the United States Civil War, there was scandal when Walt Whitman and Matthew Brady reported that 3000 wounded soldiers lay in the field for 3 days and 600 for a week during the 1862 Battle of Bull Run. In response, Surgeon General Jonathan Letterman created an ambulance service for each army corps. They evacuated 10,000 wounded soldiers within 24 hours at the Battle of Antietam in 1863.[2]

DID YOU KNOW?

Clara Barton was an American nurse who served as a frontline volunteer during the American Civil War. She saw first-hand the value of the Red Cross during the Franco-Prussian War of 1870. These experiences encouraged her to establish a society in the United States. Under her leadership, the American Red Cross became the premier disaster relief organization in the world. Clara Barton was the founder and first president of the American Red Cross, which was established on May 21, 1881, in Washington, D.C.[3]

Twentieth Century

During World War I, medical care made rapid progress. Wounded soldiers needed urgent care for their injuries, which often were caused by machine guns and bombs. Thus

the military developed battlefield ambulance corps. During World War II, the military moved wounded soldiers by airplane. Then during the Korean conflict, the military evacuated soldiers with helicopters. During the Vietnam conflict, the military improved urgent care and rapid evacuation with well-trained corpsmen. These efforts became the basis of the prehospital care of the injured today.

From the early twentieth century through the mid-1960s, prehospital care in the United States was provided in several ways. Care mostly was delivered by urban, hospital-based systems. These systems later developed into municipal services. Care also was provided by funeral directors and volunteers who had little or no training in emergency care. Most patients received minimal stabilization at the scene. Then they were transported quickly to the nearest hospital.

CRITICAL THINKING

How would you feel about moving to an area with this minimal level of emergency medical services?

Two landmarks in EMS development occurred in 1966:

1. The National Academy of Sciences–National Research Council Committee on Trauma and Shock published *Accidental Death and Disability: The Neglected Disease of Modern Society* (the "white paper"). This document lists recommendations to improve care for victims. Eleven of these recommendations are related directly to EMS (Box 1-1).
2. The U.S. Congress passed the Highway Safety Act of 1966. This act created the U.S. Department of Transportation. Congress also created the National Highway Traffic Safety Administration (NHTSA). The act provided legislative authority and funds to improve EMS and directed states to develop effective EMS programs. If the states did not develop effective EMS programs, they were subject to a loss of up to 10% of their federal highway construction funds. As a result of this act, states gave more than $142 million between 1968 and 1979 to develop EMS and early **advanced life support** (ALS) pilot programs.

Emergency medical services also emerged as a nationwide system because of death rate comparisons from World War I to Vietnam. Death rates for battlefield casualties were 8% in World War I. In World War II, they were 4.5%. In Korea, they decreased to 2.5%. Then in Vietnam, they were less than 2%. This decline was due to advances in field care for trauma patients (Box 1-2).[4] These and other factors helped formulate the blueprint for improving prehospital emergency medical care in the United States. During 1972 and 1973, federal and private sources provided $31 million to fund EMS programs in 37 states and Puerto Rico.

In 1973, Congress passed the Emergency Medical Service Systems (EMSS) Act. This act paved the way for states to benefit from federal funds. The states could obtain the funds by forming regional EMS agencies. The act listed 15 vital parts of the EMS system (Box 1-3). Plus, the act required emergency care programs funded by the U.S. Department of Health and Human Services to plan and put into practice a regional approach for emergency response and immediate care for trauma patients. This act played a major role in creating regional EMS systems from 1974 to 1981.

BOX 1-1 Eleven Recommendations for Emergency Medical Services Identified in the White Paper

1. Extension of basic and advanced first aid training to greater numbers of the lay public
2. Preparation of nationally acceptable texts, training aids, and courses of instruction for rescue squad personnel, police officers, firefighters, and ambulance attendants
3. Implementation of recent traffic safety legislation to ensure completely adequate standards for ambulance design and construction, ambulance equipment and supplies, and the qualifications and supervision of ambulance personnel
4. Adoption at the state level of general policies and regulations pertaining to ambulance services
5. Adoption at district, county, and municipal levels of ways and means of providing ambulance services applicable to the conditions of the locality, control and surveillance of ambulance services, and coordination of ambulance services with health departments, hospitals, traffic authorities, and communication services
6. Initiation of pilot programs to determine the efficacy of providing physician-staffed ambulances for care at the site of injury and during transportation
7. Initiation of pilot programs to evaluate automotive and helicopter ambulance services in sparsely populated areas and in regions where many communities lack hospital facilities adequate to care for seriously injured persons
8. Delineation of radio frequency channels and equipment suitable to provide voice communication between ambulances, emergency departments, and other health-related agencies at the community, regional, and national levels
9. Initiation of pilot studies across the nation for evaluation of models of radio and telephone installations to ensure effectiveness of communication facilities
10. Day-to-day use of voice communication facilities by the agencies serving emergency medical needs
11. Active exploration of the feasibility of designating a single nationwide telephone number to summon an ambulance

From National Academy of Sciences, National Research Council: *Accidental death and disability: the neglected disease of modern society*, Washington, DC, 1996, National Academy Press.

CRITICAL THINKING

How does the "age" of the emergency medical services profession compare with the "age" of your parents' or grandparents' professions?

BOX 1-2 Medical Advances Made During Wartime

Civil War
- Railroads were used to evacuate casualties
- Army still used ambulances much like Napoleon's
- Death rate was very high because germs were unknown as the cause of infection; barns were used as hospitals
- U.S. Army set up the Medical Corps
- System-wide approach with ambulances on the battlefield transporting wounded to hospitals
  Aid stations
  Field hospitals
  Rear general hospitals
  This model was used until the Vietnam War

World War I
- Poor planning (no field hospitals) caused excessive evacuation times of 12-18 hours
- High mortality rates >20%
- Most died of hemorrhagic shock
- No antibiotics; sepsis was common
- Blood transfusions were just beginning to be used
- Thomas half-ring femur splint was considered the greatest advancement in trauma care at this time

World War II
- Evacuation time for wounded decreased to 4-6 hours
- Antibiotics were developed
- Plasma and blood transfusions became common
- Hospitals were located closer to the front to decrease time to surgery
- Fixed wing air transport began

Korean War
- Evacuation time averaged 2-4 hours
- Helicopter evacuation of wounded was introduced
- More use of electrolyte solutions
- Better antibiotics
- Surgical hospitals located closer to front lines

Vietnam War
- Casualties were taken directly from front lines to surgical hospitals by helicopter
- Average evacuation time was 35 minutes
- Average time to surgery was 1-2 hours
- Civilian systems have never matched these timeframes

Iraq War
- Tourniquets were reintroduced
- Hemostatic agents were developed
- Concept of CAB (circulation-airway-breathing) was developed for patients with exsanguinating hemorrhage[5]

BOX 1-3 Fifteen Required Components of the Emergency Medical Services System

1. Manpower
2. Training
3. Communications
4. Transportation
5. Facilities
6. Critical care units
7. Public safety agencies
8. Consumers
9. Access to care
10. Transfer of patients
11. Medical record keeping
12. Consumer information and education
13. Review and evaluation
14. Disaster linkage
15. Mutual aid

BOX 1-4 The 10 System Elements of the National Highway Traffic Safety Administration

1. Comprehensive emergency medical services and trauma system legislation
2. Resource management and administration
3. Professional training
4. A communication system (9-1-1, communication centers, equipment, and the ability to communicate among ambulances, hospitals, fire departments, and police)
5. A transportation system (air, ground, and water)
6. Facilities (hospitals, trauma centers, specialty centers)
7. An inclusive trauma system fully integrated with emergency medical systems
8. Physician involvement (medical oversight)
9. Public information, education, and prevention
10. Data collection, quality improvement and evaluation, and research.

From National Highway Traffic Safety Administration: *Emergency medical services: NHTSA leading the way*, Washington, DC, 1995, The Administration.

In 1981, funding for EMS development changed due to the Consolidated Omnibus Budget Reconciliation Act (COBRA). This act consolidated EMS funding into state preventive health services block grants. As a result, funding under the EMSS Act was eliminated. These block grants were paid to state health departments instead of regional EMS organizations. Because these grants could be spent on projects other than EMS, the grants fell victim to politics. Thus direct funding for EMS declined. Through cuts in funding and staff, the ability of NHTSA to support the U.S. Department of Health and Human Services effort diminished. As a result, each state had to develop and fund their EMS systems. Thus the great growth that EMS experienced in the 1960s and 1970s declined. NHTSA continues to assist EMS development.[6] In 1988 NHTSA established "10 System Elements" (the Statewide EMS Technical Assistance Program) as a recommended standard for EMS systems (Box 1-4).

In 1996 NHTSA and the Health Resources and Services Administration (HRSA) published a consensus paper that was held in high regard. This document, the *Emergency Medical Services Agenda for the Future*, was referred to as the *Agenda*. The *Agenda* was federally funded and completed by the National Association of EMS Physicians and the National Association of State EMS Directors. These organizations designed the *Agenda* to be used by government and private organizations at the national, state, and local levels. The intent of the document was to build a common vision for the future of EMS. The *Agenda* also was meant to help guide planning, decision making, and policy regarding EMS.

The *Agenda* made 14 suggestions for EMS focused on principles of public health and safety systems (Figure 1-1), including the EMS education system (described later in this chapter). The 14 attributes for EMS identified by the *Agenda* are the following:

1. Integration of health services
2. EMS research
3. Legislation and regulation
4. System finance
5. Human resources
6. Medical direction
7. Education systems
8. Public education
9. Prevention
10. Public access
11. Communication systems
12. Clinical care
13. Information systems
14. Evaluation

Box 1-5 outlines other landmarks in EMS development.

Changes in federal health care reform affect the way health care, including emergency care, is provided. Managed care and **extended scope of practice** are most relevant to EMS. *Managed care* refers to patient care services that are provided to members by **managed care organizations** (e.g., health maintenance organizations [HMOs], preferred provider organizations [PPOs], and other provider networks). These plans now cover about 60% of the U.S. population.[7] This reform affects EMS systems in the way that they provide patient care choices for their clients (e.g., emergency versus nonemergency response, resources, and personnel; transportation modes; and health care facility options).

Extended scope of practice came out of the cost-containment setting of managed care. As it relates to EMS, extended

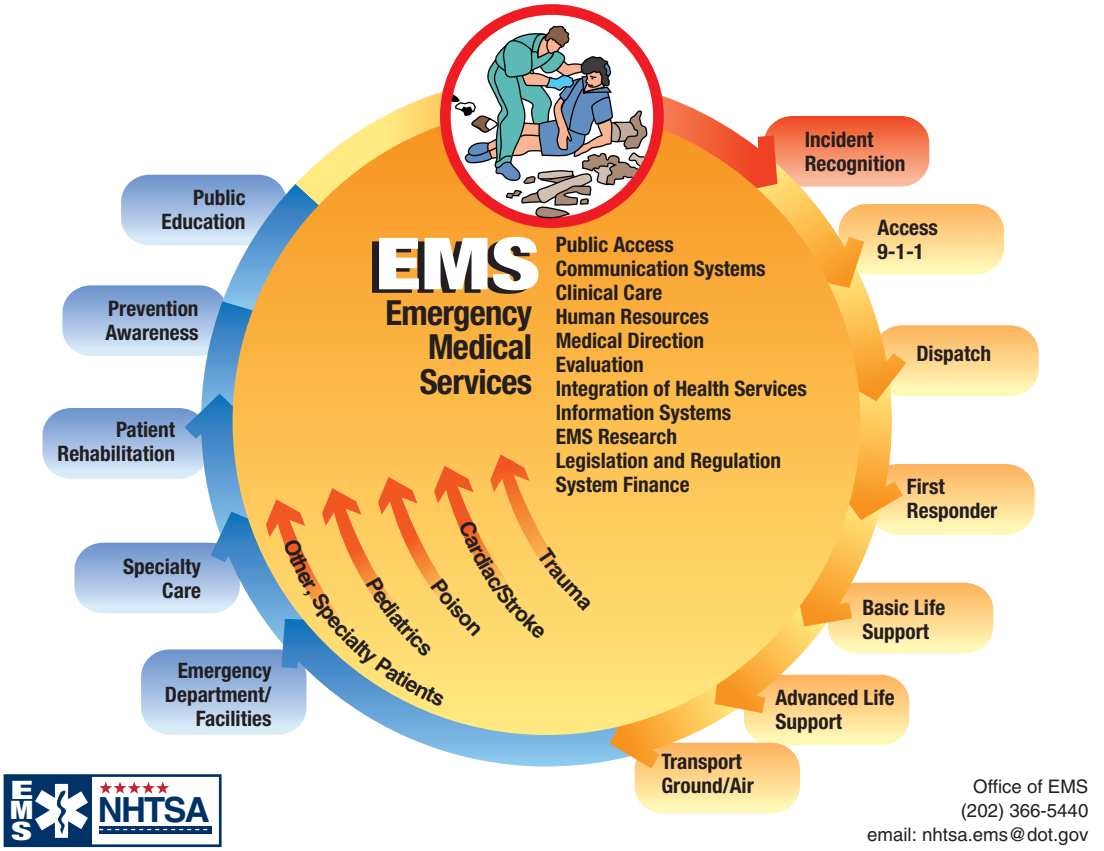

FIGURE 1-1 Emergency medical services: part of the health care system.

BOX 1-5 Other Landmarks in the Development of Emergency Medical Services

- Mid 1950s: The American College of Surgeons develops the first training programs for ambulance attendants.
- 1958: Dr. Peter Safar demonstrates the efficacy of mouth-to-mouth ventilation.
- 1960: Cardiopulmonary resuscitation is shown to be effective.
- 1967: Dr. Eugene Nagel trains Miami firefighters as paramedics at the University of Miami School of Medicine.
- 1968: The American Telephone and Telegraph Company designates 9-1-1 as the universal emergency telephone number.
- 1969: The U.S. Department of Transportation and National Highway Traffic Safety Administration (NHTSA) develop the basic training course for emergency medical technicians (EMTs).
- 1969: The Committee on Ambulance Design develops Ambulance Design Criteria, a report to the U.S. Department of Transportation and the NHTSA to complement the National Academy of Sciences–National Research Council Medical Requirements for Ambulance Design and Equipment (1968). This document recommends ambulance design standards and emergency equipment. The NHTSA agrees to issue matching federal funds to states that purchase vehicles meeting these standards.
- 1970: The National Registry of Emergency Medical Technicians is organized to standardize education, examinations, and certification of EMTs on a national level.
- 1972: President Nixon directs the U.S. Department of Health, Education, and Welfare to develop new ways to organize emergency medical services (EMS), which results in $8.5 million in contracts being awarded to develop a model EMS system.
- 1972: The University of Cincinnati establishes the first residency program to train new physicians exclusively for the practice of emergency medicine.
- 1973: The star of life is adopted as the official symbol for EMS. The six blue bars of the star of life represent the six system functions of EMS: detection, reporting, response, on-scene care, care in transit, and transfer to definitive care.
- 1974: President Gerald Ford proclaims the first National EMS Week.
- 1975: The National Association of Emergency Medical Technicians is founded.
- 1975: The American Medical Association accepts and approves the Paramedic role as an emergency health occupation.
- 1977: More than 40 EMT training agencies throughout the United States develop and test the national training standards for the paramedic for 2 years.
- 1980: The U.S. Department of Health and Human Services releases the *Position Paper on Trauma Center Designation*, which describes trauma centers within EMS systems. The paper also categorizes facilities.
- 1984: The EMS for Children program, under the Public Health Act, provides funding for enhancing the EMS system to better serve pediatric patients.
- 1986: The 1979 Public Safety Officer's Act (SB 1479) is amended to expand the $50,000 compensation to include survivors of rescue squads, ambulance crew members, and public safety department volunteers killed in the line of duty (amended in 1990).
- 1990: President George Bush signs the Trauma Care Systems Planning and Development Act (HR 1602), which provides for annual grants to states based on geographic and population size to help establish and improve trauma systems. In 1995 Congress does not reauthorize funding for this act.
- 1991: Occupational Exposure to Blood-Borne Pathogens; Final Rule (CFR 29 1910. 1030) establishes standards for workplace protection from blood-borne diseases.
- 1993: The Institute of Medicine publishes *Emergency Medical Services for Children*, which points out deficiencies in the ability of the health care system to address the emergency medical needs of pediatric patients.
- 1993: National Registry of EMTs publishes the *National EMS Education and Practice Blueprint.*
- 1995: Congress does not reauthorize funding under the Trauma Care Systems and Development Act.
- 1996: NHTSA and HRSA publish *EMS Agenda for the Future.*
- 1997: The NHTSA publishes *A Leadership Guide to Quality Improvement for Emergency Medical Services Systems*.
- 1998: The U.S. Department of Transportation revises the national standard curriculum for paramedics.
- 2000: *EMS Education Agenda for the Future* is published by NHTSA and HRSA.
- 2004: National Rural Health Association publishes *Rural and Frontier EMS Agenda for the Future*.
- 2005: NHTSA funds National EMS Core Content: The Domain of EMS Practice.
- 2007: *The National EMS Scope of Practice Model* published by NHTSA.

scope of practice refers to expanding services of EMS personnel in the prehospital setting. Examples include providing health screenings, physical examinations, and immunizations. Expanded scope for paramedics will continue to evolve. EMS agencies and managed care programs will develop other useful patient services to enhance revenues, to further injury prevention programs, and to reflect changes in how medical care is delivered. Expanded scope also helps ensure that EMS remains a vital part of the health care system.[8]

NOTE

Medicare and Medicaid are the two insurance programs of the U.S. government. Together, these insurance programs cover about 25% of the U.S. population.[7] These plans have rules that affect how patients qualify for emergency medical services transportation. The rules also decide the conditions under which reimbursement for transportation will occur. This reimbursement became standardized throughout the country in 2002. Standardization occurred through a consensus process involving national emergency medical services agencies and the Center for Medicare Services. The new Medicare fee structure caused major reductions in payment for some emergency medical services agencies but increased fees for others.

CURRENT MEDICAL SERVICES SYSTEMS

The EMS system of today is a network of coordinated services that provides medical care to the community. The coordination is defined by the NHTSA Technical Assistance Program Standards. This coordination ensures that patients are treated quickly and properly and that resources are used efficiently. Together these factors reduce health care costs (Figure 1-2). They also improve patient outcome and reduce hospital stays.[9]

State EMS systems usually are made up of local and regional agencies that manage the delivery of prehospital care. The local agencies are responsible for providing day-to-day EMS to the community. Local agencies also work with regional and state agencies to create protocols and help set standards and guidelines. Local agencies provide data collection services and coordinate mutual aid and disaster planning. Most state EMS agencies have advisory councils to help organize EMS programs and activities. These councils are made up of medical professionals, paraprofessionals, consumers, and public and private agencies with an interest in EMS. The state agency is responsible for licensing and/or certification. In addition, the state enforces state EMS regulations and develops public education programs. Moreover, the state agency acts as a liaison with national agencies. Some of these national agencies include NHTSA, the Federal Emergency Management Agency (FEMA), Homeland Security, and the Maternal Child Health Bureau of the Health Resources and Services Administration.

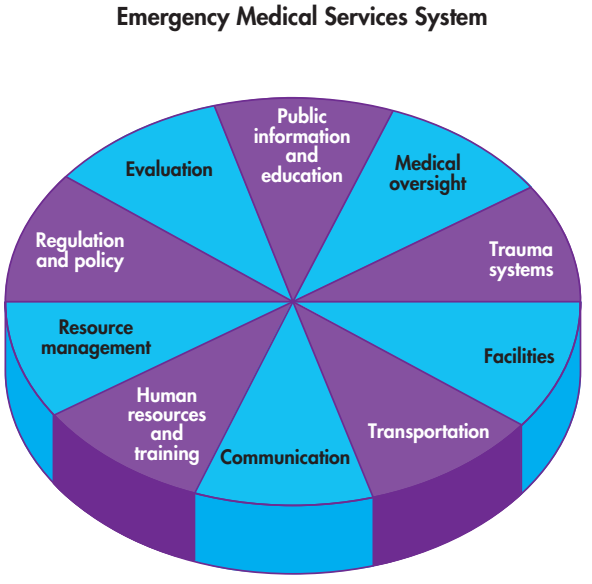

FIGURE 1-2 Ten components of the emergency medical services system. (National Highway Traffic Safety Administration, U.S. Department of Transportation: Emergency medical services: *NHTSA leading the way,* Washington, DC, 1995, The Administration; accessed at www.nhtsa.dot.gov/people/injury/ems/agenda/emsman.html#Services. Accessed April 13, 2011.)

DID YOU KNOW?

NEMSIS stands for the National Emergency Medical Services Information System. NEMSIS is the national repository that will be used to store EMS data from every state in the nation. Since the 1970s, the need for EMS information systems and databases has been well established, and many statewide data systems have been created. However, these EMS systems vary in their ability to collect patient and systems data and allow analysis at a local, state, and national level. For this reason, the NEMSIS project was developed to help states collect more standardized elements and eventually submit the data to a national EMS database. Such a database will be useful in:

- Developing nationwide EMS training curricula
- Evaluating patient and EMS system outcomes
- Facilitating research efforts
- Determining national fee schedules and reimbursement rates
- Addressing resources for disaster and domestic preparedness
- Providing valuable information on other issues or areas of need related to EMS care

Emergency Medical Services System Operations

The operations of an effective EMS system include citizen activation, dispatch, prehospital care, hospital care, and rehabilitation.

CITIZEN ACTIVATION

Emergency public safety services are highly visible in the community. However, the public is not always aware of the complex nature of these services. Citizens expect to have police and fire protection. They also expect to get a quick response with skilled personnel in a medical emergency. These expectations are due to years of available public safety service, public relations, press coverage, and national media. The public also expects such service because of public support in the form of taxes, donations, subscriptions for service, and user fees.

DID YOU KNOW?

In December 1971, the television show "Emergency!" made its debut to millions of viewers. The series starred Randolph Mantooth as paramedic John Gage and Kevin Tighe as his partner, paramedic Roy DeSoto. This popular TV series contributed to a change in public attitudes about fire service and prehospital emergency care. It was also during this time that many fire departments expanded their services to include EMS response.

Public involvement in EMS goes beyond funding. Citizens are often at the scene of an injury or illness. They play an important role in recognizing the need for emergency services. Citizens sometimes administer first aid, help secure the scene and gain access to the patient, and can be instrumental in managing a crisis. Educating the public is

fundamental to the development of an effective EMS system. Paramedics help prepare the public to respond to a medical emergency. They also build support for EMS by helping to develop and present public health care education and prevention programs (see Chapter 3).

CRITICAL THINKING

How is the emergency medical services system funded in your community?

Once citizens recognize that an emergency exists and a call for help is made, the response is coordinated. Citizens usually contact communication centers and dispatching services by emergency phone numbers. The number 9-1-1 offers access to public safety services in most of the country. These services include fire service, law enforcement, and EMS. The availability of emergency access through 9-1-1 continues to expand across the country as areas adopt the system. In areas that do not have 9-1-1, citizens should have easy access to other emergency phone numbers. These numbers can be promoted through public awareness programs, phone stickers, and phone book covers. Other ways of engaging an emergency response include firebox pull stations, citizen band radios, voice over Internet protocol (VOIP), and cell phones. Chapter 5 covers 9-1-1 in more detail.

PREHOSPITAL CARE

Ill or injured patients may need prehospital intervention and stabilization. Interventions may involve **basic life support** (BLS) and ALS skills. Depending on the situation (e.g., entrapment, distance to the hospital, and availability of ALS), initial prehospital care may be limited. The care may consist of giving only comfort and reassurance. Care also may require spinal immobilization, airway protection, endotracheal intubation, intravenous therapy, medication administration, defibrillation, and external cardiac pacing.

HOSPITAL CARE

When the patient is brought to the emergency department, patient care resources expand. This care may include physicians, physician assistants, nurse practitioners, nurses, technicians, ancillary support staff (allied health counselors, social workers, and others), secretaries, and medical record staff. Diagnostic tests are often performed. These services may be provided by laboratory, radiology, and cardiopulmonary departments. Resources available beyond the emergency department include surgery, cardiac catheterization, intensive care, physical therapy, pharmacy, nutrition services, and many others.

REHABILITATION

After hospital delivery and definitive care, many patients receive some type of rehabilitation services. Rehabilitation often occurs before and after hospital discharge. The services may be in the form of education and physical and occupational therapy that help the patient to recover. Rehabilitation also can help the patient to maintain maximal independence. One example of such therapy is helping patients and families adjust to required changes in lifestyle after a myocardial infarction. Another example is retraining in activities of daily living (e.g., bathing and preparing meals). Job rehabilitation also allows patients to adapt to limb impairment or loss.

EMS EDUCATION

The national standard curriculum for paramedics was last revised in 1998. That same year, EMS leaders worked with NHTSA to revise a portion of the *Agenda* (the *National Emergency Medical Services Education and Practice Blueprint* [the *Blueprint*]). This revision revealed the future of EMS education. The text was titled the *EMS Education Agenda for the Future: A Systems Approach* (the *Education Agenda*). The *Education Agenda* named core content categories for each license level. The *Education Agenda* also stressed the integration of EMS within the overall health care system. Figure 1-3 is a diagram of a model that came from the revision.[10] New to this revision was the definition of cognitive (knowledge), psychomotor (skills), and affective (attitude) objectives.

The NHTSA and HRSA also funded the *National EMS Core Content*, which was published in 2005. This document defined the entire domain of out-of-hospital practice. It also identified the universal body of knowledge and skills for EMS personnel. This project was led by the National Association of EMS Physicians and the American College of Emergency Physicians.

The *National EMS Scope of Practice Model* (*Scope of Practice*) was published in 2007. This consensus document defined the four levels of EMS personnel described in this chapter. It also defined the practices and minimum skills for each level. Each educational level assumes mastery of previous competencies for each license level. Each individual must demonstrate each skill within his or her scope of practice and for patients of all ages.

Development of the *National EMS Education Standards* (the *Standards*) was led by the National Association of EMS Educators (NAEMSE). The *Standards* replace NHTSA's national standard curricula that had been the cornerstone of EMS education since the 1960s. The *Standards* define the competencies, clinical behaviors, and judgments that must be met by entry-level EMS personnel at each licensure level. The goal was to meet practice guidelines as defined by the *National EMS Scope of Practice Model*. Content and concepts defined by the *National EMS Core Content* were also integrated within the *Standards*.[11] Box 1-6, EMS History, outlines the timeline of these publications and standards.

NOTE

Each EMS licensure level represents a *significant* difference in skills, risk, knowledge, level of supervision and autonomy, judgment, and clinical decision making.

PARAMEDIC: NATIONAL STANDARDS CURRICULUM
DIAGRAM OF EDUCATIONAL MODEL

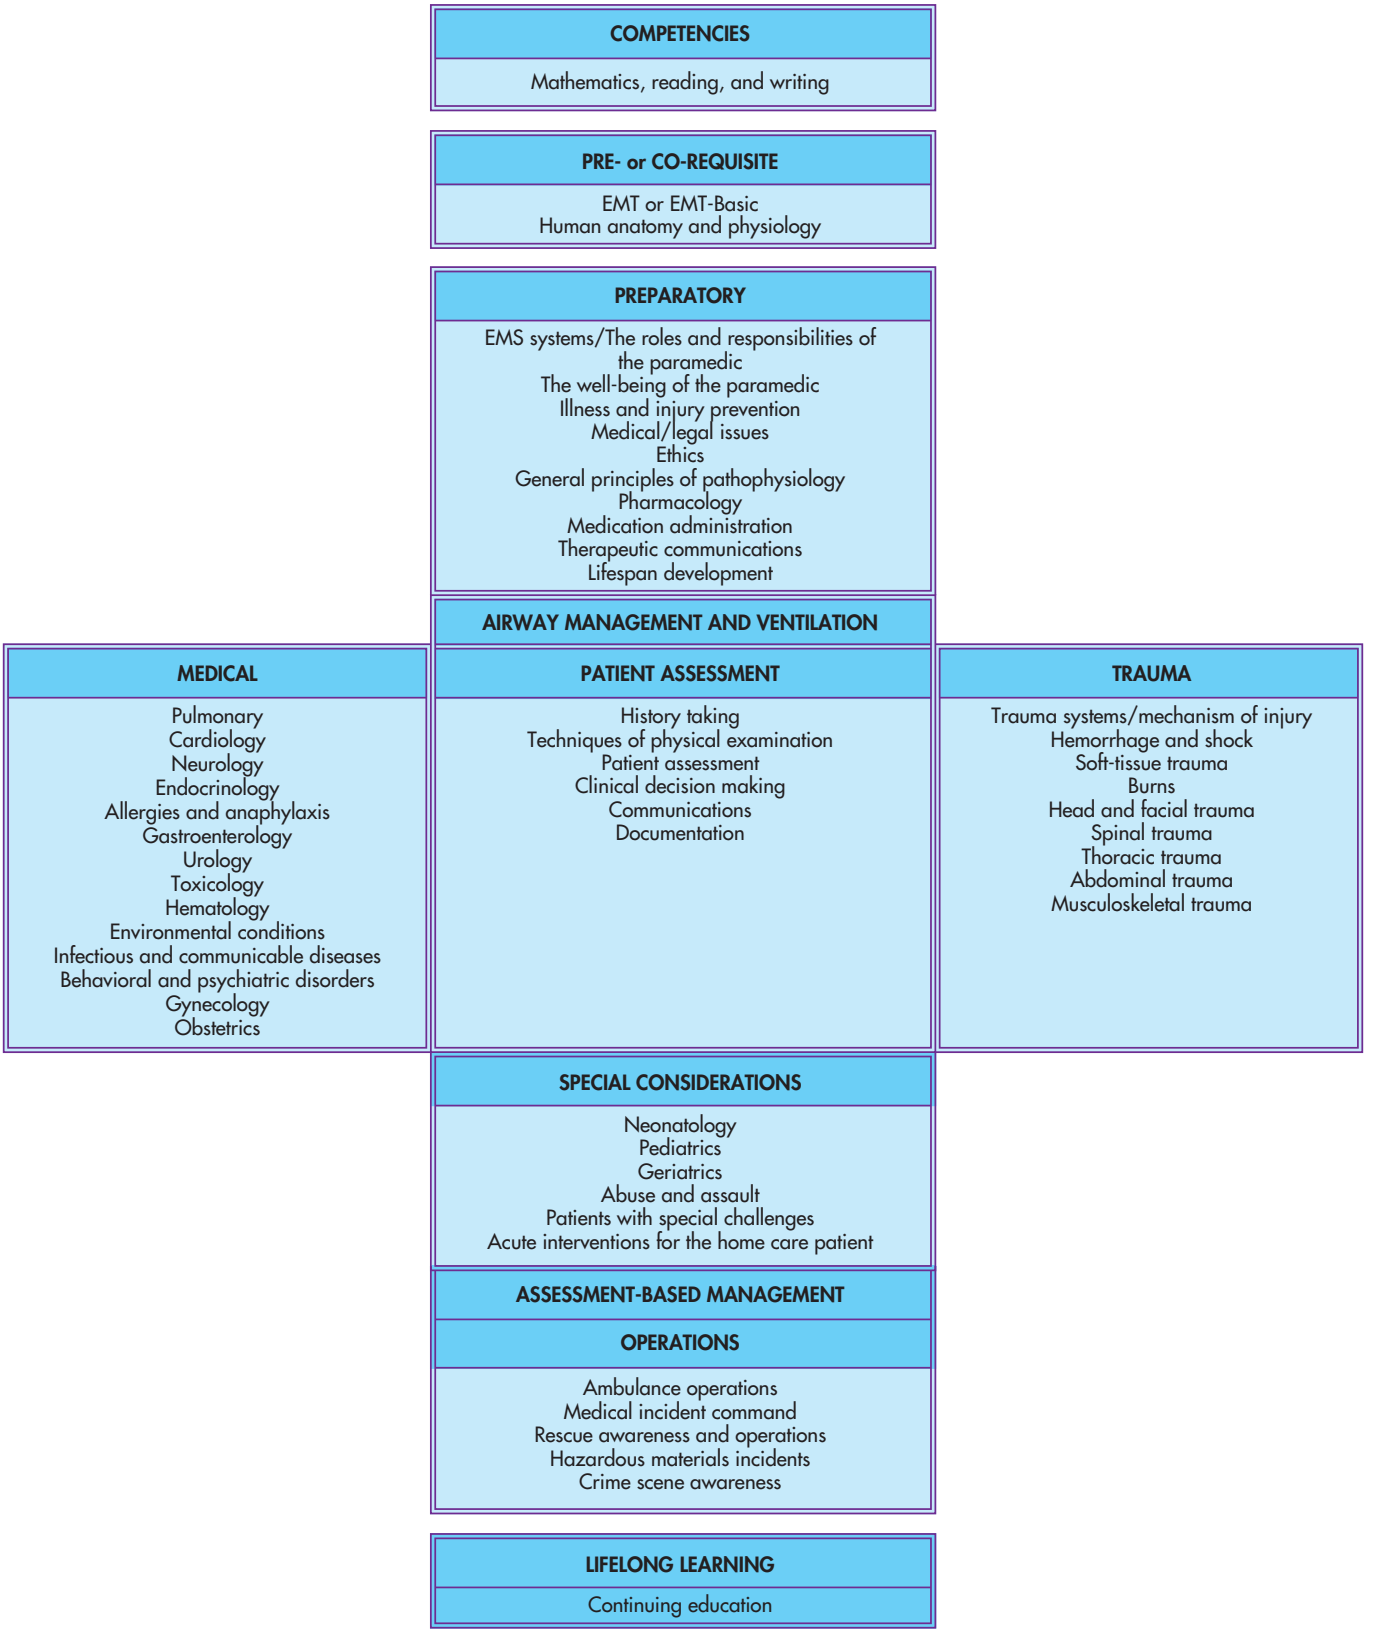

FIGURE 1-3 Diagram of Department of Transportation education model. (U.S. Department of Health and Human Services, Health Resources and Services, Health Resources and Services Administration, Maternal and Child Health Bureau: *Emergency medical services agenda for the future,* Washington, DC, 1999, The Administration.)

NOTE

The *Education Agenda* recommends that EMS students graduate from a nationally accredited EMS educational program to be eligible for National EMS Certification (Figure 1-4). This is to ensure consistency and quality of EMS personnel. National certification is the element critical to extend **reciprocity** to EMS personnel educated in other states. In the future, EMS educational programs will likely require review by the Committee on Accreditation of Educational Programs for Emergency Medical Services Professions (CoAEMSP). The goal of this accreditation is to ensure quality of education and to ensure that appropriate educational infrastructures and resources are available for students in EMS programs. For more information, see The Commission's website at www.caahep.org.

The Five Components of the EMS Agenda: http://www.nhtsa.dot.gov/people/injury/ems/EdAgenda/final/agenda6-00.htm, accessed 2-10-09.

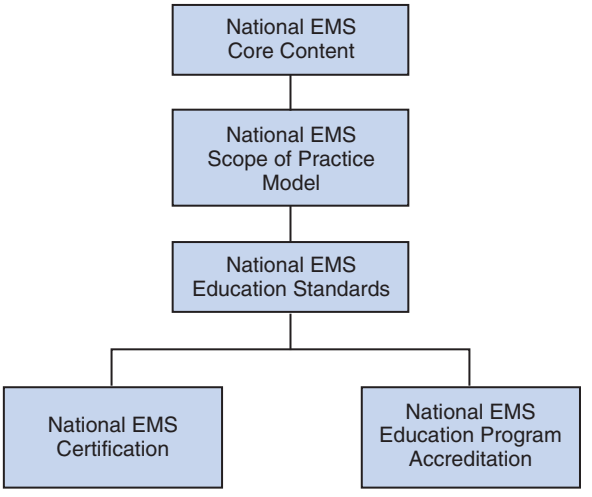

FIGURE 1-4 The five components of the EMS agenda. (National Registry of Emergency Medical Technicians; *Education Agenda for the Future, A Systems Approach*, Columbus, Ohio, 2000.)

BOX 1-6 Timeline of EMS Education Publications and Standards in the United States

- 1969: AAOS: Emergency Care and Transportation of the Sick and Injured (the "Orange Book")
- 1996: EMS Agenda for the Future
- 1971: EMT-Ambulance National Standard Curriculum
- 1998: National Standard Curriculum for EMT-Paramedic (revised)
- 2000: Education Agenda for the Future: A Systems Approach
- 2004: National EMS Practice Analysis
- 2005: National EMS Scope of Practice
- 2006: EMS at the Crossroads (Institute of Medicine [IOM]) report
- 2007: National EMS Scope of Practice
- 2009: National EMS Education Standards
- Supported by NHTSA for future implementation
  National EMS Certification
  National EMS Program Accreditation

Continuing Education

Continuing education provides a way for all health care practitioners to retain primary technical and professional skills. It also helps the paramedic move from competency (at graduation) to higher, more expert levels of practice. Continuing education aids in learning new and advanced skills and knowledge. Some skills learned during the initial course of study are not used often. New information, procedures, and resources that enhance patient care are continuously being developed to help maintain skill proficiency. Continuing education can take many forms, including the following:

- Conferences and seminars
- Lectures and workshops
- Quality improvement reviews
- Skill laboratories
- Certification and recertification programs
- Refresher training programs
- Journal studies
- Multimedia presentations
- Internet-based learning
- Case presentations
- Independent study

EMERGENCY MEDICAL SERVICES PERSONNEL LEVELS

Various levels of personnel and medical direction come together to make an effective prehospital EMS system. The levels include dispatcher, Emergency Medical Responder (EMR), Emergency Medical Technician (EMT), Advanced Emergency Medical Technician (AEMT), and Paramedic. Each EMS level described here has satisfied training based on the *National EMS Education Standards*. They function as part of a comprehensive EMS response, under **medical oversight**. (The following descriptions of EMS practitioner levels are adapted from the *National EMS Education Standards*.)[11]

Dispatcher

A dispatcher is a telecommunicator. This person serves as the primary contact with the public. The dispatcher directs the proper agencies to the scene. These agencies may include ground and air ambulances, fire departments, law enforcement, utility services, and others. The term *telecommunicator* applies to call takers, dispatchers, radio operators, data terminal operators, or any combination of such functions in a public service answering point located in a fire, police, or EMS communications center (see Chapter 5). An effective EMS dispatch communications system includes the following functions:

- *Receive and process calls for EMS assistance*. The dispatcher receives and records calls for EMS assistance and selects an appropriate course of action for each call. To do this, the dispatcher must obtain as much information as possible about the emergency event. This information

includes name, call-back number, and address. The dispatcher may also have to deal with distraught callers.

- *Dispatch and coordinate EMS resources*. The dispatcher directs the proper emergency vehicles to the correct address. This person also coordinates the emergency vehicles while en route to the scene, to the medical facility, and back to the operations base (Figure 1-5).
- *Relay medical information*. The dispatch center can provide a telecommunications channel among appropriate medical facilities and EMS personnel; fire, police, and rescue workers; and private citizens. This can consist of phone, radio, or biomedical telemetry.
- *Coordinate with public safety agencies*. The dispatcher aids communications between public safety (fire, law enforcement, rescue) and the EMS system. This coordinates services such as traffic control, escort, fire suppression, and extrication. The dispatcher must know the location and status of all EMS vehicles and whether support services are available. In larger systems, computer-aided dispatching is used. This provides for one or more of the following abilities:
  - Automatic entry of 9-1-1
  - Automatic interface to vehicle location with or without map display
  - Automatic interface to mobile data terminal
  - Computer messaging among multiple radio operators, call takers, or both
  - Dispatch note taking, reminder aid, or both
  - Ability to monitor response times, response delays, and on-scene times
  - Display of call information
  - Emergency medical dispatch review
  - Manual or automatic updates of unit status
  - Manual entry of call information
  - Radio control and display of channel status
  - Standard operating procedure review
  - Telephone control and display of circuit status

FIGURE 1-5 Computer dispatch screen.

Many EMS and public service agencies require specialized training for their dispatch personnel. The dispatcher then can give directions to the caller while the caller waits for EMS arrival. The training may include the USDOT training program for the emergency medical dispatcher, which is described further in Chapter 5.

CRITICAL THINKING

What type of dispatching is provided in your community? Are dispatchers trained to the level of emergency medical dispatcher?

Emergency Medical Responder (EMR)

The EMR (also known as First Responder) may be the first trained person in an EMS system to arrive on a scene. These responders may include personnel from fire departments and law enforcement agencies. They also may include designated commercial medical response teams, athletic trainers, and others. The primary focus of the EMR is to initiate immediate lifesaving care to critical patients who access the EMS system. This person has the basic knowledge and skills necessary to provide basic lifesaving interventions while awaiting additional EMS response. The EMR can also assist higher-level personnel at the scene and during transport. They perform basic interventions with minimal equipment. The EMR can do the following:

1. Recognize the seriousness of the patient's condition or extent of injuries.
2. Assess requirements for emergency medical care.
3. Administer appropriate emergency medical care for life-threatening injuries relative to airway, breathing, and circulation.

Emergency Medical Technician (EMT)

The EMT (formerly known as EMT-Basic) is trained in all phases of basic life support. This training includes the use of automated external defibrillators and the administration of some emergency medications. The primary focus of the EMT is to provide basic emergency medical care and transportation for critical and emergent patients who access the EMS system. They perform interventions with the basic equipment typically found on an ambulance. They also assist paramedics in the care of patients during transport.

Advanced Emergency Medical Technician (AEMT)

The AEMT was formerly known as EMT-Intermediate. The degree of training and skills that the AEMT practices varies between states and EMS systems. Training can include ALS procedures such as **peritracheal** airway adjuncts, intravenous therapy, defibrillation, cardiac rhythm interpretation,

and administration of some emergency medications. The primary focus of the AEMT is to provide basic and limited advanced emergency medical care and transportation for critical and emergent patients who access the EMS system.

Paramedic

The **paramedic** (formerly known as EMT-Paramedic) is trained in all aspects of basic and advanced life support procedures that are relevant to prehospital emergency care. The paramedic has advanced training in patient assessment, clinical decision making, cardiac rhythm interpretation, defibrillation, drug therapy, and airway management (Box 1-7). The paramedic provides emergency care based on advanced assessment skills and the formulation of a field diagnosis. The paramedic's specific roles and duties are discussed later in this chapter.

BOX 1-7 Description of the Paramedic Profession

The description of the paramedic profession provides the philosophy and rationale for the depth and breadth of coverage.

- Paramedics have fulfilled requirements prescribed by an accrediting agency to practice the art and science of out-of-hospital medicine under medical direction. Through performing assessments and providing medical care, their goal is to prevent and reduce mortality and morbidity caused by illness and injury. Paramedics primarily provide care to emergency patients in an out-of-hospital setting.
- Paramedics possess knowledge, skills, and attitudes consistent with the expectations of the public and the profession. Paramedics recognize that they are an essential component of the continuum of care and serve as linkages among health resources.
- Paramedics strive to maintain high-quality, reasonable-cost health care by delivering patients directly to appropriate facilities. As advocates for patients, paramedics seek to be proactive in affecting long-term health care by working with other provider agencies, networks, and organizations. The emerging roles and responsibilities of the paramedic include public education, health promotion, and participation in injury- and illness-prevention programs. As the scope of service continues to expand, the paramedic will function as a facilitator of access to care and as an initial treatment provider.
- Paramedics are responsible and accountable to medical direction, the public, and their peers. Paramedics recognize the importance of research and actively participate in the design, development, evaluation, and publication of research. Paramedics seek to take part in lifelong professional development, perform peer evaluation, and assume an active role in professional and community organizations.

From U.S. Department of Transportation, National Highway Transportation Administration: *EMT-Paramedic national standard curriculum*, Washington, DC, 1998, The Department.

NATIONAL EMERGENCY MEDICAL SERVICES GROUP INVOLVEMENT

Many groups and organizations help to set the standards of EMS (Box 1-8). These groups exist at the national, state, regional, and local levels. They take part in development, education, implementation, lobbying, and setting standards for EMS. Membership and participation in professional organizations help promote the professional status of the paramedic. These groups expose the paramedic to trends in emergency care, continuing education, and to resource experts. The organizations also provide for national representation. They have a unified voice in other health care organizations and issues of national matters. The EMS standard-setting groups have many roles. Their primary role, however, is to set standards with input from members of the profession and the community. By doing so, they help ensure that the public is protected from individuals and agencies that do not meet professional standards for licensure and/or certification.

One such organization is the National Registry of Emergency Medical Technicians (NREMT). The National Registry helps develop professional standards in the EMS industry. This organization verifies competencies for EMTs and paramedics by preparing and conducting certification examinations. The organization also simplifies the process of state-to-state mobility and reciprocity for its members.

BOX 1-8 Sampling of National Emergency Medical Services Organizations and Associations

American Ambulance Association
American College of Emergency Physicians
American College of Surgeons
Association of Air Medical Services
Emergency Nurses' Association
National Association of EMS Educators
National Association of EMS Physicians
National Association of Emergency Medical Technicians
International Association of Fire Chiefs
International Association of Fire Fighters
National Association of Search and Rescue
National Association of State EMS Officials
National Flight Nurses' Association
National Flight Paramedic Association
National Registry of Emergency Medical Technicians

DID YOU KNOW?

Every five years, the NREMT conducts a *National EMS Practice Analysis*. This has been done since 1994. The purpose of the study is to gather data on what EMS personnel actually do as part of their practice in providing emergency care. This helps the NREMT to revise and tailor their certification examinations. These data are also used in developing the EMS curricula that affect current practice.

The LEADS project is another important area of research conducted by the NREMT. LEADS stands for the *Longitudinal Emergency Medical Technician Attributes and Demographics Study*. The study is hosted by the NREMT and is conducted once each year. It is designed to describe the EMT population in the United States, their work activities, working conditions, and job satisfaction. The project began in August 1998. It is led by a team of researchers made up of state EMS directors, state EMS training coordinators, EMS system managers, emergency physicians, EMS educators, survey researchers, and staff of the NREMT. The NREMT is a leader in the areas of research in EMS education and practice. For more information about the Practice Analysis or LEADS study, see http://www.nremt.org.

CRITICAL THINKING

What issues do you think your national emergency medical services association should address to enhance patient care in your area?

LICENSURE, CERTIFICATION, AND REGISTRATION

Paramedics are granted permission to practice their skills by three processes: licensure, certification, and registration. The exact wording of granting this permission varies by state.

Licensure

Licensure is a process of regulating occupations. In this process a license is granted by a government authority. The license allows a person to engage in a profession or activity that otherwise would be unlawful. Some states and local authorities require that paramedics have a license.

Certification

Certification grants authority to a person to take part in an activity. The person receives a document from a government or nongovernment entity showing that the person has met the requirements to practice an activity. Some states or local authorities require that paramedics be certified.

NOTE

Some persons believe that licensed professionals have greater status than those who are certified or registered. This belief is unfounded. A certification granted by a state and conferring a right to engage in a trade or profession is in fact a license.

Registration

Registration is the act of enrolling one's name in a register, or book of record. For example, paramedics can be licensed or certified in their state and can be registered with the National Registry of Emergency Medical Technicians.

Credentialing

Credentialing is a local process that allows a paramedic to practice in a specific EMS agency (or setting). Credentialing processes are typically guided by the local medical director (Figure 1-6).

PROFESSIONALISM

Training and performance standards have helped to define EMTs and paramedics as health care professionals. The term *profession* refers to a body of knowledge or expertise. The members of such a field are often self-regulated through licensing or certification that confirms competence. In addition, most professions adhere to standards. These standards include initial and continuing education requirements. *Professionalism* refers to the way in which a person follows the standards of a profession. These standards may include conduct and performance standards. These standards also usually include adhering to a **code of ethics** approved by the profession (see Chapter 7).

Health Care Professionals

Health care professionals conform to the standards of their profession. By providing quality patient care and striving for high standards, they instill pride in the profession and earn the respect of others. EMS professionals occupy positions of public trust and are highly visible role models. As

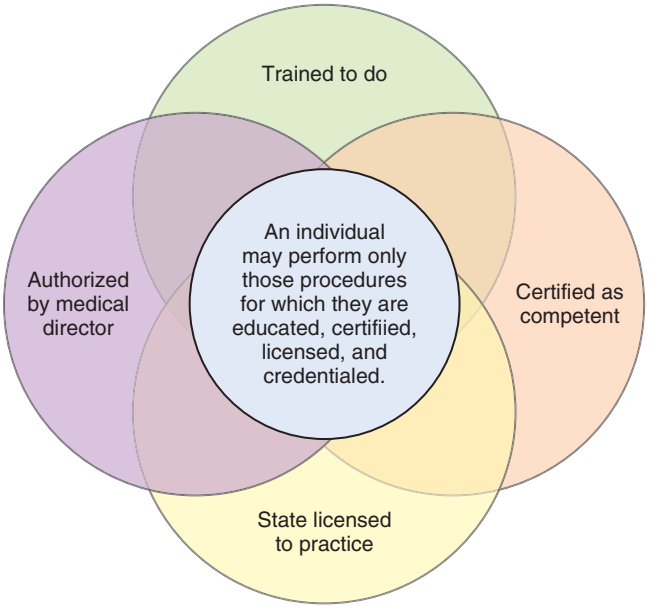

FIGURE 1-6 The relationship among education, certification, licensure, and credentialing.

such, the public has high expectations of EMTs and paramedics while they are both "on" and "off" duty. Therefore, professional conduct at all times and a commitment to excellence in daily activities complement the image of the EMS professional. Image and behavior are vital to establishing credibility and instilling confidence. The professional paramedic represents his or her employer; the EMS agency; the state, county, city, or district EMS office; and his or her peers.

Attributes of the Professional Paramedic

Many aspects of being professional can be applied to the role of the paramedic. Eleven of these attributes follow:[10]

1. *Integrity*. Integrity means being honest in all actions. Integrity may be the most important behavior for EMS professionals. The public assumes EMS professionals have integrity. Actions that show integrity include being truthful, not stealing, and providing complete and correct documentation.
2. *Empathy*. Empathy is identifying with and understanding the feelings, situations, and motives of others. EMS professionals must always show empathy to patients, families, and other health care professionals. Behavior that demonstrates empathy includes showing caring, compassion, and respect for others; understanding the feelings of the patient and family; being calm and helpful to those in need; and being supportive and reassuring of others.
3. *Self-motivation*. Self-motivation is the internal drive for merit and self-direction. Self-motivation can mean taking the lead to finish tasks, to improve behavior, and to follow through without supervision. Some marks of self-motivation are showing enthusiasm for learning, being committed to **continuous quality improvement** or CQI (described later in this chapter), and accepting constructive feedback.
4. *Appearance and personal hygiene*. Paramedics are aware of how they present themselves as representatives of their profession. They must ensure that their clothing and uniforms are clean and in good repair. They must be aware of the importance of personal hygiene and good grooming.
5. *Self-confidence*. Paramedics must trust and rely on themselves, often in difficult situations. One key task is to assess personal and professional strengths and weaknesses. The ability to trust personal judgment shows self-confidence.
6. *Communications*. An important part of the paramedic's job is communicating. Paramedics must be able to convey key information to others verbally and in writing. They must demonstrate communication skills by speaking clearly, writing legibly, and listening actively. Finally, paramedics must be able to adjust communication strategies to various situations.
7. *Time management*. Time management refers to organizing and prioritizing tasks to make the best use of time. Examples include being punctual and completing tasks and assignments on time.
8. *Teamwork and diplomacy*. The paramedic must be able to work well with others to achieve common goals. As a member of the EMS team, the paramedic must place the success of the team above personal success. This is done by supporting and respecting other team members, being flexible and open to change, and communicating with co-workers to resolve problems. (See Chapter 5.)
9. *Respect*. Respect means having regard for others and showing consideration and appreciation. Paramedics are polite to others and avoid the use of derogatory or demeaning terms. They know that showing respect brings credit to themselves, their association, and their profession.
10. *Patient advocacy*. The paramedic must always act as the patient's advocate, even when the patient disagrees with the care. Paramedics should not attempt to impose their personal beliefs on patients or allow personal biases (religious, ethical, political, social, legal) to impact patient care. The needs of the patient are always placed above self-interests. The paramedic also must protect the patient's confidentiality.
11. *Careful delivery of service*. Paramedics deliver the highest quality of patient care. With this care comes attention to detail and proper prioritization of care. They also must evaluate their performance and attitude on every call. As part of the careful delivery of service, paramedics master and refresh their skills; perform full equipment checks; and ensure safe ambulance operations. Paramedics also follow policies, procedures, and protocols and comply with the orders of their supervisors.

CRITICAL THINKING

Which of these professional attributes represent your strengths? Which ones do you think you need to work on?

ROLES AND RESPONSIBILITIES OF THE PARAMEDIC

The paramedic may practice patient care at an emergency scene, from an emergency scene to the hospital, between health care facilities, or in other health care settings as permitted by state and local laws. The paramedic's roles and duties can be divided into two groups: primary responsibilities and additional responsibilities[10] (Box 1-9).

Primary Responsibilities

The paramedic must be prepared physically, mentally, and emotionally for the job. Preparation includes being committed to positive health practices (see Chapter 2). It also includes having the proper equipment and supplies

BOX 1-9 Roles and Responsibilities of the Paramedic

Primary Responsibilities	Additional Responsibilities
Preparation	Community involvement
Response	Support of primary care efforts
Scene assessment	Advocation of citizen involvement in emergency medical services
Patient assessment	Participation in leadership activities
Recognition of injury or illness	Personal and professional development
Patient management	
Appropriate patient disposition	
Patient transfer	
Documentation	
Returning to service	

BOX 1-10 Sampling of Specialized Care Facilities

- Burn specialization center
- Cardiac treatment center
- Clinical laboratory service
- Emergency department
- Facility with acute hemodialysis capability
- Facility with acute spinal cord or head injury management capability
- Facility with reperfusion capability
- Facility with special radiological capabilities
- High-risk obstetrical facility
- Hyperbaric treatment center
- Intensive care unit for trauma patients
- Neurology center
- Operating suite
- Pediatric facility
- Postanesthesia recovery room or surgical intensive care unit
- Psychiatric facility
- Rehabilitation facility
- Stroke center
- Toxicology (including hazardous material or decontamination) service
- Trauma center

and maintaining adequate knowledge and skills of the profession. The paramedic must respond to the scene in a safe and timely manner. Scene assessment must consider personal safety; safety of the crew, patients, and bystanders; and the mechanism of injury or probable cause of illness.

The paramedic must quickly perform patient assessment to determine the injury or illness. Integrating assessment findings with knowledge of disease or injury helps the paramedic formulate a field impression. It also helps set priorities of care and transportation. Managing an emergency often entails following protocols and interacting with medical direction as needed. The care provided by the paramedic should minimize secondary injury. After stabilizing the patient in the field, the paramedic should provide for transport to an appropriate facility. Transportation may include a ground or air ambulance. The type of transport needed for optimal patient care is based on the patient's condition, distance from the hospital, travel time, and other factors. Choosing the most appropriate facility requires knowledge of available resources, hospital designations, and categorization (Box 1-10). The hospital destination decision should be made jointly between the paramedic and the patient in cooperation with medical oversight. Knowledge of transfer agreements and local transport protocols is also helpful.

The paramedic is the patient's advocate as responsibility for care shifts to the staff at the receiving facility. The staff must be briefed about the patient's condition at the scene and during transport. The paramedic also needs to provide thorough and accurate documentation in the **patient care report** (PCR). The PCR should be completed in a timely manner so that the EMS crew can return to service. The crew should prepare the ambulance for return to service by replacing equipment and supplies (per agency protocol). The crew also should review the call openly. This can help to identify ways to improve the patient care services that were provided at the scene and during transport.

Additional Responsibilities

Other duties of the paramedic include community involvement, support of primary care efforts, advocating citizen involvement in the EMS system, participation in leadership activities, and personal and professional development.

A paramedic can be involved in the community and can be a role model for the profession in many ways. The paramedic can advocate illness and injury prevention programs (see Chapter 3) and can participate as a leader in community activities. A few ways to improve the health of the community include teaching CPR, first aid, and injury prevention. These activities help to ensure proper use of EMS resources. They can also improve the integration of EMS with other health care and public safety agencies.

Communities and their health care organizations often enlist paramedics to support primary care efforts, and prevention and wellness programs. Paramedics can help to inform the public of the best use of prehospital and other non-EMS health care resources. Examples include alternatives to ambulance transportation, nonhospital emergency department clinical providers, and freestanding emergency clinics. These programs that teach when, where, and how to use EMS and emergency departments promote the best use of health care resources.

Encouraging citizens to be involved in EMS improves the system as a whole. Citizens can help to set the needs and parameters for EMS use in the community. They can offer an objective view into quality improvement and problem solving. In addition, having involved citizens creates informed, independent advocates for the EMS system.

NOTE

Some EMS agencies organize community emergency response teams (CERTs). These teams help prepare citizens to respond to disaster-type emergencies. Members are trained to provide instant help to victims, organize volunteers, and support first responder efforts.

SHOW ME THE EVIDENCE

Researchers asked nationally registered EMS professionals how much contact they had with their medical director in the previous 6 months. For that period 62.5% of respondents indicated contact with the medical director during education, a call review, or on the scene. Paramedics were more likely (78.5%) than EMT-Intermediates (62.3%) or EMT-Basics (47.6%, $p < 0.001$) to have had contact with the medical director. Urban EMS professionals were more likely to have had MD contact than rural respondents (64.9% vs. 59.2%, $p < 0.001$).

From: Studnek JR, Fernandez AF, Margolis GS, O'Connor RE: Describing the amount of medical director contact among nationally registered emergency medical services professionals. Abstract published in *Prehosp Emerg Care,* 12(1): 115, 2008.

Paramedics can take part in leadership activities in their communities in many ways. One example is conducting primary injury prevention initiatives (activities and risk surveys). Another example is assisting media campaigns to promote EMS issues and other health programs. (See Chapter 3.)

Finally, a paramedic has a responsibility for personal and professional development. There are many methods to accomplish this. Examples include continuing education, student mentoring, membership in professional organizations, and joining professional teams. Other methods include becoming involved in work-related issues that affect career growth, exploring alternative career paths in the EMS profession, conducting and supporting research initiatives, and being actively involved in legislative issues related to EMS.

MEDICAL DIRECTION FOR EMERGENCY MEDICAL SERVICES

The medical direction physician is the medical leader for the EMS system. The physician serves as a resource and as a patient advocate. This relationship between medical direction and the paramedic is critical to an effective EMS system. It allows for the delivery of advanced prehospital care. The ideal medical direction physician is properly educated as an EMS medical director. The physician also is motivated to provide the following[12]:

- EMS system design and operations
- Education and training of EMS personnel
- Participation in personnel selection
- Participation in equipment selection
- Development of clinical protocols in cooperation with expert EMS personnel
- Participation in CQI and problem resolution
- Direct input into patient care
- Interface between EMS systems and other health care agencies
- Advocacy within the medical community
- Guidance as the "medical conscience" of the EMS system (advocating for quality patient care)

Types of Medical Direction

The two types of medical direction are **online (direct) medical direction** and **off-line (indirect) medical direction.**[13] Both types ensure the quality of medical care in an EMS system. Most prehospital care is provided through standing orders and patient care protocols (varies by state). There are times, however, when a patient care issue falls outside the scope of standing orders or an unusual situation at the scene arises. When this occurs, the paramedic may need to contact online medical direction by radio or phone to convey the patient's information and to receive orders through direct consultation with a physician or physician designee. This designee may be a registered nurse or physician assistant. The designee also may be a paramedic trained to give ALS orders in the medical direction system. Online medical direction allows for instant and specific care, telemetry, and CQI while paramedics are on the scene. As a rule, online medical direction supersedes off-line medical direction.[14]

An advisory group often is the voice behind the off-line direction, but it also can be provided by one or more medical directors. A director must have full medical direction authority. He or she also must have knowledge of how the EMS system operates. This type of direction can be *prospective* or *retrospective*. Prospective off-line direction covers the authority to set **treatment protocols** and **standing orders** (Box 1-11). Such knowledge includes training for care and triage in the prehospital arena, as well as the choice of equipment, supplies, and personnel. Retrospective off-line direction includes any actions that take place after the EMS call. An example is reviewing a patient care report and providing CQI.

On-Scene Physicians

Some of the first ambulance personnel were physicians. Yet, rarely is a medical direction physician on the scene providing direct field supervision of EMS personnel. At times, however, a physician (*physician intervenor*) may witness the injury or illness. Perhaps the patient's private physician is on the scene when EMS arrives. When this occurs, positive

BOX 1-11 Protocols

Treatment protocols are written guidelines that define the scope of prehospital care for emergency medical services (EMS) personnel. The medical director of the EMS or members of a regional EMS advisory group create them. The paramedic must adhere to these protocols. The paramedic must follow the protocols unless advised otherwise by medical direction.

Standing orders are more specific than protocols. Standing orders usually are included in a protocol when a delay in treatment would harm the patient. Most protocols and standing orders comply with national standards. They also comply with state EMS medical practice arts and regional guidelines. An example of a national standard is the American Heart Association guidelines for advanced cardiac life support. Another is the American College of Surgeons standards for advanced trauma life support. Protocols define the standard of care for paramedic crews and online physicians. The cases in which the paramedic acts strictly by standing orders usually are few. These situations may include intubation of a nonbreathing patient or first-line medication administration in cardiac arrest. Situations also may include events in which radio contact has failed and a delay could threaten the patient outcome.

interaction between the on-scene physician and the EMS crew is essential.

NOTE

An on-scene physician may not be familiar with functions of emergency medical services or medical oversight responsibilities. The lines of authority and responsibility for these physicians vary from state to state. Each EMS agency should have a policy that defines interaction with physicians on the scene.

If a nonmedical direction physician or the patient's physician is on the scene, EMS personnel must follow protocols. If no protocols are in place, the paramedic should immediately contact online medical direction. The policies of many EMS agencies require that the physician on the scene can assume responsibility for patient care and provide medical direction.[15] Together the physicians can make choices about the patient's care. With permission of medical direction, a physician on the scene may take control of the patient's care. If a physician on the scene tries to direct care in opposition to medical direction, EMS personnel should have law enforcement intervene. This will ensure that the scene is safe and the EMS care goes uninterrupted.

IMPROVING SYSTEM QUALITY

A major goal of any EMS system is to evaluate and improve care continually. One way to meet this goal is through a modified form of quality assurance. This form of quality assurance is known as *continuous quality improvement* (CQI), which is the ongoing study and improvement of a process, system, or organization (Box 1-12).

BOX 1-12 Quality Assurance and Continuous Quality Improvement

Quality assurance (QA) is a system of quality management that by tradition was linked with spotting deviations from a standard (e.g., protocols). Quality assurance also altered these deviations through some type of punitive action. Continuous quality improvement (CQI) is a modified form of QA. Continuous quality improvement focuses on the system and not the individual, thus removing much of the punitive aspect associated with a QA program. Continuous quality improvement is less rigid than QA. In addition, CQI considers many factors that often apply to EMS. Continuous quality improvement includes the entire medical direction system and involves all health providers in the problem-solving process.

The EMS worker should use input from CQI activities to adapt treatment protocols and educational activities when needed. The goal of CQI is to find and fix problems in a positive manner. Continuous quality improvement also is aimed at improving the overall system. CQI activities include a review of the following:

- Outcome measures of prehospital care (e.g., scene times, procedure completion rates, and mortality reviews)
- Care while treatment is ongoing (concurrent reviews)
- Written EMS patient care paperwork (retrospective reviews)
- Random or selected radio communication tapes
- New procedures, equipment, or therapies

A CQI program identifies and attempts to improve problems in certain areas. Key areas that are monitored in most EMS systems include:

- Medical direction
- Financing
- Training
- Communications
- Prehospital management and transportation
- Interfacility transportation
- Receiving facilities
- Specialty care units
- Dispatch
- Public information and education
- Audit and quality assurance
- Disaster planning and mutual aid

Continuous quality improvement is a process that involves all caregivers in the problem-solving aspect (Figure 1-7). Continuous quality improvement stresses the value of enabling frontline personnel to perform their jobs well. With this group approach, all parties can be involved in elaborating on the cause of the problem. They can work together to develop remedies and can design a course of action to correct the problem. Then they can enforce the plan and reexamine the issue to see whether the problem has been resolved.

CRITICAL THINKING

The number of needle-stick injuries in your agency has increased. How might the continuous quality improvement process affect this situation?

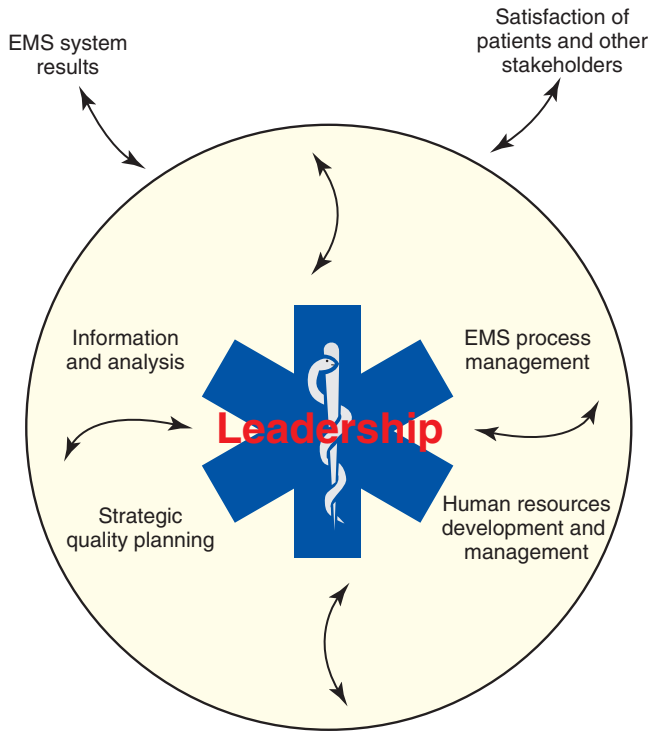

FIGURE 1-7 Leadership guide to quality improvement for EMS. (U.S. Department of Transportation, Health Resources and Services Administration, Maternal and Child Health Bureau, *A leadership guide to quality improvement,* Washington, DC, 1999, The Administration.)

Key actions or categories for EMS leaders to improve quality within their organization are as follows[9]:

1. *Leadership* involves efforts by senior leadership and management. These persons lead by example to integrate CQI into the strategic planning process and throughout the entire organization. Such integration promotes quality values and CQI techniques in work practices.
2. *Information and analysis* deal with managing and using the data needed for effective CQI. Continuous quality improvement is based on management by fact. Thus information and analyses are critical to CQI success.
3. *Strategic quality planning* has three main parts. The first is developing long- and short-term goals for structural, performance, and outcome quality standards. The second is finding ways to achieve those. The third is measuring the effectiveness of the system in meeting quality standards.
4. *Human resource development and management* refers to developing the full potential of the EMS workforce. This effort is guided by the principle that the entire EMS workforce is motivated to achieve new levels of service and value.
5. *Emergency medical services process management* concerns the creation and maintenance of high-quality services. Within the context of CQI, process management refers to the improvement of work activities. Process management also refers to improving work flow *across* functional or departmental boundaries.
6. *Emergency medical systems results* entail assessment of the quality results achieved and examining the success of the organization in achieving CQI.
7. *Satisfaction of patients and other stakeholders* involves ensuring ongoing satisfaction. Those internal and external to the EMS system must be satisfied with the services provided.

Benefits gained by applying these seven guidelines and recommendations are many. They include improvements in service and patient care delivery, economic efficiency, and profitability. They also help improve patient and community satisfaction and loyalty, and healthful outcomes.

SHOW ME THE EVIDENCE

The 2007 U.S. Metropolitan Municipalities' EMS Medical Directors' Consortium describe an evidence-based model to measure quality within suburban and urban EMS systems. They include specific key interventions and numbers-needed-to-treat that should be measured in the areas of ST-elevation myocardial infarction (STEMI), pulmonary edema, asthma, seizure, trauma, and cardiac arrest. The interventions to be evaluated in CQI are those that have been demonstrated by research to have a positive impact on patient outcome. For example, in a patient with trauma, prehospital records should be evaluated for scene time <10 minutes and transport to a trauma center.

From: Myers JB, Slovis CM, Eckstein M, et al: Evidence-based performance measures for emergency medical services systems: a model for expanded EMS benchmarking, *Prehosp Emerg Care* 12(2): 141-151, 2008.

PATIENT SAFETY

Patient safety is one of the most urgent health care challenges. In 1996, the Institute of Medicine (IOM) launched an ongoing effort to assess and improve the nation's quality of care. The report brief of this initiative is titled *To Err is Human: Building a Safer Health System*. This study found that[16]:

- Health care in the United States is not as safe as it should be—and can be.
- At least 44,000 people, and perhaps as many as 98,000 people, die in hospitals each year as a result of medical errors that could have been prevented.
- Preventable medical errors in hospitals exceed attributable deaths to such feared causes as motor-vehicle wrecks, breast cancer, and AIDS.
- High error rates with serious consequences are most likely to occur in intensive care units, operating rooms, and emergency departments.
- Most errors are caused by faulty systems, processes, and conditions (Box 1-13).

High-Risk Activities

There are many activities that can lead to medical errors in EMS. Some of the more high-risk activities include:

BOX 1-13 Types of Errors

Diagnostic
- Error or delay in diagnosis
- Failure to employ indicated tests
- Use of outmoded tests or therapy
- Failure to act on results of monitoring or testing

Treatment
- Error in the performance of an operation, procedure, or test
- Error in administering the treatment
- Error in the dose or method of using a drug
- Avoidable delay in treatment or in responding to an abnormal test
- Inappropriate (not indicated) care

Preventive
- Failure to provide prophylactic treatment
- Inadequate monitoring or follow-up of treatment

Other
- Failure of communication
- Equipment failure
- Other system failure

Types of Errors from IOM report, http://www.iom.edu/Object.File/Master/4/117/ToErr-8pager.pdf, accessed August 26, 2010.

- Ambulance crashes
- Dropping patients
- Hand-offs
- Communication issues
- Medication issues
- Poor sterile technique
- Airway issues
- Spinal immobilization

DID YOU KNOW?

Hand-offs involve the transfer of rights, duties, and obligations from one person or team to another. Hand-offs should include the continuity and safety of the patient's care. For hand-offs to be effective, a solid foundation in communications is necessary. Face-to-face communications through a standardized process is the best way to transfer patient care. This should include an opportunity to ask and respond to questions. The hand-off includes current information about the patient, such as care, treatment, condition, and recent or anticipated changes in the patient's condition. A memory aid that can be used to provide structure in handoffs is *I Pass the Baton* (Figure 1-8).[17]

Most errors can be avoided by maintaining skill proficiency; by following established rules and protocols; by maintaining team communications; and by ensuring an adequate knowledge base in patient care procedures and related EMS duties. Patient safety issues will be discussed throughout this text.

SHOW ME THE EVIDENCE

Researchers in the UK surveyed four emergency departments and one ambulance service to investigate the hand-over process from ambulance personnel to the ED staff. They found a lack of active listening skills in the ED staff led to frustration of the EMS crews. They report that ambulance staff should be prepared to repeat their report, especially for seriously ill or injured patients. Reports for critically ill patients should be delivered in two phases: with essential information reported at the time of handoff and more detailed information conveyed after initial care of the patient in the ED has begun. They recommend more ED education on this process.

From: Jenkin A, Abelson-Michell N, Cooper S: Patient handover: time for a change? *Accid Emerg Nurs* 15(3): 141-147, 2007.

I PASS the BATON

I	Introduction	Individuals involved in the handoff identify themselves, their roles and jobs
P	Patient	Name, identifiers, age, sex, location
A	Assessment	Present chief complaint, vital signs, symptoms, and diagnosis
S	Situation	Current status and circumstances, including code status, level of certainty or uncertainty, recent changes, and response to treatment
S	Safety concerns	Critical lab values and reports, socioeconomic factors, allergies and alerts, such as risk for falls
the		
B	Background	Comorbidities, previous episodes, current medications, and family history
A	Actions	Detail what actions were taken or are required and provide a brief rationale for those actions
T	Timing	Level of urgency and explicit timing, prioritization of actions
O	Ownership	Who is responsible (nurse/doctor/team), including patient and family responsibilities?
N	Next	What will happen next? Any anticipated changes? What is the plan? Any contingency plans?

FIGURE 1-8 Transferring patient care safely.

Preventing Medical Errors

Patient safety solutions have been developed by the World Health Organization (WHO), in collaboration with the Joint Commission, and The Joint Commission International. This group defined *patient safety solutions* as: "Any system design or intervention that has demonstrated the ability to prevent or mitigate patient harm stemming from the processes of health care." In 2007, the International Steering Committee approved nine solutions for patient safety (Box 1-14).[18]

BOX 1-14 Nine Patient Safety Solutions

1. **Look-Alike, Sound-Alike Medication Names:** Confusing drug names is one of the most common causes of medication errors and is a worldwide concern. With tens of thousands of drugs currently on the market, the potential for error created by confusing brand or generic drug names and packaging is significant.
2. **Patient Identification:** The widespread and continuing failures to correctly identify patients often leads to medication, transfusion, and testing errors; wrong person procedures; and the discharge of infants to the wrong families.
3. **Communication During Patient Hand-Overs:** Gaps in hand-over (or hand-off) communication between patient care units, and between and among care teams, can cause serious breakdowns in the continuity of care, inappropriate treatment, and potential harm for the patient.
4. **Performance of Correct Procedure at Correct Body Site:** Considered totally preventable, cases of wrong procedure or wrong site surgery are largely the result of miscommunication and unavailable, or incorrect, information. A major contributing factor to these types of errors is the lack of a standardized preoperative process.
5. **Control of Concentrated Electrolyte Solutions:** Although all drugs, biologics, vaccines, and contrast media have a defined risk profile, concentrated electrolyte solutions that are used for injection are especially dangerous.
6. **Assuring Medication Accuracy at Transitions in Care:** Medication errors occur most commonly at transitions. Medication reconciliation is a process designed to prevent medication errors at patient transition points.
7. **Avoiding Catheter and Tubing Misconnections:** The design of tubing, catheters, and syringes currently in use is such that it is possible to inadvertently cause patient harm through connecting the wrong syringes and tubing and then delivering medication or fluids through an unintended wrong route.
8. **Single Use of Injection Devices:** One of the biggest global concerns is the spread of human immunodeficiency virus (HIV), the hepatitis B virus (HBV), and the hepatitis C virus (HCV) because of the reuse of injection needles.
9. **Improved Hand Hygiene to Prevent Health Care-Associated Infection (HAI):** It is estimated that at any point in time more than 1.4 million people worldwide are suffering from infections acquired in hospitals. Effective hand hygiene is the primary preventive measure for avoiding this problem.

Methods to Help Prevent Medical Errors in EMS

Methods to avoid medical errors in EMS can be grouped into environmental methods and individual methods.

Environmental methods that can help prevent medical errors include having clear and established protocols for procedures; ensuring that there is sufficient lighting for patient assessment and patient care procedures; and performing patient care duties with minimal interruptions. Organizing and packaging drugs (e.g., separating adult and pediatric drugs) to avoid confusing the medications is another example of an environmental method to reduce medical errors. Another example of a safety method to reduce medical error is securing equipment in the patient compartment of the ambulance. Another is safely securing adult and pediatric patients during transport.

DID YOU KNOW?

Medication Error Survey: Paramedic Self-Reported Medication Errors

BACKGROUND: Continuing quality improvement (CQI) reviews reflect that medication administration errors occur in the prehospital setting. These include errors involving dose, medication, route, concentration, and treatment.

METHODS: A survey was given to paramedics in San Diego County. The survey tool was established on the basis of previous literature reviews and questions developed with previous CQI data.

RESULTS: A total of 352 surveys were returned, with the paramedics reporting a mean of 8.5 years of field experience. They work an average of 11.0 shifts/month with an average of 25.4 hours and 6.7 calls/shift. Thirty-two (9.1%) responding paramedics reported committing a medication error in the last 12 months. Types of errors included dose-related errors (63%), protocol errors (33%), wrong route errors (21%), and wrong medication errors (4%). Issues identified as contributing to the errors include failure to triple check, infrequent use of the medication, dosage calculation error, and incorrect dosage given. Fatigue, training, and equipment setup of the drug box were not listed as contributing factors. The majority of these errors were self-reported to the CQI representative (79.1%), with 8.3% being reported by the base hospital radio nurse, 8.3% found upon chart review, and 4.2% noted by paramedic during call but never reported.

CONCLUSIONS: Nine percent of paramedics responding to an anonymous survey report medication errors in the last 12 months, with 4% of these errors never having been reported in the CQI process. Additional safeguards must continue to be implemented to decrease the incidence of medication errors.

From: Vilke GM, Tornabene SV, Stepanski B, et al: Paramedic self-reported medication errors, *Prehosp Emerg Care* 11(1):80-84, 2007.

Individual methods include personal activities to improve patient safety. These include:

- **Reflection in action:** Think during an event (during action) when things do not go as planned. Reflection in action allows us to reshape what we are working on *while*

we are working on it. It helps us as we complete a task. Reflection in action promotes critical thinking and bridges the gap between "knowing and doing."

- **Question assumptions:** Apply critical thinking to continuously look for good ideas and new solutions. This will help to set priorities and to problem solve.
- **Reflection bias ("hindsight" bias):** Avoid the tendency to judge an event, because a bad outcome is known from a previous experience you had. *("I knew that was going to happen.")* Reflection bias is the inclination to see events that have occurred in the past as more predictable than they really were. Review the events after the fact and you might foresee the outcome as more preventable. Replace hindsight with insight.
- **Use decision aids:** Use evidence-based decision aids and guidelines (e.g., algorithms, pocket guides) to simplify decision making and improve patient safety. Decision aids can also facilitate patients' participation in decisions about their care, when appropriate.
- **Ask for help:** You are functioning as part of a team. Don't be hesitant to ask your crew members or medical direction for help or advice, if the need arises. If you are unsure about a decision, drug dose, or procedure, remember that patient safety comes first.

SUMMARY

- The roots of prehospital emergency care may date back to the military.
- In the early twentieth century through the mid-1960s, prehospital care in the United States was provided in a few ways. Care was provided mostly by urban hospital-based systems. These systems later developed into municipal services. Care also was provided by funeral directors and volunteers who were not trained in these services.
- The operations of an effective EMS system include citizen activation, dispatch, prehospital care, hospital care, and rehabilitation.
- Each level of EMS personnel have their own distinct roles and duties. These roles include telecommunicators (dispatchers), emergency medical responders, EMTs, advanced EMTs, and paramedics. These levels combine to make an effective prehospital EMS system.
- Many professional groups and organizations help to set the standards of EMS. These groups exist at the national, state, regional, and local levels. The groups take part in development, education, and implementation. Being active in such a group helps to promote the status of the paramedic.
- Continuing education is crucial. It provides a way for all health care personnel to maintain basic technical and professional skills.
- Professionalism refers to the way in which a person conducts himself or herself. Professionalism also refers to how one follows the standards of conduct and performance established by the profession.
- The roles and duties of the paramedic can be divided into two categories: *primary* and *additional* duties.
- The two types of medical direction are online (direct) and off-line (indirect). Both are equally important. They help to ensure that the components of quality medical care are in place in an EMS system.
- A CQI program identifies and attempts to resolve problems in areas such as medical direction, financing, training, communication, prehospital management and transportation, interfacility transfer, receiving facilities, specialty care units, dispatch, public information and education, audit and quality assurance, disaster planning, and mutual aid.
- Patient safety should be a high priority during every call. Errors that may cause injury or illness often involve handoffs, communication issues, medication issues, airway issues, lifting or moving patients, ambulance crashes, and immobilization.

CHAPTER

2 Well-Being of the Paramedic

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the components of wellness and associated benefits.
2. Discuss the paramedic's role in promoting wellness.
3. Outline the benefits of specific lifestyle choices that promote wellness, including proper nutrition, weight control, exercise, sleep, and smoking cessation.
4. Identify risk factors and warning signs of cancer and cardiovascular disease.
5. List measures to take to reduce the risk of infectious disease exposure.
6. Outline actions to be taken following a significant exposure to a patient's blood or other body fluids.
7. Identify preventive measures to minimize the risk of work-related illness or injury associated with exposure, lifting and moving patients, hostile environments, vehicle operations, and rescue situations.
8. List signs and symptoms of addiction and addictive behavior.
9. Describe guidelines for working effectively in a diverse workplace.
10. Distinguish between normal and abnormal anxiety and stress reactions.
11. Give examples of stress-reduction techniques.
12. Outline the 10 components of critical incident stress management.
13. Given a scenario involving death or dying, identify therapeutic actions you may take based on your knowledge of the dynamics of this process.

KEY TERMS

adaptation A cellular response to stress of any kind to escape and protect from injury; a central part of the response to changes in the physiological condition.

addiction A compulsive, uncontrollable dependence on a substance, habit, or practice to such a degree that cessation causes severe emotional, mental, or physiological reactions.

adrenaline An endogenous adrenal hormone that helps prepare the body for energetic action.

anxiety A state or feeling of apprehension, uneasiness, agitation, uncertainty, or fear resulting from the anticipation of some threat or danger.

autonomic nervous system The part of the nervous system that regulates involuntary vital functions, including the activity of cardiac muscle, smooth muscle, and glands.

circadian rhythm A pattern based on a 24-hour cycle, especially repetition of certain physiological phenomena, such as sleeping and eating.

distress Negative, debilitating, or harmful stress.

eustress Positive, performance-enhancing stress.

posttraumatic stress disorder An anxiety disorder that can occur following a traumatic event.

stress A nonspecific mental or physical strain caused by any emotional, physical, social, economic, or other factor that initiates a physiological response.

universal precautions Infection control practices in health care that are observed with every patient and procedure and that prevent exposure to blood-borne pathogens.

The paramedic has a demanding job that requires physical and mental well-being. By adopting a lifestyle that enhances personal wellness, paramedics can improve their health and prolong their careers. A healthful lifestyle also helps paramedics to serve as role models and coaches for others.

WELLNESS COMPONENTS

Wellness has two main aspects: physical well-being and mental and emotional health. Both aspects are key to the paramedic's personal health and ability to safely deliver emergency care. They are also important to manage stressful events that are inherent in the profession.

Physical Well-Being

Several factors play a major role in maintaining physical health. These factors include good nutrition, physical fitness, ample sleep, and the prevention of disease and injury.

NUTRITION

Nutrients are foods that hold the elements necessary for body function. The six categories of nutrients are carbohydrates, fats, proteins, vitamins, minerals, and water.

Carbohydrates are composed of carbon, hydrogen, and oxygen. Carbohydrates are obtained primarily from plant foods. The only important source of animal carbohydrates is lactose (milk sugar). Plants store carbohydrates as starch. Starch is made up of granules enclosed by cellulose walls that swell and burst when cooked. This feature makes cooked starchy foods easier to digest than raw, uncooked starchy foods.

All dietary fats contain a mixture of saturated and unsaturated fatty acids. Saturated fats are found mainly in meat and dairy products and in some vegetable fats. These fats raise the cholesterol levels in the blood by shutting down the process that normally removes excess cholesterol from the body. Unsaturated fats are subdivided further into polyunsaturated and monounsaturated fats. Polyunsaturated fats are found in safflower, sunflower, corn, soybean, and cottonseed oils and in some fish. These fats help rid the body of newly formed cholesterol. Omega-3 fatty acids are found mainly in cold-water fish such as tuna, salmon, and mackerel. These fats are a form of polyunsaturated fats. All polyunsaturated fats, including the omega-3 fats, are considered important to human health. Monounsaturated fats are liquid vegetable oils. Examples of these fats include canola and olive oils. Like polyunsaturated fats, these also may decrease blood cholesterol levels (Box 2-1). Trans-fats are unsaturated fatty acids formed when vegetable oils are processed and made more solid or into a more stable liquid. Trans-fats are present in a wide range of foods. These foods include those products made with partially hydrogenated oils, such as baked goods and fried foods, and some margarine products. Trans-fats also occur naturally in low amounts in meats and dairy products. Although trans-fats are unsaturated, they appear similar to saturated fats in terms of their effect on blood cholesterol levels.

NOTE

Cholesterol is present in all foods of animal origin and is concentrated heavily in fat and in poultry skin. Cholesterol is a white, waxy substance found in every cell. Not all cholesterol is harmful; an adequate amount of cholesterol is needed for body functions. Cholesterol is manufactured in the liver and is carried through the bloodstream. Adding cholesterol to the diet can raise blood cholesterol levels and increase the risk of heart disease and stroke.

Proteins are made of hydrogen, oxygen, carbon, and nitrogen (and most contain sulfur and phosphorus). Proteins are vital to building body tissue during growth, maintenance, and repair. When proteins are digested, they break down into amino acids (classified as *essential* or *nonessential*). Essential amino acids are needed for body growth and cellular life. They must be obtained in food because they are *not* made in the body. Nonessential amino acids are not needed for body health and growth and can be made in the body. Proteins that contain all the essential amino acids are *complete proteins* and are found in meats and dairy products. Proteins that are missing one or more essential amino acids are *incomplete proteins* (e.g., those in grains and vegetables).

BOX 2-1 A Primer on Fats and Oils

Not All Fats and Oils Are Created Equal

Fats and oils are made up of basic units called fatty acids. Each type of fat or oil is a mixture of different fatty acids.

- **Saturated Fatty Acids** are found chiefly in animal sources such as meat and poultry, whole or reduced-fat milk, and butter. Some vegetable oils like coconut, palm kernel oil, and palm oil are saturated. Saturated fats are usually solid at room temperature.
- **Monounsaturated Fatty Acids** are found mainly in vegetable oils such as canola, olive, and peanut oils. They are liquid at room temperature.
- **Polyunsaturated Fatty Acids** are found mainly in vegetable oils such as safflower, sunflower, corn, flaxseed, and canola oils. Polyunsaturated fats are also the main fats found in seafood. They are liquid or soft at room temperature. Specific polyunsaturated fatty acids, such as linoleic acid and alpha-linolenic acid, are called essential fatty acids. They are necessary for cell structure and making hormones. Essential fatty acids must be obtained from foods we choose.
- **Trans–Fatty Acids** are formed when vegetable oils are processed into margarine or shortening. Sources of trans-fats in the diet include snack foods and baked goods made with "partially hydrogenated vegetable oil" or "vegetable shortening." Trans–fatty acids also occur naturally in some animal products such as dairy products.

Cholesterol Is Different

Blood (serum) cholesterol and dietary cholesterol are two different types of cholesterol. Dietary cholesterol is found in food of animal origin such as egg yolks, organ meats, and full-fat dairy products. Blood cholesterol is a waxy substance that occurs naturally in our body. It is used to make estrogen and testosterone, and bile, which is needed for digestion. However, if the level of cholesterol in the blood is too high, cholesterol and other fats can stick to the artery walls.

Because blood cholesterol is waxy and cannot dissolve in water, it is carried through the blood in packages called lipoproteins. High-density lipoprotein (HDL) is a "good" package for cholesterol and low-density lipoprotein (LDL) is a "bad" package for cholesterol.

HDL cholesterol collects excess cholesterol in the blood and carries it to the liver. The liver reprocesses or excretes it. HDL may also help remove some of the cholesterol deposited on the artery walls.

Excess LDL cholesterol can increase the risk of heart disease because it is LDL cholesterol that accumulates on the artery walls. The type of fats and oils we eat helps control LDL levels.

Fat and Cholesterol: Know Your Limits

The guidelines for fat intake are well known: for healthy Americans, consume no more than 30% of total calories from fat. The "30 percent" guideline means:

- 7%-10% of total calories from saturated fats
- About 10%-15% of total calories from monounsaturated fats
- About 10% of total calories from polyunsaturated fats

Healthy Americans should limit their cholesterol intake to less than 300 milligrams per day.

From Duyff RL: *American Dietetic Association complete food and nutrition guide*, ed 3, Hoboken, New Jersey, 2006, John Wiley & Sons.

Proteins can be used as a source of energy but should be spared for their more important role in body health by the sufficient intake of carbohydrates.

Vitamins are organic substances that are present in minute amounts in foods. Because vitamins are crucial for metabolism and cannot be made in adequate amounts by the body, they must be gained through food or vitamin supplements. (An ample intake of vitamins through a balanced diet should make vitamin supplements unnecessary in healthy people.) Vitamins are water soluble or fat soluble. Vitamins C and B complex contain eight water-soluble vitamins. Water-soluble vitamins cannot be stored in the body. They must come from the daily diet. Fat-soluble vitamins (vitamins A, D, E, and K) can be stored in the body. Therefore a daily dietary intake of these vitamins is not required (Box 2-2).

Minerals are inorganic elements that play a key role in biochemical reactions in the body. These minerals include calcium, chromium, iron, magnesium, potassium, selenium, sodium, and zinc. Like vitamins, minerals come from the diet (Table 2-1).

Water is the most important nutrient because cellular function depends on a fluid environment. Water composes 50% to 60% of the total body weight. (Infants have the greatest percentage of body water; older adults have the least.) Water is obtained through consumption of liquids and fresh fruits and vegetables. Water is also produced when food is oxidized during digestion.

BOX 2-2 Free Radicals and Antioxidants

Free radicals are natural by-products of chemical reactions in the body that can produce cellular injury. The buildup of these free radicals increases with age. The buildup is thought to be the cause of many diseases, including heart disease, diabetes, and some cancers. Substances that can generate free radicals can be found in fried foods, alcohol, tobacco smoke, pesticides, and air pollution. Other substances to which persons often are exposed also may create free radicals.

Antioxidants are known as free radical scavengers. They are compounds that reduce the formation of free radicals or react with and neutralize them, making them nontoxic to cells. Antioxidants occur naturally in the body. They also occur naturally in certain foods such as fruits, vegetables, and whole grains. Beta carotene (a form of vitamin A) and vitamins C and E are popular antioxidant supplements. These may benefit a person's health.

TABLE 2-1 The ABCs of Nutrition

	Function	Source
Vitamins		
A	Proper eye function; keeps skin, hair, and nails healthy; helps maintain healthy gums, glands, bones, teeth; helps ward off infection; may protect against lung cancer	Liver,* dairy products,* fish, carrots, yellow squash, dark-green leafy vegetables, corn, tomatoes, papaya
B_1 (thiamine)	Helps convert carbohydrates into biological energy; promotes proper nerve function	Pork,* unrefined and enriched cereals, organ meats,* legumes, nuts*
B_2 (riboflavin)	Crucial in the production of body energy	Milk,* cheese,* yogurt,* green leafy vegetables, fruits, bread, cereals, meats*
B_3 (niacin)	Lowers cholesterol levels in blood only in very high doses; may protect against cardiovascular disease	Yeast, meats* including liver,* cereals, legumes, seeds*
B_6	Essential for protein breakdown and absorption	Beef,* poultry,* fish, pork,* bananas, nuts,* whole grains, vegetables
B_{12}	Essential for the healthy function of nerve tissue	Meats,* meat products,* shellfish, fish, poultry,* eggs*
Biotin	Needed for breakdown of glucose (a type of sugar) and formation of certain fatty acids necessary for several important body functions	Meats,* poultry,* fish, eggs,* nuts,* seeds,* legumes, vegetables
C (ascorbic acid)	Strengthens blood vessel walls; keeps gums healthy; promotes healing of cuts and wounds	Strawberries, citrus fruits, tomatoes, cabbage, cauliflower, broccoli, greens
D	Helps build and maintain teeth and bones; needed for body to absorb calcium	Egg yolks,* fish and cod liver oil,* fortified milk and butter*
E	Helps form red blood cells, muscle tissue, and other tissues; may protect against heart disease	Poultry,* seafood, seeds,* nuts,* cooked greens, wheat germ, fortified cereals, eggs*
K†	Needed for normal clotting of blood	Spinach, broccoli, brussels sprouts, kale, turnip greens
Minerals		
Calcium	Helps build strong bones and teeth; promotes proper muscle and nerve function; helps blood to clot; helps activate enzymes needed to convert food to energy; may protect against the development of fragile, porous bones	Milk,* cheese,* yogurt,* buttermilk, other dairy products,* green leafy vegetables†
Chromium	Works with insulin to maintain normal blood glucose	Whole-grain cereals, condiments (black pepper, thyme), meat products,* cheeses*
Iron	Essential to make hemoglobin, the oxygen-carrying component of red blood cells	Red meat* and liver,* shellfish and fish, legumes, dried apricots, fortified breads and cereals
Magnesium	Activates enzymes needed to release energy in body; promotes bone growth; needed to make cells and genetic material	Green leafy vegetables, beans, nuts,* fortified wholegrain cereals and breads, oysters, scallops
Potassium	With sodium, helps to regulate body's fluid balance; plays a major role in muscle contraction, nerve conduction, beating of the heart	Bananas, citrus fruits, dried fruits, deep yellow vegetables, potatoes, legumes, milk,* bran cereal
Selenium	Interacts with vitamin E to prevent breakdown of cells in body	Organ meats,* seafood, meats,* cereals and grains, egg yolks,* mushrooms, onions, garlic
Sodium	Helps maintain body fluid balance	Salt, processed foods, foods in brine, salted crackers and chips, cured meats, soy sauce (Note: sodium is so prevalent that low intake is very rare. The problem is avoiding excessive intake of sodium.)
Zinc	Boosts the immune system and helps fight disease; element in more than 100 enzymes—proteins that are essential to digestion and other functions	Red meats,* some seafoods, grains

From U.S. Department of Agriculture's Center for Nutrition Policy and Promotion, Washington, DC, accessed at www.usda.gov.
*These foods are high in fat and/or cholesterol. Use sparingly or substitute low-fat versions, where possible.
†Green leafy vegetables and other foods rich in vitamin K can contribute to blood clotting. If you take a drug that prevents blood clotting, talk to your physician before changing your diet.

NOTE
Diseases caused by vitamin deficiency (e.g., *scurvy, rickets,* or *beriberi*) are rare in the United States. Making proper food choices can help to prevent them.

DIETARY RECOMMENDATIONS

Various health care groups make recommendations for a healthful diet. These groups include the U.S. Department of Agriculture (USDA), the U.S. Department of Health and Human Services, and the Food and Drug Administration. Box 2-3 lists the nutritional recommended intake values and Table 2-2 and Box 2-4 give the dietary recommendations for the general population as recommended by the American Heart Association, the National Institutes of Health, and the USDA.

CRITICAL THINKING
Does your average diet meet these guidelines? If not, in what areas do you need to make changes?

FOOD GUIDANCE PYRAMID

In 2005, the USDA revised and simplified the original food guide pyramid, established in 1992. The food pyramid is known as MyPyramid. It was designed to educate the public and health professionals about diet and lifestyle that was consistent with the *2005 Dietary Guidelines for Americans* (revised in 2010).[1]

BOX 2-3 Nutritional Components of the TLC Diet

Nutrient	Recommended Intake
Saturated fat*	<7% of total calories
Polyunsaturated fat	Up to 10% of total calories
Monounsaturated fat	Up to 20% of total calories
Total fat	25%-35% of total calories
Carbohydrate (esp. complex carbs)	50%-60% of total calories
Fiber	20-30 g/day
Protein	~15% of total calories
Cholesterol	<200 mg/day

TABLE 2-2 Summary of Diet and Lifestyle Recommendations from the American Heart Association Nutrition Committee 2006

Population Goals	Major Guidelines
Consume an overall healthy diet	Consume a variety of fruits, vegetables, and grain products, especially whole grains; choose fat-free and low-fat dairy products, legumes, poultry, and lean meats; and eat fish, preferably oily fish, at least twice a week.
Aim for a healthy body weight BMI 18.5-24.9 kg/m^2	Achieve and maintain healthy weight throughout life with increased effort aimed at helping individuals avoid inappropriate weight gain during childhood years and subsequent weight gain during adult years. Increase emphasis on prevention of weight gain in the first place.
Aim for a desirable lipid profile LDL-C <100 mg/dL optimal 100-129 mg/dL near or above optimal 130-159 mg/dL borderline high 160-189 mg/dL high ≥190 mg/dL very high TG <150 mg/dL HDL-C >40 mg/dL (men) >50 mg/dL (women)	Reduce daily intake of saturated fat (<7%), trans-fat (<1%), and cholesterol (300 mg). Avoid excess body weight. Drug therapy is often prescribed for those at moderate or high risk. Dietary changes are recommended for all individuals.
Aim for a normal BP Systolic BP <120 mm Hg Diastolic BP <80 mm Hg	Reduce salt intake; induce weight loss by caloric deficit, moderation of alcohol (among those who drink), increased potassium intake. Stress consumption of a healthy diet such as the DASH diet that emphasizes fruits and vegetables and low-fat dairy. Include whole grains, poultry, fish, and nuts. Reduce fat, red meat, sweets, and sugar-containing beverages. Replace some carbohydrates either with protein from plant sources or with monounsaturated fat.
Be physically active	All adults should accumulate ≥30 minutes of physical activity most days of the week. At least 60 minutes of physical activity most days of the week is recommended for children and those adults attempting to lose weight or maintaining weight loss.
Avoid use and exposure to tobacco products	Eliminate the use of tobacco products and minimize exposure to second-hand smoke.

From Lichtenstein AH, Appel LJ, Brands M, et al: Diet and lifestyle recommendations revision 2006: a scientific statement from the American Heart Association Nutrition Committee, *Circulation* 114:82-96, 2006.

BOX 2-4 USDA Dietary Guidelines for Americans: Key Recommendations

Balancing Calories to Manage Weight

- Prevent and/or reduce overweight and obesity through improved eating and physical activity behaviors
- Control total calorie intake to manage body weight. For people who are overweight or obese, this will mean consuming fewer calories from foods and beverages
- Increase physical activity and reduce time spent in sedentary behaviors
- Maintain appropriate calorie balance during each stage of life—childhood, adolescence, adulthood, pregnancy and breastfeeding, and older age

Foods and Food Components to Reduce

- Reduce daily sodium intake to fewer than 2300 milligrams (mg) and further reduce intake to 1500 mg among persons who are 51 and older and those of any age who are African-American or have hypertension, diabetes, or chronic kidney disease. The 1500-mg recommendation applies to about half of the U.S. population, including children, and the majority of adults
- Consume fewer than 10% of calories from saturated fatty acids by replacing them with monounsaturated and polyunsaturated fatty acids
- Consume fewer than 300 mg per day of dietary cholesterol
- Keep trans fatty acid consumption as low as possible by limiting foods that contain synthetic sources of trans fats, such as partially hydrogenated oils, and by limiting other solid fats
- Reduce the intake of calories from solid fats and added sugars
- Limit the consumption of foods that contain refined grains, especially refined grain foods that contain solid fats, added sugars, and sodium
- If alcohol is consumed, it should be consumed in moderation—up to one drink per day for women and two drinks per day for men—and only by adults of legal drinking age

Foods and Nutrients to Increase

Individuals should meet the following recommendations as part of a healthy eating pattern while staying within their calorie needs

- Increase vegetable and fruit intake
- Eat a variety of vegetables, especially dark green and red and orange vegetables and beans and peas
- Consume at least half of all grains as whole grains. Increase whole-grain intake by replacing refined grains with whole grains
- Increase intake of fat-free or low-fat milk and milk products, such as milk, yogurt, cheese, or fortified soy beverages*
- Choose a variety of protein foods, which include seafood, lean meat and poultry, eggs, beans and peas, soy products, and unsalted nuts and seeds
- Increase the amount and variety of seafood consumed by choosing seafood in place of some meat and poultry
- Replace protein foods that are higher in solid fats with choices that are lower in solid fats and calories and/or sources of oils
- Use oils to replace solid fats when possible
- Choose foods that provide more potassium, dietary fiber, calcium, and vitamin D, which are nutrients of concern in American diets. These foods include vegetables, fruits, whole grains, and milk and milk products

Recommendations for Specific Population Groups

Women Capable of Becoming Pregnant?†

- Choose foods that supply heme iron, which is more readily absorbed by the body, additional iron sources, and enhancers of iron absorption such as vitamin C-rich foods
- Consume 400 micrograms (mcg) per day of synthetic folic acid (from fortified foods and/or supplements) in addition to food forms of folate form a varied diet‡

Women Who Are Pregnant of Breastfeeding?

- Consume 8 to 12 ounces of seafood per week from a variety of seafood types
- Due to their high methyl mercury content, limit white (albacore) tuna to 6 ounces per week and do not eat the following four types of fish: tilefish, shark, swordfish, and king mackerel
- If pregnant, take an iron supplement as recommended by an obstetrician or other health care provider

Individuals Age 50 Years and Older

- Consume foods fortified with vitamin B_{12}, such as fortified cereals or dietary supplements

Building Health Eating Patterns

- Select an eating pattern that meets nutrient needs over time at an appropriate calorie level
- Account for all foods and beverages consumed and assess how they fit within a total healthy eating pattern
- Follow food safety recommendations when preparing and eating foods to reduce the risk of foodborne illnesses

*Fortified soy beverages have been marketed as "*soymilk,*" a product name consumers could see in supermarkets and consumer materials. However, the FDA's regulations do not contain provisions for the use of the term soymilk. Therefore, in this document, the term *fortified soy beverage* includes products that may be marketed as soymilk.

†Includes adolescent girls.

‡Folic acid is the synthetic form of the nutrient, whereas folate is the form found naturally in foods.

NOTE
In 2011, the MyPlate image was introduced for the consumer. MyPlate is a visual place setting that is intended to simplify eating recommendations for the general public, using five food groups: grains, vegetables, fruits, dairy, and protein.

MyPyramid has 12 sets of possible recommendations based on age, gender, and activity level. The new pyramid stresses activity and moderation along with the proper mix of food groups in a person's diet (Fig. 2-1). MyPyramid contains five food groups. They are:

1. Grains, recommending that half or more of grains be eaten as whole grains

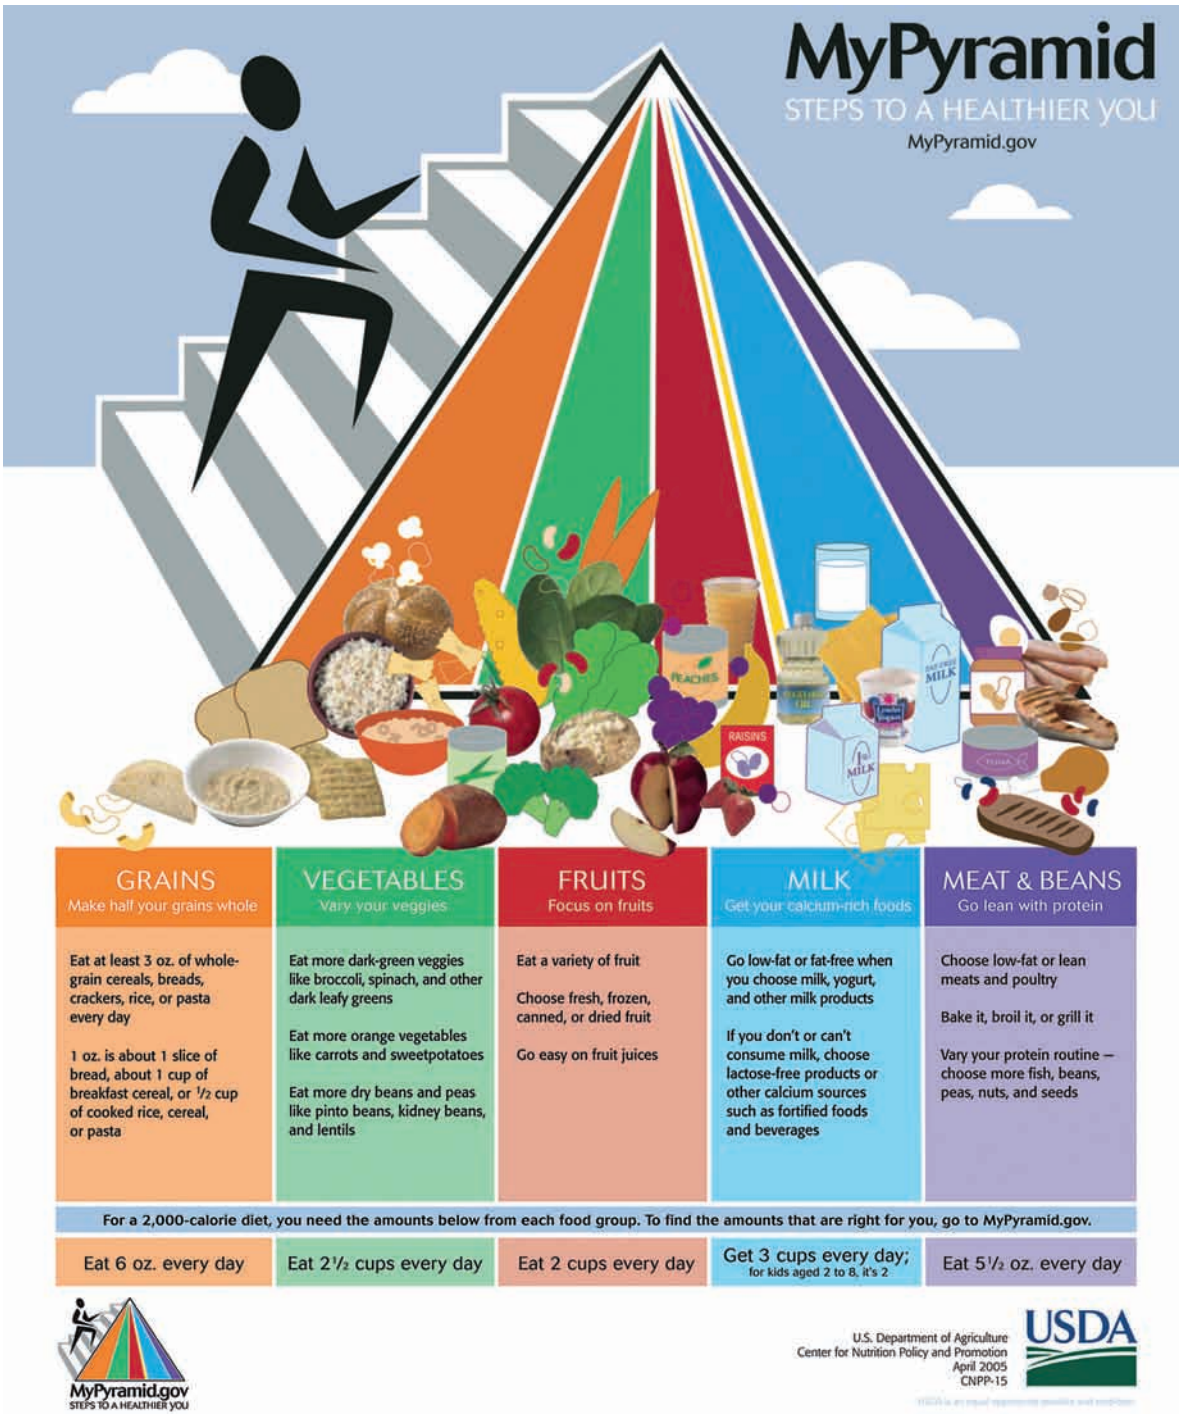

FIGURE 2-1 MyPyramid. (From Nix S: *William's basic nutrition & diet therapy*, ed 13, St Louis, 2009, Mosby.)

2. Vegetables, emphasizing dark green vegetables, orange vegetables, and dry beans and peas
3. Fruits, emphasizing variety, deemphasizing fruit juices
4. Milk, including milk-based foods
5. Meat and beans (proteins), emphasizing low-fat and lean meats as well as peas, nuts, and seeds

Two other categories of the MyPyramid are physical activity and discretionary calories. Physical activity is shown in the figure by a person climbing steps. Discretionary calories are those from candy, alcohol, and other foods. These calories are shown in the figure by the narrowed tip of each colored band. The slogan in the figure "Steps to a Healthier You" is to remind people that they can benefit from small steps to improve their diet and lifestyle.

Principles of Weight Control. Persons who are overweight tend to be at higher risk for developing certain illnesses. These illnesses include high blood pressure, diabetes mellitus, heart disease, and some cancers. The tenets of weight control are to eat the right balance of foods in moderation, limit fat consumption, and exercise regularly (Box 2-5).

Anyone committed to weight control for a healthier life should set realistic goals. For example, the general recommendation is a steady weight loss goal of 1/2 to 1 lb per week. (3500 calories is equal to 1 pound. An extra 500 calories per day results in a 1 pound gain per week; 500 fewer calories per day results in a 1 pound loss per week.) A healthful lifestyle is balanced with proper nutrition and exercise. A healthful diet includes a variety of foods that are low in fat, saturated fat, and cholesterol. A healthful diet also includes plenty of grain products, vegetables, and fruit (Box 2-6). A diet should also contain modest amounts of simple sugars, salt, and sodium. Alcoholic beverages should be avoided or consumed only in moderation. Finally, a system for checking weight control progress is essential. Adjustments and professional advice sometimes may be needed to achieve weight control goals.

BOX 2-5 Getting a Handle on Fat

Eat foods that are less than 30% fat. Try to aim for no more than 3 g of fat per 100 calories, which provides about 27% of the total calories from fat. This is important for the following reasons:

- Each gram of fat has more than double the calories of a gram of protein or carbohydrates.
- The body uses fewer calories to store the fat as excess weight.
- In complex carbohydrates, 23% of the calories are burned to make them into a usable form in the body; only 3% of fat calories are burned before they are "worn" on the hips or abdomen.
- Decreasing fat intake to less than 30% of daily calories helps reduce cholesterol, decreases risk of heart disease, helps with weight loss, and reduces risk of diabetes.

Fat Content of Various Foods

More than 90% fat: whipped cream, pork sausage, cooking oils, margarine, butter, gravy, mayonnaise

More than 80% fat: spare ribs, bologna, cream cheese, salad dressing, high-fat steaks (T-bone, porterhouse, tenderloin, filet mignon)

More than 70% fat: Half and Half dairy creamer, peanuts, hot dogs, pork chops, most cheeses and nuts, sirloin steak, bacon, lamb chops

More than 60% fat: potato and corn chips, regular ground beef, ham, eggs

More than 50% fat: round steak, pot roast, creamed soup, ice cream, sweet rolls

More than 40% fat: whole milk, cake, doughnuts, french fries

More than 30% fat: muffins, cookies, fruit pies, low-fat milk, cottage cheese, tuna, chicken, turkey

More than 20% fat: lean fish, beef liver, ice milk

More than 10% fat: bread, pretzels, whole grains, legumes

Less than 10% fat: sherbet, nonfat milk, most fruits and vegetables, baked potato

DID YOU KNOW?

Food Labels 101

Understanding food labels and food content is important for a healthy diet. To help you make healthy choices in food, follow these steps when reading food labels (Figure 2-2):

Step 1: Look at the serving size and the number of servings per container or package. The sample here shows 2 servings (2 cups) in the package. If you eat the entire package of macaroni and cheese, you double your calories and other nutrients, including your percentage of daily allowance values (%DVs). A general rule for %DVs is 5% or less is low; 20% or more is high.

Step 2: Check the calories and note how many of those calories come from fat. In the figure, the fat calories per serving are 250, and 110 of those calories are from fat. If you eat the whole package, you will consume 500 calories and 220 of those will come from fat. The general rule for calories is 40 is low, 100 is moderate, 400 or more is high.

Steps 3 and 4: Look at the nutrients on the label. The ones in yellow should be limited. Eating too much fat, saturated fats, trans-fats, cholesterol, or sodium can increase your risk of certain chronic diseases. The nutrients in blue are good for you. They can improve your health and may reduce the risk of some diseases and conditions.

Step 5: Read the footnote on the bottom of the Nutrition Facts label. This tells you that the %DVs are based on a 2000 calorie diet. This is the recommended dietary advice for all Americans. It does not change from package to package.[2]

PHYSICAL FITNESS

Physical fitness can be described as a condition that helps persons look, feel, and do their best (Figure 2-3). Physical fitness is individual and varies from person to person. Physical fitness also is influenced by age, gender, heredity, personal habits, exercise, and eating habits. Being physically fit offers many benefits, which include the following:

- Decreased resting heart rate and blood pressure
- Increased oxygen-carrying capacity

BOX 2-6 Fiber

The human body requires fiber to maintain good health and to fight disease. Fiber (found only in plant foods) may be soluble or insoluble. Examples of soluble fiber include fiber obtained from peas, beans, oats, barley, and some fruits and vegetables. This type of fiber helps control the level of blood glucose. Soluble fiber also may lower the level of blood cholesterol. Insoluble fiber (found in whole grains and many vegetables) helps hold water in the colon and can reduce or prevent constipation. This type of fiber also may help prevent intestinal disease (e.g., diverticulosis, hemorrhoids, and certain cancers). Many authorities recommend a dietary intake of 20 to 35 g of fiber each day.

Dietary Fiber		25 g	30 g

⑥ Quick guide to % Daily Value

- 5% or less is low
- 20% or more is high

FIGURE 2-2 Food labels. (From Mahan LK, Stump S: *Krause's Food and nutrition therapy,* ed 12, St Louis, 2008, WB Saunders.)

NOTE

Many food labels list calorie-containing nutrients in grams. The paramedic should know how to convert the grams to calories to avoid weight gain. Carbohydrates and proteins have 4 calories per gram. Fats have 9 calories per gram. (Vitamins, minerals, and water have no calories.) It is not the grams that lead to weight gain—it is the excess calories found in grams. Because fats contain more than double the amount of calories per gram than carbohydrates and proteins, a food item can have less *grams* of fat, but still have more *calories* from fat.

- Enhanced quality of life
- Increased muscle mass and metabolism
- Increased resistance to injury
- Improved personal appearance and self-image
- Maintenance of motor skills throughout life

Cardiovascular Endurance. A physical examination is the first step before starting a fitness program. Another step is to have a fitness assessment performed by a certified physical trainer. The purpose of these assessments is to evaluate a person's present physical condition. These exams also create baseline assessments for weight, including body mass index (Box 2-7); high blood pressure; heart disease (including family history); arthritis or other bone problems; muscular, ligament, or tendon problems; and other known or suspected diseases. These assessments help to establish a heart rate target zone as well. This is a measure used to improve cardiovascular endurance through exercise. Ideally, the heart rate target zone should be maintained during exercise for 20 minutes to increase cardiovascular endurance.

Muscle Strength. Another part of the fitness assessment tests muscular strength and endurance. Muscular strength is the ability of a muscle to exert force for a brief period. Muscle endurance is the ability of a muscle or a group of muscles to sustain repeated contractions or to continue applying force against a fixed object. Many exercises improve muscle strength and endurance.

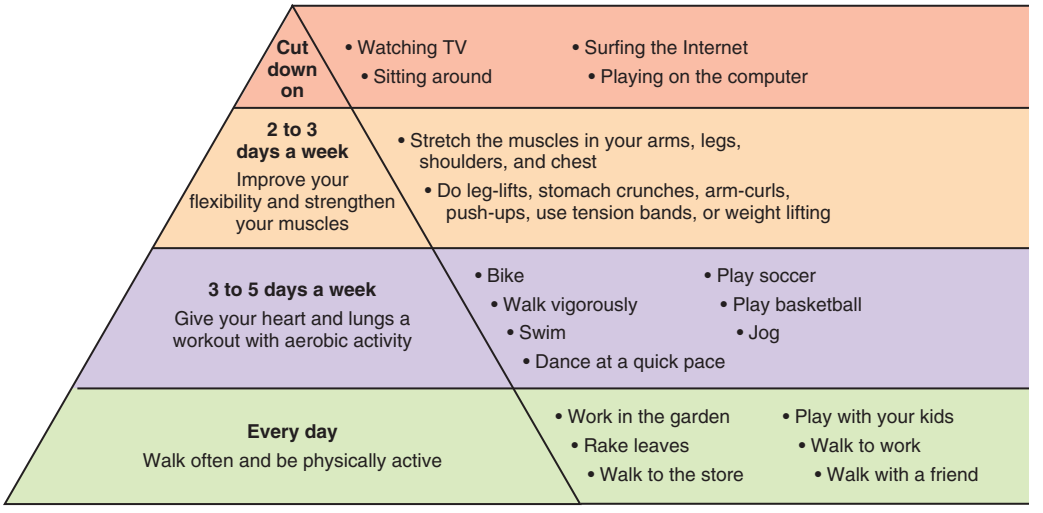

FIGURE 2-3 Exercise pyramid.

BOX 2-7 The Body Mass Index

The body mass index (BMI) is a widely used measurement of body fat that corrects for height. The BMI is the only body fat index that conveys the risk of disease or death. A healthful BMI is 19 to 25. A BMI of 25 to 29 indicates "moderately overweight." A BMI of 30 or more indicates "severely overweight." To calculate your body mass index, use the following formula:

Step 1: Multiply your weight in pounds by 0.45.
Example: 150 pounds × 0.45 = 67.5

Step 2: Multiply your height in inches by 0.025.
Example: 5 ft 9 in, or 69 inches × 0.025 = 1.725

Step 3: Square the answer from step 2.
Example: 1.725 × 1.725 = 2.976

Step 4: Divide the answer in step 1 by the answer in step 3.
Example: 67.5 ÷ 2.976 = BMI of 22.7

SHOW ME THE EVIDENCE

EMS personnel re-registering with the NREMT were surveyed to determine their body mass index (BMI). The mean BMI for study participants was 27.74 (95% CI 27.68-27.81), and 71.5% of participants were classified as having high (greater than or equal to 25) BMI. More males reported having a high BMI compared to females (79.2% vs 50.8%, respectively, $p < 0.001$). More paramedics reported the higher BMI than any of the other levels of licensure. Military EMS personnel reported the lowest prevalence of high BMI (61.7%). Fire-based EMS personnel had the highest (77.7%).

From Fernandez AR, Studnek JR: *Body mass index of emergency medical services professionals,* Poster presentation at 2008 annual meeting of the National Association of EMS Physicians, Phoenix.

CRITICAL THINKING

Calculate your body mass index. Does it fall within the recommendations?

NOTE

There is a simple way to determine the heart rate target zone. First, multiply the established maximum heart rate of 220 minus a person's age in years. Then multiply this number by 70%.

Example for a 25-year-old:

$$\text{Maximum heart rate } (220 - 25) = 195$$

$$195 \times 70\% = 136 \text{ beats/min}$$

The tenets of training for muscle strength and endurance should consider isometric and isotonic exercises, resistance, repetitions, sets, and frequency. *Isometric* exercises are those that do not result in any movement of a joint. An example of this is a contraction performed against an immovable object such as a wall or door frame. These exercises do not significantly increase muscle bulk, but they do strengthen the muscle at the joint angle at which the contraction is performed. *Isotonic* exercises move a joint through a range of motion against resistance of a fixed weight. An example of this is lifting a barbell. These exercises add muscle bulk by creating tension within the muscle. *Resistance* refers to the amount of weight moved or lifted during isotonic exercises. A *repetition* ("rep") refers to the full execution of an exercise from start to finish. A *set* is the number of times an exercise (rep) is done from start to finish, one after another, without any rest time. *Frequency* refers to the least number of workouts that will have a positive effect on muscle strength and endurance.

Muscular Flexibility. Flexibility refers to the ability to move joints and use muscles through their full range of motion. The fitness assessment tests flexibility in several ways. A lack of normal flexibility may lead to muscle strains and other injuries.

Muscular flexibility can be improved by stretching exercises. These exercises must be done slowly, without a bouncing motion. The intensity of these exercises should be mild. A person should not strain or hold the breath and should feel no pain or discomfort. How often these exercises are done should match an individual's specific level of activity. For example, if daily work on an ambulance requires lifting patients, then regular stretching exercises specific to the paramedic's arms, back, thighs, calves, and hips would be helpful.

CRITICAL THINKING

How many minutes per week do you perform physical activities that raise your heart rate? What benefits does a paramedic gain by maintaining a high level of personal fitness?

THE IMPORTANCE OF SLEEP

Sleep plays an important role in being physically fit because it helps to rejuvenate a tired body. The average adult needs 7 to 8 hours of sleep each day. In emergency medical services (EMS), where rotating shifts and 24- and 48-hour work shifts are common, sleep deprivation may occur and interrupt the normal circadian rhythm.

Circadian is Latin for "about a day." The circadian rhythm is the physiological ebb and flow of the body as it relates to the rotation of the earth. This timing system is based roughly on the solar day as the earth rotates in its course around the sun. For example, a person gets hungry or tired, or energetic or moody, at fairly set times each day as the body systems change. The levels of melatonin and cortisol affect the periods of sleepiness and wakefulness, respectively. As will be discussed in Chapter 10, the pineal gland secretes melatonin. The adrenal glands secrete cortisol. Release of these hormones is stimulated by the dark and is suppressed by light. Thus when the line between night and day is disrupted on an ongoing basis (e.g., working rotating work shifts or responding to emergency calls in the early morning hours during a 24- or 48-hour shift), irritability, depression, and illness can result (Box 2-8).

BOX 2-8 Getting Your Z's

Working nights, 24- and 48-hour shifts, and rotating shifts can prevent you from getting enough rest. The following are some helpful tips:

- Allow some time to unwind and relax before trying to go to sleep.
- Consider exercise before sleeping as a way to reduce stress.
- Avoid stimulants (e.g., caffeine in coffee, soda, tea, and chocolate) during the last few hours of your work shift.
- Eat simple carbohydrates (e.g., cookies or candy bar) to release serotonin (a hormone that may help induce sleep).
- Keep your sleeping area cool and dark so that your body will think it is nighttime.
- Make sure your family and friends know about your work shifts and your sleeping schedule to minimize interruptions.
- Try to maintain a "normal" period of dedicated sleep time each day.
- Consult a physician about your sleep difficulties when needed.

SHOW ME THE EVIDENCE

A preliminary study published in *The Lancet Oncology*[3] provides a summary of scientific evidence of increased cancer risk in night-shift workers, as well as increased cancer risk in painters and firefighters. The study, conducted by the World Health Organization's International Agency for Research on Cancer (IARC), emphasizes the impact of night-shift work on melatonin secretion, immune function, cancer risk, and disruption of circadian rhythm. More information about this study can be found at: www.epidemiologic.org/2007/12/iarc-cancer-hazards-associated-with.html, accessed 1-28-09. IARC: Cancer hazards associated with shiftwork, painting, and firefighting.

Shift-work studies have been done by numerous agencies, including the Centers for Disease Control and Prevention and the National Institute for Occupational Safety and Health.[4] Findings in these studies suggest sleep loss:

- Makes it easier to fall asleep at inappropriate times
- Affects performance both on and off the job
- Can lead to serious injuries
- Disrupts social and family life
- Increases health risks for digestive problems and heart disease

Other studies have shown that people who have disruptions in their circadian rhythms because of extended work shifts have increased risks of motor vehicle crashes, short-term decreases in cognition and neuropsychological performance, decreased job satisfaction, and an increased likelihood for making errors that result in patient care litigation.[5,6] Research and work shift studies are still underway. The goals of these are to help shift workers and their employers modify work schedules so that changes in normal biorhythms will have the least adverse effects on employee health and productivity.

CRITICAL THINKING

Do you get enough sleep? If not, which of these strategies should you try in an attempt to increase your hours of sleep?

DISEASE PREVENTION

There are many things a paramedic can do to help prevent serious personal illness. As health care professionals, paramedics must serve as role models in helping to prevent disease.

Cardiovascular Disease. Cardiovascular disease accounts for more than 830,000 deaths each year in the United States.[7] For most persons, cardiovascular disease can be altered through living a healthful life. Boosting cardiovascular endurance can help to prevent this disease. However, other steps are also needed. These steps include the following:

- Eliminating cigarette smoking
- Controlling high blood pressure
- Maintaining a favorable body fat composition through regular exercise
- Maintaining a good total cholesterol/high-density lipoprotein ratio (Box 2-9)
- Monitoring triglyceride levels
- Controlling diabetes
- Avoiding excessive alcohol intake
- Eating healthful foods
- Reducing stress
- Obtaining risk assessments periodically

Cancer. The term *cancer* includes more than 100 diseases affecting nearly every part of the body. All these diseases are potentially life threatening. The main cause of all cancer is a change or mutation in the nucleus of a cell. Most common cancers are linked to one of three environmental risk factors: smoking, sunlight, or diet. Dietary factors are associated with some cancers of the gastrointestinal tract and may be linked to others, such as cancer of the breast, prostate, or uterus. Steps in preventing cancer include the following:

- Elimination of smoking
- Dietary changes
- Limitation of sun exposure; use of sunscreen
- Regular physical examinations
- Attention to the warning signs (Box 2-10)
- Periodic risk assessment

Infectious Disease. Most infectious diseases can be avoided by practicing good personal hygiene (including performing hand washing and following **universal precautions** and other guidelines in the workplace). These guidelines are established by the Centers for Disease Control and Prevention, the Occupational Safety and Health

BOX 2-9 Understanding the Cholesterol Numbers

Cholesterol moves through the body attached to various sizes of fat-carrying proteins. These proteins are called lipoproteins. Low-density lipoproteins (LDLs) are more common. They are thought to carry cholesterol to the cells and to promote blood vessel disease. Smaller high-density lipoproteins (HDLs) are thought to carry cholesterol to the liver. They may help prevent or slow down blood vessel disease. Very-low-density lipoproteins are made mostly of triglycerides (the main fatty substance in the fluid portion of blood) that are absorbed by the intestines and therefore are affected by fasting. (Fasting is abstaining from all or certain foods.)

Cholesterol

High blood cholesterol: 240 mg/dL or higher
Borderline high blood cholesterol: 220 to 239 mg/dL
Desirable blood cholesterol: less than 200 mg/dL

LDL Cholesterol: The "Bad or Lousy" Cholesterol

Very high LDL cholesterol: 189 mg/dL or higher
High LDL cholesterol: 160 to 189 mg/dL or higher
Borderline high LDL cholesterol: 130 to 159 mg/dL
Desirable LDL cholesterol in healthy persons: less than 100 mg/dL
Desirable LDL cholesterol in persons at risk for heart disease: less than 90 mg/dL

HDL Cholesterol: Higher Is Better

Low HDL cholesterol: less than 40 mg/dL
Desirable HDL cholesterol: greater than 60 mg/dL

Very-Low-Density Lipoproteins/Triglyceride: Lower Is Better

Should not exceed 200 to 300 mg/dL

BOX 2-10 The Seven Warning Signs of Cancer (CAUTION) as Designated by the American Cancer Society

*C*hange in bowel or bladder habits
A sore throat that does not heal
*U*nusual bleeding or discharge
*T*hickening or lump in the breast or elsewhere
*I*ndigestion or difficulty swallowing
*O*bvious change in a wart or mole
*N*agging cough or hoarseness

Administration, the National Fire Protection Association, the Federal Emergency Management Agency, the United States Fire Administration, and others (Table 2-3). Universal precautions and other personal safety measures will be discussed throughout this text.

TABLE 2-3 Personal Equipment for Protection Against Transmission of HIV and Hepatitis B Virus

Activity	Disposable Gloves	Gown	Mask	Protective Eyewear
Bleeding control (spurting blood)	Yes	Yes	Yes	Yes
Bleeding control (minimal blood)	Yes	No	No	No
Emergency childbirth	Yes	Yes	Yes*	Yes*
Intravenous therapy	Yes	No	No	No
Endotracheal intubation	Yes	No	Yes*	Yes*
Oral or nasal suctioning	Yes	No	No	No
Administration of an injection	No	No	No	No

*If splashing is likely.

DID YOU KNOW?

The Right Way to Wash Your Hands

The most important tool in your arsenal for preventing infection and protecting yourself from illness is washing your hands. Hand washing should be done whenever your hands are soiled. Hand washing should also be done between each patient contact, before eating, after using the restroom, and after coughing, sneezing, or blowing your nose. The CDC recommends vigorous scrubbing with warm soapy water for at least 15 seconds (or the time it takes to sing a short tune, such as Happy Birthday).

There are five easy steps to proper hand washing:

1. **Wet** your hands under warm running water; apply soap.
2. **Rub** your hands with soap under warm running water.
3. **Scrub** your hands for a count of at least 15 seconds. Scrub all surfaces, including the back of your hands, and wrists. Clean between your fingers and under your fingernails.
4. **Rinse** your hands under clean warm water.
5. **Dry** your hands on a paper towel or with an air dryer and use a towel to turn off the faucet.

When soap and water are not available, alcohol-based disposable hand wipes or gel sanitizers may be used. Gel sanitizers that contain at least 60% alcohol are more effective in killing bacteria and viruses than hand washing[8] and most contain ingredients that help prevent skin dryness.

At a minimum, personal protective equipment to guard against the spread of infectious diseases should include the following:

- Disposable gloves when contact with blood or other body fluids is likely
- Masks and protective eyewear when blood splashing is likely to occur
- Gowns to protect clothing from spurting blood (e.g., during emergency childbirth)

- HEPA (high-efficiency particulate air) filter and N-95 respirators when tuberculosis is confirmed or suspected (see Chapters 24 and 28)

If a potential exposure to an infectious disease occurs, the paramedic should report it as soon as possible. The report should be made to the receiving hospital and to the proper designated officer in the local agency (see Chapter 28). To defend against such diseases, the Occupational Safety and Health Administration requires a periodic risk assessment be offered to staff. The risk assessment includes regular testing for diseases such as tuberculosis and monitoring of vaccinations for infectious diseases (e.g., hepatitis B).

INJURY PREVENTION

The number of injuries that occur on the job can be reduced. Knowledge of proper body mechanics during lifting and moving is helpful. Staying alert for hostile settings also is essential. A paramedic must prioritize personal safety during rescue situations. Finally, one must practice safe vehicle operations and use safety equipment and supplies.

Body Mechanics During Lifting and Moving. One in four EMS workers suffers a career-ending back injury within the first 4 years of employment, and back injury is the number one reason for leaving the EMS profession.[9] Almost one in two workers (47%) have sustained a back injury while performing EMS duties.[10]

Using proper body mechanics during lifting and moving is crucial. This helps avoid personal injury as well as injury to a partner or patient (Box 2-11). The paramedic should consider the following guidelines when lifting and moving patients or equipment:

- Only move a victim you can handle safely; get additional help if needed.
- Look where you are walking or crawling.
- Move forward rather than backward when possible.
- Take short steps, if walking.
- Bend at the hips and knees.
- Maintain the natural curvature of the spine when possible.
- Lift with the legs, not the back.
- Keep the load close to the body.
- Keep patient's body in line when moving.

NOTE

When preparing to lift, contract the abdominals by pulling in the abdominal wall (sucking the belly button to the spine). This is the core of the body. In addition, the abdominals help stabilize the back and help produce power and strength. Lift by extending through the hips and legs, not the back. ("Think with the hips" when lifting.) The body works from the center, out. The hips are part of the "core" and more centralized than the legs. Therefore extending through the hips first adds another muscle group. It also instantly provides greater strength and power for lifting. Incorporating the hips can also help prevent knee injuries.

BOX 2-11 Prevention and Rehabilitation of Low Back Pain

The back is a complex system of ligaments, muscles, bones, nerves, and intervertebral disks. All of these parts can be injured by improper lifting techniques. Emergency medical services workers are highly vulnerable to low back pain and injury. A common cause of low back pain and injury is lordosis (an inward curvature in the lumbar spine that is normally present to some degree). Abnormal curvature in this area can result from poor posture and from being overweight with associated weak abdominal muscles. Back injury can be prevented or lessened to a significant degree by being physically fit, performing regular stretching exercises, and following some general rules of lifting:

1. Know the weight (ask the patient's weight if you can, and add the weight of the equipment). Two persons should work together to lift objects that weigh more than 60 lb.
2. Know your physical ability and limitations.
3. Keep your back positioned with a normal curvature.
4. Use your legs and abdominal muscles to support the weight; use your back muscles to maintain balance.
5. Keep the weight close to your body.
6. Communicate clearly and frequently with your partner.

If back pain or injury occurs when lifting, pushing, pulling, or stretching, tell a supervisor as soon as possible. Treatment for back pain usually begins with rest and ice or cold packs to lessen swelling. Treatment also can include pain medicine and muscle relaxants. A rehabilitation program usually will follow the injury. Rehabilitation often includes exercises to improve abdominal muscle strength. The exercises also help to improve the control of the pelvis and the flexibility of the lower back.

From *EMT: injury free*, Wilmington, Ohio, 1991, Ferno-Washington.

Hostile Environments. As part of EMS work, paramedics may sometimes find themselves in hostile situations. Such situations may include responding to violent crimes of murder, rape, robbery, domestic violence, acts of terrorism, and aggravated assault. These crimes often are linked with the use of illegal drugs. This environment may threaten one's personal safety. When these situations occur, paramedics should do the following:

- Carefully check the scene for safety concerns and do not enter the scene until it is safe.
- Coordinate all actions with law enforcement personnel.
- Follow protocols for establishing medical incident command (see Chapter 54).
- Plan entrance and escape routes.
- Above all, stay alert and be prepared for the unexpected.

Safely managing a violent scene requires special training. The situation also calls for unity among many emergency response agencies. As members of the response team, paramedics should take part in planning, training, and practice sessions. These sessions help to ensure personal safety in hostile settings (see Chapter 58).

Rescue Situations. Many personal safety issues arise in the case of rescue. Examples include exposure to hazardous materials, bad weather, extremes in temperature, fire, toxic gases, unstable structures, heavy equipment, road hazards, and sharp edges and fragments. For every rescue response the key is to assess the scene for hazards first. One also must take personal protective measures. In addition, the scene should be monitored constantly during the operation. A safe rescue requires proper use of protective gear, special training, and safe rescue practices (see Chapter 55).

Safe Vehicle Operation. Safe operation of an emergency vehicle is important for personal safety and the safety of the crew and patient (see Chapter 53). Many factors affect safe vehicle operations, including the following:

- Safe driving of the vehicle
- Use of personal restraints for all occupants in the vehicle
- Safe and appropriate use of escorts to and from emergency scenes
- Adverse environmental conditions (e.g., inclement weather)
- Appropriate use of audible and visual warning devices
- Proceeding through intersections safely
- Parking at the emergency scene
  - Safe vehicle positioning strategies
- Maintaining due regard for the safety of all others

NOTE

Safe operations and personal safety on the roadways are of utmost importance. Emergency personnel should wear ANSII-2 reflective safety vests over turnout gear. They should also minimize the time they spend on roadways.

CRITICAL THINKING

Is there any patient situation that would call for using unsafe vehicle operations? Keep in mind that this could risk the safety of those in the ambulance or in other vehicles.

Some EMS agencies require their employees to take a specialized driver's training class. One such program is the U.S. Department of Transportation Emergency Vehicle Operation Course (EVOC). A program such as this allows EMS personnel to practice driving in a safe and controlled setting.

Safety Equipment and Supplies. Proper use of safety equipment and supplies is key to injury prevention for paramedics. Standards for protective clothing and equipment are required by the Occupational Safety and Health Administration. These and other standards (such as those set by the National Fire Protection Association) are used by many states, cities, and fire and EMS agencies to help ensure employee safety (see Chapter 54). Safety equipment and supplies include the following:

- Body substance isolation equipment
- Head protection
- Eye protection
- Hearing protection
- Respiratory protection
- Gloves
- Boots
- Coveralls
- Turnout coat and pants
- Specialty equipment
- Reflective clothing

Mental and Emotional Health

Many factors play a role in mental and emotional health. An important factor is to be aware of "warning signs" that could indicate a potential problem (e.g., signs of substance misuse and health disorders caused by **anxiety** and **stress**). Also key to maintaining good emotional health is realizing the value of having personal time; being connected with family, peers, and the community; and accepting the personal differences that make individuals unique.

SUBSTANCE MISUSE AND ABUSE CONTROL

Health care workers, emergency responders, and public service personnel are not immune to stressors that can lead to substance misuse and abuse. Studies have found that 8% to 12% of physicians were estimated to develop a substance use problem;[11] 32% of nurses reported some substance abuse;[12] and about 30% of firefighters and law enforcement officers reported problematic alcohol use.[13]

The misuse and abuse of drugs and other substances may lead to chemical dependency (**addiction**) (Box 2-12). Such dependency may have a wide range of effects on physical and mental health, including damage to vital organs, cancer, increased risk for injuries, and mental impairment (see Chapter 34). Warning signs of addiction and addictive behavior include the following:

BOX 2-12 Common Drugs and Substances That Are Misused or Abused

- Alcohol
- Central nervous system stimulants (e.g., cocaine and amphetamines)
- Cigarettes and other tobacco products
- Hallucinogens
- Inhalants
- Marijuana
- Narcotics and related drugs
- Sedative-hypnotics
- Tranquilizers
- Nonprescription substances
- Sedatives
- Appetite suppressants
- Laxatives
- Cough and cold preparations
- Nasal sprays
- Analgesics

- Using a substance to relieve tension
- Using an increasing amount of the substance
- Lying about using the substance
- Experiencing guilt about using the substance
- Avoiding discussion about using the substance
- Experiencing interference with daily activities as a result of substance abuse

CRITICAL THINKING
Do you know anyone with these behaviors?

Methods used to manage substance abuse depend on the type of substance being misused. Substance misuse or abuse control may call for professional counseling. Physician-controlled drug therapy and support programs also may be necessary.

SMOKING CESSATION

Cigarette smoking is a major health hazard. Smoking is responsible for more than 438,000 deaths each year in the United States.[14] The health ramifications of cigarette smoking are numerous, including an increased risk of the following:

- Coronary heart disease
- Myocardial infarction
- Chronic obstructive pulmonary disease
- Sudden death
- Dying from a variety of diseases
- Miscarriage, premature birth, and birth defects

Smokers often name many reasons for continuing to smoke. These reasons may include peer pressure, relief of stress, weight control, and others. Regardless, most persons continue to smoke because of the addictive nature of nicotine. Nicotine is the stimulant in tobacco, but there are other harmful chemicals. These chemicals include hydrocarbons (tar) and carbon monoxide. Exposure to these chemicals is considered a health hazard for nonsmokers also. Nonsmokers have an increased risk of developing smoking-related illnesses through "passive smoking," or second- and third-hand smoke.

Many resources and smoking cessation programs are available to those who want to quit smoking. Support groups and quit-smoking campaigns are sponsored by the American Heart Association, the American Cancer Society, the American Red Cross, government health agencies, and local health care organizations. Other methods one may use alone or with these programs include the use of prescription and nonprescription drugs. Some examples include Chantix, Wellbutrin, dermal patches, and nicotine chewing gum. These products decrease the physical effects of smoking cessation. In a sense, they help to wean the smoker off nicotine (Box 2-13).

ANXIETY AND STRESS

Anxiety can be defined as the worry or dread about future uncertainties. *Stress* can result from the interaction of events that cause anxiety and the coping abilities of the person. Stress can be positive (described later in this chapter). However, stress usually is thought of as having a negative effect (e.g., fear, depression, and guilt). Recognizing and coping with anxiety and stress is important for a lasting career in the EMS profession. Signs that you may need stress management assistance include[15]:

BOX 2-13 Body Changes When You Stop Smoking

Within 20 Minutes of Your Last Cigarette
Pulse and blood pressure drop to normal.
Body temperature of hands and feet increases to normal.

Within 8 Hours of Your Last Cigarette
Carbon monoxide level in blood drops to normal.
Oxygen level in blood increases to normal.

Within 24 Hours of Your Last Cigarette
Chance of heart attack decreases.

Within 48 Hours of Your Last Cigarette
Nerve endings begin to regenerate.
Ability to smell and taste is enhanced.

Within 72 Hours of Your Last Cigarette
Bronchial tubes relax, making breathing easier.
Lung capacity increases.

Within 2 Weeks to 3 Months After Your Last Cigarette
Circulation improves.
Walking becomes easier.
Lung function increases up to 30%.

Within 1 to 9 Months After Your Last Cigarette
Coughing, sinus congestion, fatigue, and shortness of breath decrease.
Cilia regrow in lungs, increasing the ability to handle mucus, clean the lungs, and reduce infection.

Within 5 Years of Your Last Cigarette
Lung cancer death rate for the average smoker (one pack per day) decreases.

Within 10 Years of Your Last Cigarette
Lung cancer death rate drops to 12 deaths per 100,000—almost the rate of nonsmokers.
Precancerous cells are replaced.
Risk for other cancers—such as those of the mouth, larynx, esophagus, bladder, kidney, and pancreas—decreases (20 chemicals in tobacco smoke cause cancer).
When smokers quit, the health improves over time.
See www.cancer.org/docroot/SPC_1 when smokers_quit.asp.

- Disorientation or confusion and difficulty communicating thoughts
- Difficulty remembering instructions
- Difficulty maintaining balance
- Becoming easily frustrated and being uncharacteristically argumentative
- Inability to engage in problem solving and difficulty making decisions
- Unnecessary risk taking
- Tremors/headaches/nausea
- Tunnel vision/muffled hearing
- Colds or flulike symptoms
- Limited attention span and difficulty concentrating
- Loss of objectivity
- Inability to relax when off duty
- Refusal to follow orders or to leave the scene
- Increased use of drugs/alcohol
- Unusual clumsiness

PERSONAL TIME FOR MEDITATION AND CONTEMPLATION

Setting aside some personal time can boost mental and perhaps even physical health. This time can be spent meditating or contemplating. *Meditation* is a form of relaxation. To meditate, a person limits his or her awareness to a repeated or constant focus. The person may focus on something that holds some attraction (e.g., controlled breathing, a pleasant site, a fragrance, or a mantra). This quiet time provides an uninterrupted period for thoughtful introspection *(contemplation)* of important things in a person's life. Most who practice meditation do so once or twice a day for 10 to 20 minutes.

NOTE
Spirituality is a unique quality of human existence. Spirituality should not be overlooked as a means for some to achieve mental and physical well-being.

DIVERSITY AND FREEDOM FROM PREJUDICE

The concept of **diversity** encompasses acceptance and respect of other people. It means understanding that each person is unique and recognizing our individual differences. These differences can be along the dimensions of race, ethnicity, gender, sexual orientation, socioeconomic status, age, physical abilities, religious beliefs, political beliefs, or other ideologies (Figure 2-4).

Accepting differences in people provides an opportunity to learn about others and to see variations in people in a positive light. Acceptance also affirms the value of these differences. It allows paramedics to see life from another viewpoint. Being able to work with others in a diverse workplace is also essential. Following are some general guidelines:

1. Maintain a personal attitude about others that "includes" rather than "excludes."

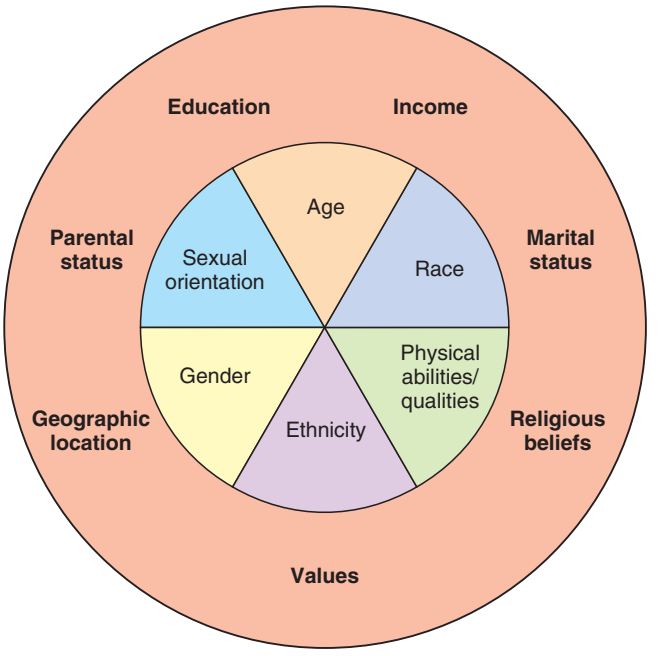

FIGURE 2-4 Dimensions of diversity.

2. Treat everyone with respect, including patients, your co-workers, those to whom you report, and those who report to you.
3. Do not assume that everyone shares your beliefs.
4. Examine your assumptions about people who are different than you.
5. Learn to listen carefully and observe those around you to be more aware of their needs, boundaries, and differences.

NOTE
The four major ethnic minority groups in the United States are Hispanic/Latinos (Mexican-American, Puerto Rican, Cuban, Central and South American), Asians (Chinese, Korean, Japanese), Southwest Asians (Vietnamese, Laotians, Cambodians), and African Americans. Providing health care to patients of some cultures may call for special communication skills. Provision of care also may require some further education to understand the customs and beliefs of that culture (see Chapter 17).

STRESS

As previously stated, stress can be positive and negative. The responses to stress may be physical, emotional, or both. "Good" stress (**eustress**) is a positive response to stimuli. Eustress is considered protective. "Bad" stress (**distress**) is a negative response to environmental stimuli. Distress is the source of anxiety and stress-related disorders.

Phases of the Stress Response

Hans Selye was an Austrian-born professor at the University of Montreal. He coined the term *stress* in its medical

usage in 1950. The three stages of the stress response he found are the alarm reaction, resistance, and exhaustion (Figure 2-5).[16] Selye called these phases the *general adaption syndrome*. He gave them this name to describe the attempt of body and mind to deal with stressful events.

ALARM REACTION

The human body can prepare itself quickly to do battle or run from danger. This "fight-or-flight" reaction occurs when a situation threatens one's safety or comfort. This reaction is considered positive (eustress) in that it prepares individuals to be alert and to defend themselves. At first, the response of the body to stress is unaffected by the type of situation. The body reacts equally to events that are pleasant or unpleasant, dangerous or exciting, happy or sad. The purpose of the response is to achieve top physical preparedness rapidly to cope with the event. Examples would be having an argument with a co-worker, performing an unfamiliar patient care procedure, and taking part in the delivery of a healthy infant.

The alarm reaction is triggered by the **autonomic nervous system** (see Chapter 10). This reaction is coordinated by the hypothalamus. The hypothalamus triggers the pituitary gland to release adrenocorticotropic hormone into the bloodstream. This stress hormone stimulates the production of glucose. The hormone also increases the concentration of nutrients in the blood that provide energy. These nutrients are needed for the response to stress. Adrenocorticotropic hormone also activates the adrenal glands for an intense sympathetic discharge of **adrenaline** and noradrenaline. These hormones cause the heart rate to increase, the blood pressure to rise, and the pupils of the eyes to dilate, which improves vision. Together these hormones relax the bronchial tree for deeper breathing, increase blood sugar (glucose) for total energy, slow the digestive process, and shift blood supply to accommodate the clotting mechanism in case the body is wounded. After these physiological events, the body is ready for an emergency (fight or flight). The body can perform feats of strength and endurance far beyond its normal capacity. The alarm reaction takes only seconds. The reaction occurs to some extent at the first exposure of the body to a stressor. When the body realizes that an event is not dangerous or does not require the alarm reaction, the response stops. The individual begins to adapt to the situation. Then bodily functions return to normal.

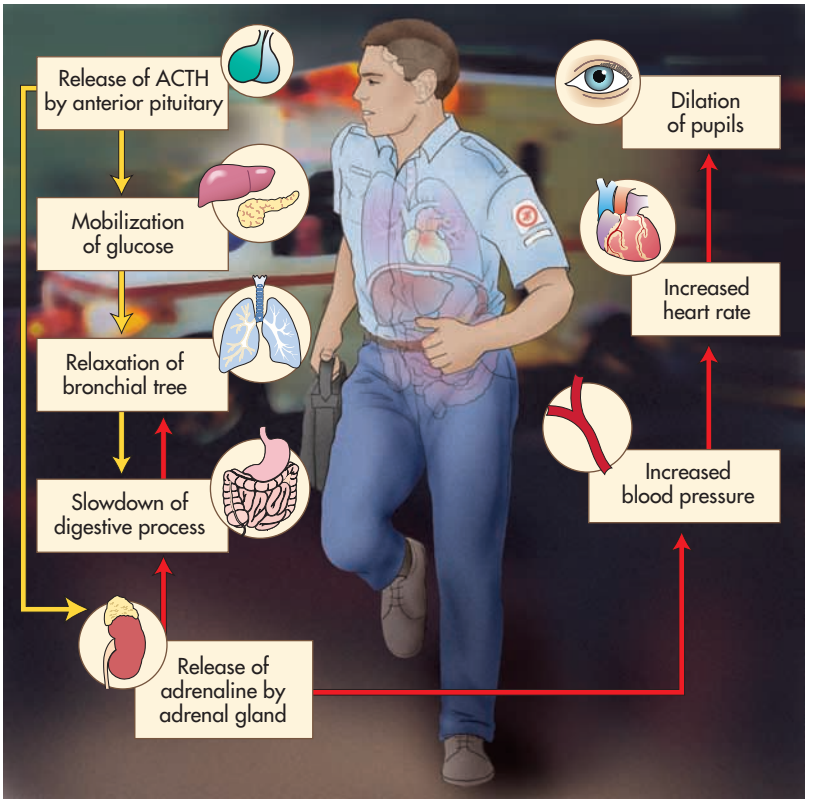

FIGURE 2-5 Physiological response to stress. During the alarm reaction, the release of adrenocorticotropic hormone (*yellow*) results in a sympathetic discharge of adrenaline (*red*). These stress hormones stimulate glucose production and cause the heart rate to increase, the blood pressure to rise, and the pupils to dilate. The bronchial tree relaxes for deep breathing, the digestive process slows, and the blood supply shifts to accommodate clotting mechanisms in case the body is wounded.

RESISTANCE

The stress response raises the level of resistance to the agent that provoked it and others like it. That is, if a particular stress persists long enough, a person's reactions change. For example, a paramedic becomes accustomed to responding to emergency scenes in an ambulance using audible and visual warning devices. Thus the alarm reaction that once occurred is no longer elicited. Therefore reactions to stressors may change over time.

EXHAUSTION

As stress continues, coping mechanisms weaken. Then resistance fails. For example, paramedics may appear to be unaffected by the stress of life-threatening emergencies. However, all of their adaptive resources have been used to reach this stage of resistance. When any reservoir of adaptive resources no longer exists, resistance to other types of stress tends to decline as well. At that point, the body may become at risk for physical and psychological illness. Rest and recovery usually are needed before a person is ready for another emergency.

Factors That Trigger the Stress Response

Each person has unique means to deal with stressful situations. Individual reactions to stress are customized based on previous exposure to a specific type of stress, perception of the stressful event, and personal coping skills. Many factors can trigger the stress response. Examples include the following:

- Loss of something that is of value
- Injury or threat of injury
- Poor health or nutrition
- Frustration
- Ineffective coping skills

PHYSIOLOGICAL AND PSYCHOLOGICAL EFFECTS OF STRESS

Anxiety is a common symptom of stress. Feeling anxious in certain situations or unusual circumstances is normal and healthy. This response provides a warning system that protects persons from being overwhelmed by a sudden stimulation. Anxiety also prepares persons for action in critical situations. This adaptive response to stress prepares the paramedic to make quick, correct decisions regarding the emergency. Anxiety also allows the paramedic to perform at maximal efficiency.

Sometimes stress is not reduced by a solution to the conflict or emergency. This may lead to an ongoing state of vigilance and alertness beyond the initial event. The paramedic then may begin to feel chronic anxiety. This kind of anxiety fails to stimulate effective coping. In addition, a person may respond to conflict or stress by anxious behavior alone. Anxiety interferes with thought processes and with relationships and work performance. A person may develop problems concentrating, lose the ability to trust others, or become isolated or withdrawn.

Individuals who are exposed to stressful situations often or who are unable to cope with stressful events may experience a chronic state of anxiety. This state may lead to physical, emotional, cognitive, and behavioral effects (Box 2-14). Some warning signs may call for immediate evaluation and medical care. These signs include chest pain and difficulty breathing. Others call for less immediate action. The presence of one or more warning signs is an indicator of distress. However, the absence of warning signs does not preclude the chance of a stress reaction.

CAUSES OF STRESS IN EMERGENCY MEDICAL SERVICES

A variety of sources can produce stress in EMS work. Environmental stress includes noise, bad weather, confined spaces, poor lighting, spectators, rapid response to the

BOX 2-14 Warning Signs and Symptoms of Stress

Physical

- Cardiac rhythm disturbances
- Chest pain
- Difficulty breathing
- Nausea
- Profuse sweating
- Sleep disturbances
- Vomiting

Emotional

- Anger
- Denial
- Fear
- Feeling of being overwhelmed
- Inappropriate emotions
- Panic reactions

Cognitive

- Confusion
- Decreased level of awareness
- Difficulty making decisions
- Disorientation
- Distressing dreams
- Memory problems
- Poor concentration

Behavioral

- Changes in eating habits
- Crying spells
- Excessive silence
- Hyperactivity
- Increased alcohol consumption
- Increased smoking
- Withdrawal

scene, and life-and-death decision making. Psychosocial stress may arise from family relationships and can come from conflicts with co-workers, abusive patients, and similar sources. Personality stress relates to the way a person thinks and feels. For example, this kind of stress can include the need to be liked. Personality stress can include one's expectations and feelings of guilt and anxiety as well. Choosing a career in EMS requires developing an understanding of job-related stress and effective stress management.

REACTIONS TO STRESS

Certain types of persons may be attracted to certain types of careers. For example, some believe that EMS personnel, firefighters, police officers, and others in public safety are predisposed to stressful and demanding jobs.[17] However, no person is immune from potential conflicts in managing stress.

ADAPTATION

Adaptation is a process that involves learning successful ways to deal with stressful situations. This process usually begins with using defense mechanisms. Next, adaptation focuses on developing coping skills, followed by problem solving. Finally, adaptation concludes with mastery.

Defense mechanisms are adaptive functions of the personality (Box 2-15). They assist a person in adjusting to stressful situations and help a person to avoid dealing with problems. *Denial*, for example, is a defense mechanism. Denial might be used to separate a person from the event long enough to deal with a problem that normally would be overwhelming.

Coping is an active confronting process. Coping involves gathering information and using the information to change or adjust to a new situation. Some beneficial ways to cope include taking part in regular physical exercise and being involved in activities at work that result in financial rewards and increased productivity. Other positive ways to cope include finding humor in personal crises, and "talking through" stressful events with family, friends, and co-workers.

Persons also may use harmful or negative coping mechanisms. An individual may become withdrawn or use alcohol or other drugs. Some may have angry outbursts toward family members and co-workers. Others may become silent. These negative coping mechanisms threaten interpersonal relationships with co-workers and loved ones. They should be seen as signs that an individual is having trouble dealing with stress.

NOTE

Burnout can be the result of cumulative stress. The condition is defined by physical and emotional exhaustion and negative attitudes. Burnout can develop when one is exposed to chronic stress that cannot be managed with usual coping mechanisms.

Problem solving involves analyzing a problem and finding options to deal with the issue now and in the future. Problem solving allows a person to clearly identify the problem and determine a course of action. This is a healthy approach to everyday concerns.

Mastery refers to the ability to see multiple options and solutions for challenging situations. Mastery results from extensive experience and the use of effective coping mechanisms with situations that are very similar. Mastery may be difficult to achieve.

STRESS MANAGEMENT TECHNIQUES

To manage stress well, a person must recognize the early warning signs of anxiety. Some of the physical effects of anxiety an individual may notice include the following:

- Heart palpitations
- Difficult or rapid breathing
- Dry mouth
- Chest tightness or pain
- Anorexia (lack of appetite), nausea, vomiting, diarrhea, abdominal cramps, flatulence, "butterflies"
- Flushing, diaphoresis (profuse sweating), body temperature fluctuation
- Urgency and frequency in urination
- Dysmenorrhea (painful menstruation), decreased sexual drive or performance
- Aching muscles, joints

Physical effects that may not be as noticeable include the following:

- Increased blood pressure and heart rate
- Increased blood glucose levels
- Increased adrenaline production by adrenal glands
- Reduced gastrointestinal peristalsis
- Pupillary dilation

CRITICAL THINKING

Compare your reactions while on a highly stressful call in the field to those you experience when stressed about school. How are those feelings similar or different from each other?

Many warning signs appear during the emergency response or within 24 hours after the event. Some responses, however, may be delayed for some time and may not appear for months or years after the event. If signs and symptoms of stress-related illness appear, the person should seek appropriate medical or psychological help.

Intervening to relieve stress is as important as recognizing the warning signals. Methods one may use initially to manage stress include reframing, controlled breathing, progressive relaxation, and guided imagery. All of these methods require practice to perform them properly. *Reframing* involves first looking at the situation from a different emotional viewpoint and then placing it in a different "frame" that fits the facts of another situation equally well. This acts to change the meaning of the situation. *Controlled*

BOX 2-15 Common Defense Mechanisms

Repression
Repression is thought to be the mechanism underlying all other defense mechanisms. Repression is the involuntary attempt to keep certain feelings or memories from reaching conscious awareness. Traumatic events, intolerable and dangerous impulses, and other unacceptable ideas are forced out of consciousness. This defense mechanism may be seen as a result of an approach-avoidance conflict. This is a conflict between trying to recall or think about something and trying to avoid the topic because it creates fear. Once repressions form, they usually are difficult to abolish. The individual must be reassured that no danger exists in recalling the event. For example, an emergency medical services (EMS) co-worker is killed while on duty. The partner has no recall of the event from the time they arrived at the scene until after the event.

Regression
Regression is a return to earlier levels of emotional adjustment. Of all the reactions to anxiety and danger, regression may be the most dramatic and debilitating. A person returns to an earlier developmental phase of life. This phase may have been a time when tension and conflict could be avoided. For example, an EMS worker throws a temper tantrum because he was assigned driver status on a work shift when he thought he would have direct patient care duties.

Projection
Projection involves attributing one's own undesirable qualities, feelings, motives, or desires to someone else. Projection may appear as aggression toward others. However, the problem is actually self-anger. Often individuals are wrong in labeling their own motives and the motives of others. For example, a paramedic crashes an emergency vehicle en route to a call. Because of guilt, she feels that others blame her for the crash. In fact, she is blaming herself.

Rationalization
Rationalizations occur when persons feel the need to explain their behavior. This need may be a result of social training. They feel the need to explain because the true explanation would cause anxiety or guilt. A person is trying to prove that the behavior is "rational" and therefore worthy of the approval of self and others. Rationalization is a commonly used defense mechanism. For example, a paramedic performs a poor physical examination on a trauma patient. She fails to discover a femur fracture. When questioned by medical direction, she justifies her actions by saying that the police were hurrying her to clear the scene.

Compensation
Compensation is trying to cover up for a real or imagined weakness. One compensates by stressing a more positive trait or skill. This conceals frustration and anxiety by focusing attention on other behavior. For example, an EMS crew member has weak clinical skills and feels inadequate at emergency scenes. He compensates by becoming an instructor in water rescue.

Reaction Formation
Reaction formation is a defensive behavior that prevents unwanted desires from being expressed. The person exaggerates opposing attitudes and behavior, thereby expressing the opposite of the true motive. The original impulse is still present. However, the impulse is masked by actions or attitudes that do not cause anxiety or stress. For example, a paramedic is outwardly friendly to a co-worker whom she dislikes.

Sublimation
Sublimation is a form of substitution. Sublimation entails changing undesirable urges so that they are socially acceptable. Sublimation is a defense mechanism. However, the functions of sublimation are thought to extend beyond that of protection. Sublimation requires changing one's focus or energy. In this change, instinctual drives are substituted for ones that may result in a higher cultural achievement. For example, a paramedic may become angry from seeing people die in drunk-driving crashes. Thus he starts a public awareness program on the hazards of drinking and driving.

Denial
Denial is another defense mechanism. In denial the person rejects elements of reality that knowingly would be intolerable. The person gains protection from unpleasant reality by refusing to see it. The person may deny the event itself or the memory of it. For example, a person who has just lost a loved one may be unable to accept the reality of death. (Denial differs from repression. Persons who use repression as a defense mechanism seem deliberately to keep their feelings or memories at a distance from the conscious mind.)

Substitution
Substitution is a defense mechanism that switches another activity or goal for one that is desired but unreachable. Substitution may involve the redirection of an emotion from the first object to a more acceptable one. Substitution often results from frustration. For example, a co-worker is having marital problems. He feels that it is unacceptable to argue with his spouse. He substitutes and displaces his anger at work by being irritable, grouchy, and hostile toward other crew members.

Isolation
Isolation involves the separation of unacceptable impulses, acts, or ideas from their origin in memory. This defense mechanism removes the emotional charge from the event. Isolation prevents feelings from being linked to the memory. Isolation may be helpful to the paramedic who must turn off feelings until after a call. For example, a paramedic may also be a parent and may have to give care to a dying child without being overcome by emotions.

breathing is a natural stress control technique. A person concentrates on depth and rate of breathing to achieve a calming effect. Controlled breathing may begin with deep breathing, followed by less deep breathing, and finally normal breathing. *Progressive relaxation* is a stress reduction strategy in which the person systematically tightens and relaxes particular muscle groups (from head to toe or from toe to head). This "fools" the brain into initiating muscle relaxation throughout the body. *Guided imagery* is used with meditation. Another person familiar with the technique acts as a guide during a stress response. The person experiencing stress then can focus on an image that helps relieve stress. (Once guided imagery is learned, a person can use the technique without prompting.)

Other ways to fight stress include being aware of personal limitations, taking part in peer counseling, and participating in group discussions. Proper diet, exercise, sleep, and rest also help to relieve stress. In addition, pursuing positive activities outside of EMS can balance work and recreation. The responsibility for personal health and well-being belongs to the individual. However, intervention programs may be available through EMS agencies, hospitals, and other groups.

CRITICAL INCIDENT STRESS MANAGEMENT

Critical incident stress management (CISM) evolved from the early 1970s concept of critical incident stress debriefing. This program was developed to help emergency workers exposed to a major incident. CISM is based on a partnership between mental health professionals and peer group support. Although the benefits of CISM as a form of psychological first aid are debated,[18] CISM is designed to give emergency workers a chance to vent their feelings about a call or event that had a major impact (Box 2-16).

Critical incident stress management aims to help emergency workers understand their reactions. It reassures them that what they are experiencing is normal. It also reassures them that what they are feeling may be common to others involved in the incident. The process may be for one person or may include various members of the emergency team (e.g., police, EMS crew members, firefighters, and emergency department staff).

BOX 2-16 Potential Situations for Critical Incident Stress Management

- Line-of-duty injury or death
- Disaster
- Emergency worker suicide
- Infant/child death
- Extreme threat to emergency worker
- Prolonged incident that ends in loss or success
- Victims known to operations' personnel
- Death/injury of civilian caused by operations
- Other significant event

NOTE

There are many programs available to EMS personnel and their families that can help manage stress. These include employee assistance programs, counseling, spouse support programs, family life programs, pastoral services, and periodic stress evaluations. These efforts and others can be good resources to the paramedic in dealing with stress on the job (see Box 2-16).

POSTTRAUMATIC STRESS DISORDER (PTSD)

Posttraumatic stress disorder is an anxiety disorder that can occur following a traumatic event. These events can include:

- Combat or military exposure
- Child sexual or physical abuse
- Terrorist attacks
- Sexual or physical assault
- Serious incidents, such as a car crash
- Natural disasters, such as a fire, tornado, hurricane, flood, or earthquake

Recent studies have indicated that EMS personnel are more likely than the general public to suffer from PTSD.[19] The emotional difficulties that can result from dealing regularly with traumatic calls can lead to increased absenteeism from work, a troubled family life, and increased alcohol or other drug use. PTSD may also increase the risk of suicide.

There are four types of symptoms associated with PTSD. They include reexperiencing, numbing, avoidance, and arousal.[20]

1. Reexperiencing is a mental "replay" of the event. It is often accompanied by strong, emotional reactions. This can occur during waking hours or during sleep (nightmares).
2. Avoidance refers to efforts to evade activities, places, or people that remind those with the disorder of the traumatic event.
3. Numbing is typically experienced as a loss of emotion, particularly positive feelings.
4. Arousal reflects excessive psychological activation. Examples include a heightened sense of being "on guard" as well as difficulty with sleep and concentration.

The symptoms of PTSD are often managed with counseling, behavior therapy, and sometimes medication. Brief "time-out" periods from work (1 to 8 weeks) and support from co-workers and supervisors may also aid EMS personnel in their recovery (Box 2-17).[21]

BOX 2-17 Techniques for Reducing Crisis-Induced Stress

- Allow adequate rest for emergency workers.
- Provide food and fluid replacement.
- Limit exposure to the incident.
- Change assignments.
- Provide postevent defusing/debriefing.

CRITICAL THINKING
Imagine which type of call would be a critical incident for you personally.

DEALING WITH DEATH, DYING, GRIEF, AND LOSS

Death and dying always will be part of health care delivery. Medical science has given society the ability to postpone death in some instances and perhaps lessen its physical pain. However, the fight for self-preservation is still inevitably lost.

Patient and Family Needs

In the delivery of EMS, paramedics at times will give care to a dying person surrounded by loved ones. In such cases, the emotional needs of the dying patient, family, and loved ones should be of utmost importance. The patient and significant others will need to be comforted, given privacy, and treated with respect and dignity. Loved ones may need to express feelings of rage, anger, despair, and guilt. They may need the paramedic to provide control and direction for this solemn event. The paramedic's role in these cases is important and may be a determining factor in the way survivors adjust to their loss (Box 2-18).

Stages of the Grieving Process

In 1968 Elisabeth Kübler-Ross began her work on the psychological aspects of death and dying. Her studies identified five predictable stages of dying: denial, anger, bargaining, depression, and acceptance. Kübler-Ross found that patients and loved ones dealing with the death process generally experience the following five stages:[22]

1. *Denial* is characterized by the feeling "No, not me." Denial is an expected response to news of a life-threatening illness or situation. The news is so overwhelming that it must be absorbed slowly. The patient seeks other opinions, verifies the accuracy of medical reports, or simply seems to ignore what he or she has been told. Denial is a valuable defense mechanism. Denial is troubling only when no indication exists that the patient understands the seriousness of the situation. Most patients, families, and friends deny death to some degree to continue with the daily business of living.
2. *Anger* can be viewed as the "Why me?" phase. Anger is probably the most difficult for persons who care about or are trying to help the dying person. In this phase, the person rejects all efforts to help or console. This anger is really the anger of the dying person toward all the persons who continue to live. More accurately, anger may be anger directed toward God because He does not appear to have acted fairly or justly with the dying person.
3. *Bargaining* is reflected in a "Yes, me, but ..." frame of mind. The person admits the reality of being sick and of probably dying, but the person tries to bargain for extension or quality of life. These bargains usually are secret, frequently are made with God, and rarely are kept. For example, a father promises to be a "perfect patient" if only he can live to see his son's wedding.
4. *Depression* is the "Yes, me" reaction to anticipated death. Depression involves preparing to say and saying goodbye to everything and everyone a person has known and loved. The inherent sadness of this phase is appropriate and should be respected.
5. *Acceptance,* the simple and quiet "Yes," grows out of individuals' convictions that they have done what they could to be ready to die. Personal energy and interpersonal interests decrease significantly. During this phase, relatives and friends usually need more help than the dying person. The dying person's most important wish at this point is not to die alone.

NOTE
Dying patients and their loved ones may fluctuate between these stages and may or may not experience all five stages.

SHOW ME THE EVIDENCE
Researchers surveyed families of patients in whom they terminated resuscitation of asystolic cardiac arrest in the field. They found that field resuscitation termination was accepted by the patients' families. The system had predefined termination criteria and a preplan that included a mechanism for family support (other than the EMS crew). Follow-up of these nontransported families in 3 to 6 months indicated that their grief adjustment trended more positively than that observed in families whose deceased family member was transported.

From Edwardsen EA, Chiumento S, Davis E: Family perspective of medical care and grief support after field termination by emergency medical services personnel, *Prehosp Emerg Care* 6(4):440-444, 2002.

Paramedics rarely are involved in a patient's process of coming to terms with death. However, they often see the reactions of patients and families going through the death process. For example, denial may be obvious in some family members. These people may not appear to see or

BOX 2-18 Hospice Programs

Hospice programs began in England in 1967. They since have become a standard service of many health care institutions in the United States. Their goal is to help the terminally ill patient, family, and loved ones cope when death is expected. The hospice philosophy supports home care for the patient. Home care provides for a more natural environment. In addition, volunteers and health care professionals provide counseling and other psychological support to the patient and family during the death process. Hospice programs are well respected in the medical community. The programs play an important role in helping patients and their families accept death as a natural event in life.

acknowledge the seriousness of a situation in which decisions about resuscitation must be made. Anger may be directed at the paramedic crew or other health care workers. Bargaining may occur in the form of a mother who says, "Please save my child, and I promise that I'll always make her wear her seat belt!" The paramedic must realize the psychological aspects of the stages of grief.

When it is necessary to give news of a sudden death to a family, the paramedic's initial contact can influence the grief response greatly. The paramedic should gather the family in a private area and advise them of the patient's death, with a brief account of the situation causing the death. The paramedic should use the words *death* or *dead* and should avoid euphemisms such as "he's passed on" or "she's no longer with us." The paramedic should be compassionate and allow time for the news to be absorbed and for questions to be asked. The family members should be allowed to see the relative if they choose. They should be told in advance if resuscitation equipment is still connected to the patient. These efforts, along with empathic interaction with the family, help relatives deal with the loss of a loved one (Box 2-19).

Common Needs of the Paramedic When Dealing With Death and Dying

Dealing with death is difficult for everyone. Thus the paramedic's feelings and emotions also must be considered. The paramedic may experience some of the same stages of grief described earlier. These reactions are normal and a great deal of effort to disguise or suppress these emotions may be required at the scene or while rendering care. However, the paramedic should discuss these feelings as soon as possible with friends, co-workers, and family in a constructive way that will lessen the emotional burden. Like others, the paramedic will need a chance to process the incident and obtain closure. Available resources, such as employee assistance programs and counseling and pastoral services, help avoid the effects of cumulative stress.

BOX 2-19 Recommended Communication Strategies

A situation involving death and dying is uncomfortable. Communication with the patient and loved ones may be difficult. The following recommendations for communications and activities may help a paramedic deal with dying patients and their families:

- Answer questions honestly for the patient and family and explain all activities.
- Do not initiate the subject of dying; let it come from the patient or family.
- If the patient or family asks you whether the patient is going to die, advise that you are doing everything you possibly can but that the situation is critical. This allows a brief time for the patient and family to prepare themselves.
- Do not falsely reassure the patient or family (e.g., "everything's going to be okay").
- Use compassionate, nonverbal communication (facial expression, touching).
- Offer to contact someone if the patient is alone.
- If family is not present, assure the patient that emergency department personnel will notify them. If they are nearby, encourage the family to come to the patient immediately or to meet the patient at the emergency department.
- Allow the family to stay with the patient when appropriate.

CRITICAL THINKING

What personal experiences have you had with death? How did you or others who were close to the deceased react to the initial news of the death?

Developmental Considerations When Dealing With Death and Dying

The way persons cope with their own death or the death of a loved one depends on their age, maturity, and understanding of death. The paramedic should be sensitive to the emotional needs of all age groups during this crisis. The following guidelines may be helpful when offering advice to family members who will be helping the young or elderly cope with the death of a loved one.[23]

Children up to age 3 probably will sense that something has happened in the family. They will realize that others are sad and crying. They also may be aware of increased activity in the household. The family should be urged to watch for changes in eating or sleeping patterns and for an increase in irritability. In addition, the family should be sensitive to the child's needs and try to maintain consistency in the child's routines and with significant persons in the child's life.

Children 3 to 6 years of age do not have a concept of the finality of death. They may believe that the person will return and may ask "when" continually. This age group believes in magical thinking and may feel that they are responsible for the death. They also may believe that everyone else they love will die too. The family should watch for changes in the child's behavior patterns with friends and at school, for difficulty sleeping, and for changes in eating habits. The family should emphasize that the child is not responsible for the death. The family should reinforce the fact that crying is normal when persons are sad and should encourage children to talk about their feelings.

Children 6 to 9 years of age are beginning to understand the finality of death. They want detailed explanations for the death and can differentiate fatal illness from just "being sick." Like the 3- to 6-year-olds, these children may be afraid that other loved ones will die too. This age group may be uncomfortable with expressing their feelings and may act silly or embarrassed when talking about death. The paramedic should suggest to the family that they talk about the

normal feelings of anger, sadness, and guilt and that they share their own feelings about death with the child. The family members should not hesitate to cry because crying will let the child know that expression of feelings is acceptable.

Children 9 to 12 years of age are aware of the finality of death. They may want to know the details surrounding the event. They will be concerned with practical matters involving their lifestyle and may try to "act like an adult." (Most of these children, however, will show regression to an earlier stage of emotional response.) The paramedic should suggest to the family that they set aside time to talk to the child about feelings and encourage the sharing of memories to aid in the grief response.

Older adults usually show concern for other family members. In addition, they may be worried about their further loss of independence and about financial matters at hand. Family members should be sensitive and understanding about these issues because they are real for this age group.

PREVENTION OF DISEASE TRANSMISSION

Emergency workers often manage ill and injured patients. Thus prevention of disease transmission must be a priority in daily practice. Specific concerns arise for personal health and safety. One concern includes being aware of common sources of exposure. Another includes using personal protection. Finally, one must know what to do if an exposure has occurred (Box 2-20).

Common Sources of Exposure

Common sources of exposure to infectious agents in the prehospital setting include needlesticks and broken or scraped skin. Mucous membranes such as those that line the eyes, nose, and mouth also are a source for entry of infectious agents or microorganisms. As a result, the paramedic must practice universal precautions during all patient care encounters (see Chapter 14).

Paramedic Protection From Airborne and Blood-Borne Pathogens

The following list contains some general guidelines to help prevent exposure to infectious diseases (a more complete discussion of infectious disease is presented in Chapter 28).

1. Follow engineering and work practices. Maintain good personal health and hygiene habits. (Wash hands frequently and pay attention to general cleanliness.)
2. Maintain immunizations for tetanus, diphtheria, pertussis, polio, hepatitis B, MMR (measles, mumps, and rubella), and influenza.
3. Conduct a periodic screening for tuberculosis.
4. Practice universal precautions in all encounters with patients.
5. Properly clean, disinfect, and dispose of used materials and equipment immediately.
6. Use puncture-resistant containers to dispose of needles and other sharp objects.
7. Separate and label all soiled laundry (clothes, bed linens). Also separate and label all equipment. Do this until the items can be cleaned and disinfected properly.
8. Conduct a periodic risk assessment of health.

BOX 2-20 Disease Transmission Terminology

Airborne and blood-borne pathogens are organisms respectively carried through air and blood (and other body fluids). These organisms create disease in the human body or host. Some pathogens (e.g., certain bacteria) can survive outside a host. Others (such as viruses) can survive only in the human cell (see Chapter 28). Exposure occurs in cases of contact with a likely infectious body fluid or other infectious agent. Certain steps are used to destroy infectious organisms that may have come in contact with equipment and instruments. These steps include cleaning, disinfection, and sterilization. Universal precautions are practices to prevent or reduce contact with body substances and other infectious agents.

Documentation and Management of an Exposure

The paramedic must be familiar with laws, regulations, and national standards that address issues of infectious disease and take personal protective measures against exposure. In the event of a potential exposure to an infectious disease or a significant exposure to a patient's blood or body fluids, the paramedic should do the following:

1. Wash the area of contact with soap and water thoroughly and immediately.
2. Immediately document the situation in which the exposure occurred.
3. Describe actions taken to reduce chances of infection.
4. Comply with all required reporting responsibilities and time frames.
5. Cooperate with incident investigation.
6. Be screened for antibody titers and potential infectious diseases.
7. Obtain proper immunization boosters.
8. Obtain a full medical follow-up.

SUMMARY

- Wellness has two main aspects: physical well-being and mental and emotional health.
- As health care professionals, paramedics have a responsibility to serve as role models in disease prevention.
- Persons who are overweight tend to be at risk for developing certain illnesses. A healthful diet includes a variety of foods that are low in fat, saturated fat, and cholesterol. The calories in the diet should be regulated to prevent unwanted weight gain.
- Physical fitness can be described as a condition that helps individuals look, feel, and do their best.
- Sleep helps to rejuvenate a tired body.
- Steps to reduce cardiovascular disease include the following: improving cardiovascular endurance, eliminating cigarette smoking, controlling high blood pressure, maintaining a normal body fat composition, maintaining good total cholesterol/high-density lipoprotein ratio, monitoring triglyceride levels, controlling diabetes, avoiding excessive alcohol, eating healthy foods, reducing stress, and making a periodic risk assessment.
- Most common cancers are linked to one of three environmental risk factors: smoking, sunlight, and diet.
- The paramedic's duty is to be familiar with laws, regulations, and national standards that address issues of infectious disease. The paramedic also must take personal protective measures to guard against exposure.
- Actions to take after significant exposure include disinfection, documentation, incident investigation, screening, immunization, and medical follow-up.
- Injuries on the job can be minimized. Knowledge of body mechanics during lifting and moving is helpful. Also, being alert for hostile settings is key. Prioritization of personal safety during rescue situations is wise. In addition, paramedics must practice safe vehicle operation. They must use safety equipment and supplies as well.
- The misuse and abuse of drugs and other substances may lead to chemical dependency (addiction). This may have a wide range of effects on physical and mental health.
- The concept of diversity encompasses acceptance and respect of other people. It is important to realize that each person is unique and to recognize individual differences.
- "Good" stress is eustress. Eustress is a positive response to stimuli and is considered protective. "Bad" stress is distress. Distress is a negative response to environmental stimuli and is the source of anxiety and stress-related disorders.
- Adaptation is a process in which persons learn effective ways to deal with stressful situations. This dynamic process usually begins with using defense mechanisms. Next, one develops coping skills, followed by problem solving, and culminating in mastery.
- Critical incident stress management is designed to help emergency personnel understand their reactions to a call or event that had a major emotional impact. The process reassures them that what they are experiencing is normal and may be common to others involved in the incident.
- Often news of a sudden death must be given to a family. The paramedic's initial contact can influence the grief process greatly.
- The five stages of dying identified by Dr. Elisabeth Kübler-Ross are denial, anger, bargaining, depression, and acceptance.

CHAPTER

3 Injury Prevention and Public Health

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Identify roles of the emergency medical services community in injury prevention.
2. Describe the epidemiology of trauma in the United States.
3. Define injury.
4. Describe Haddon's matrix and the injury triangle.
5. Describe public health goals and activities.
6. Outline the aspects of the emergency medical services system that make it a desirable resource for involvement in public health activities.
7. Describe essential activities for the active participation of emergency medical services in community wellness activities.
8. List situations in which paramedics may participate in injury prevention.
9. Differentiate among primary, secondary, and tertiary health prevention activities.
10. Evaluate a situation to determine opportunities for injury prevention.
11. Identify resources necessary to conduct a community health assessment.
12. Relate how alterations in the epidemiological triangle can influence injury and disease patterns.
13. Describe strategies to implement a successful injury prevention program.

KEY TERMS

community health assessment An assessment of a target community to identify needs and resources required to provide prevention and wellness promotion activities.

epidemiology The study of the detriments of disease events in populations.

injury Intentional or unintentional damage to the person resulting from acute exposure to thermal, mechanical, electrical, or chemical energy or from the absence of essentials such as heat and oxygen

injury risk Real or potentially hazardous situations that put individuals at increased risk for sustaining an injury.

injury surveillance The ongoing systematic collection, analysis, and interpretation of injury data essential to the planning, implementation, and evaluation of public health practice.

primary injury prevention The practice of preventing an injury from occurring.

public health A field of medicine that deals with the physical and mental health of all people in a community.

secondary and tertiary prevention The care and rehabilitation activities,respectively, that are intended to prevent further problems from an event that has already occurred.

secondary injury prevention A concept that recognizes that injuries will occur and that is centered on reducing severity of the injury as it is occurring.

teachable moment The time after an injury has occurred when the patient and observers remain acutely aware of what has happened and may be more receptive to being taught ways that the event or illness could have been prevented.

years of productive life The calculation obtained by subtracting the age of teh victim's death from 65 (the average age of retirement)

A community has a duty to promote injury prevention. This prevention can occur in the form of leadership and educational activities. One goal of injury prevention is to decrease the incidence of preventable illness and injury. A final goal is to prevent persons from needing costly medical care. As a member of the health care system the paramedic can be a key resource in injury prevention programs (Box 3-1).

INJURY EPIDEMIOLOGY

Injuries that are unintentional are the leading cause of death among all persons 1 to 44 years of age. Unintentional injuries are the fifth leading cause of death among all age groups, exceeded only by heart disease, cancer, stroke, and chronic obstructive pulmonary disease.[1] In 2008, 118,000 injury-related deaths occurred in the United States.

Unintentional injuries result in more years of life lost before age 65 than any other cause of death. From a financial perspective the effect of fatal and nonfatal unintentional injuries was $652.1 billion in 2006. This equaled about $5700 per household (Figure 3-1). The quality of life lost from these injuries is valued at another $3080.1 billion. This makes the total cost $3732.2 billion in 2006[1] (Table 3-1). About 36% of all emergency department visits in the United States are related to injury. This percentage accounted for more than 41 million visits to emergency departments in 2005 (Box 3-1).

NOTE

While you make a 10-minute speech about bicycle safety to a classroom of children, at least 2 persons will be killed by unintentional injury. Another 498 will be disabled. A death caused by unintentional injury occurs in the United States every 4 minutes.[1]

OVERVIEW OF INJURY PREVENTION

Traditionally, emergency medical services (EMS) has been a reactionary medical discipline that waits until patients are injured or ill before being used. Reactionary medical care is termed *the acute care phase of injury control,* or *tertiary injury prevention*. Although EMS excels in acute care, a full system of injury control is made up of several facets, with acute care being one aspect. The injury control strategy of preventing rather than simply treating an injury is known as **primary injury prevention.**

Preventive strategies yield better outcomes than treatment strategies in terms of lives saved and money spent. Identifying prevention strategies relies heavily on data collection. Success also depends on teaching injury prevention to patients. Paramedics are respected in the community and generally are welcomed into homes and businesses. Thus paramedics have a unique opportunity to find injury patterns and intervene on behalf of persons at risk.

DID YOU KNOW?

The National Health Interview Survey

The National Health Interview Survey is conducted annually by the National Center for Health Statistics. This survey samples U.S. households to obtain data about the health status of household members. This includes any injuries that were sustained during the 5 weeks before the survey. In 2005 the survey found that most injuries (46.6%) occurred in or around the home. This was followed by injuries at recreational or sports facilities (14.2%) and then by injuries on streets, highways, and parking lots (13.3%).[2] It is this kind of data collection performed by various government agencies and health organizations (discussed later in this chapter) that guides the focus of injury prevention initiatives in this country.

Injury Concepts

DEFINITION OF INJURY

A puzzling factor that hindered the study of injury and therefore injury prevention was the apparent unrelated nature of injuries. On the surface, no relationship seemed

BOX 3-1 Injury and Illness Prevention Terminology

Injury: Intentional or unintentional damage to the person resulting from acute exposure to thermal, mechanical, electrical, or chemical energy or from the absence of essentials such as heat and oxygen

Injury risk: Real or potentially hazardous situations that put individuals at increased risk for sustaining an injury

Injury surveillance: The ongoing collection, analysis, and interpretation of injury data essential to the planning, implementation, and evaluation of public health practice; closely integrated with the timely dissemination of these data to those who need to know, with the final link in the chain being the application of these data to prevention and control

Primary injury prevention: The practice of preventing an injury from occurring

Secondary and tertiary prevention: The care and rehabilitation activities, respectively, that are intended to prevent further problems from an event that has already occurred

Teachable moment: The time after an injury has occurred when the patient and observers remain acutely aware of what has happened and may be more receptive to being taught ways that the event or illness could be prevented

Years of productive life: The calculation obtained by subtracting the age of the victim's death from 65 (the average age of retirement)

TABLE 3-1 Cost Equivalents, 2008

The Cost of	Is Equivalent to
All injuries ($701.9 billion)	62 cents of every dollar paid in federal personal income taxes, **or** 50 cents of every dollar spent on food in the United States
Motor vehicle crashes ($255.7 billion)	Purchasing 300 gallons of gasoline for each registered vehicle in the United States, or more than $1200 per licensed driver
Work injuries ($183 billion)	46 cents of every dollar of corporate dividend to stockholders, **or** 11 cents of every dollar of pretax corporate profits, **or** Exceeds the combined profits reported by the top 22 Fortune 500 companies
Home injuries ($182.3 billion)	A $222,600 rebate on each new single-family home built, **or** 45 cents of every dollar of property taxes paid
Public injuries ($103 billion)	A $11.2 million grant to each public library in the United States, **or** A $93,100 bonus for each police officer and firefighter

Courtesy National Safety Council: *Injury facts,* Itasca, Ill, 2010, The Council.

to exist between a vehicle crash and a poisoning, or between a gunshot wound and a drowning. However, it now is known that all injuries are the result of either (1) tissue damage caused by the transfer of energy to the human body (this energy may be mechanical, thermal, electrical, chemical, or radiant) or (2) tissue damage caused by the absence of needed energy elements such as heat or oxygen (see Chapter 37). So in essence, all injuries are related.

THE INJURY TRIANGLE AND HADDON'S MATRIX

Injury is also a disease process. Three factors are necessary to cause a disease: host, agent, and environment. Together these three factors are known as *the injury triangle* (Figure 3-2). In the injury triangle the host is the victim, the agent of injury is energy, and the environment provides a place for the agent and host to come together over time. The actual injury event may take only a fraction of a second, but the events that lead up to an injury and the events that occur as a result of an injury may take place over seconds, months, or even years.

NOTE
Changing one or more of the factors in the injury triangle can alter disease or injury patterns.

In the mid-1960s, William Haddon (the "father" of injury prevention) developed an analytical tool to aid in understanding the entire injury sequence. This tool is now known as *Haddon's matrix*. The three factors of the injury triangle are placed in a table on a timeline that is divided into three phases. These phases are preevent, event, and postevent. For example, the Haddon's matrix in Table 3-2 charts the events that may occur before, during, and after a car crash. The table helps one to see that injuries often result from a predictable and therefore preventable chain of events. The matrix also affirms that most injuries are linked with many causes.

The *preevent phase* is the period before the release of injury-causing energy. During this time the person's performance is greater than the task demands and energy is under control. Events in this phase tend to influence the *likelihood* that an injury will occur. Because the injury

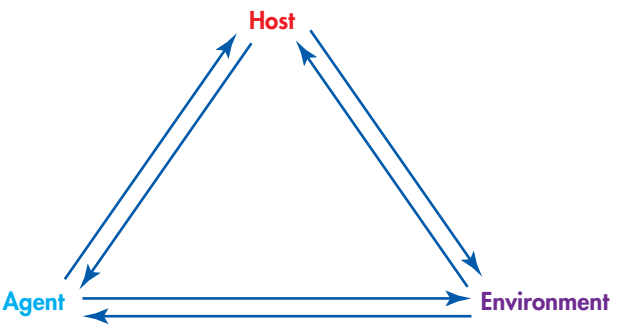

FIGURE 3-2 Epidemiological injury triangle.

TABLE 3-2 Haddon's Matrix for Automobile Crashes

	FACTOR		
Phase	**Host**	**Agent**	**Environment**
Preevent	Impaired capabilities, age, fatigue, alcohol/drug use, driving experience, adherence to driving laws	Defective equipment, dirty windows, improper maintenance, equipment design	Road shoulder too narrow, poor lighting, weather conditions, highway not divided, inadequate notification signs, road design, and construction
Event	Injury threshold caused by aging, chronic disease, alcohol, use of restraints, ejection	Failure of doors, impact with sharp objects in the vehicle, vehicle size	Lack of guardrails, large trees near roadside, oncoming traffic
Postevent	Type or extent of injury, knowledge of first aid, alcohol	Bursting gas tanks, entrapment	Quality of rescue, EMS, hospitals, rehabilitation

has yet to occur, primary injury prevention can take place in this phase. The time frame can be seconds to years, depending on what events come into play to cause the injury.

The *event phase* is the period during which the person's performance falls below the demands of the task. The result is the release of uncontrolled energy. The time frame usually is a fraction of a second to a few minutes. Events in this phase affect the transmission of energy. **Secondary injury prevention** recognizes that injuries are going to occur and is centered on reducing the severity of the injury as it is occurring.

The *postevent phase* is the period after the injury has occurred. This phase can last from a few seconds to years. In this time frame, tertiary injury prevention takes place and traditional EMS exists. The focus of tertiary injury prevention is to lessen the long-term adverse effects of the injury.

The Three E's of Injury Prevention

Three broad practices typically have been used to establish injury prevention programs. The first *E* of injury prevention is education. The second *E* is enforcement. The third *E* is engineering. A proactive, prevention-oriented paramedic can play a key role in all three strategies.

EDUCATION

The purpose of education is to persuade high-risk persons or groups to change risky behavior. It also is meant to teach these persons to adopt safety precautions. Education is considered an active countermeasure. This practice requires the person to do something to take advantage of knowledge learned and often requires the person to make a behavioral change. Education is the most often used approach in injury prevention. It is most effective when used with enforcement and engineering. Examples of educational programs include:

- Alcohol and other drug prevention
- Burn prevention
- Drowning prevention
- Elder safety
- Fall prevention
- Pedestrian and bicycle safety
- Poison prevention
- School safety and school-based programs
- Sports safety
- Suicide prevention
- Violence prevention

SHOW ME THE EVIDENCE

A North Carolina EMS service developed a program called "Welcome to the World." Paramedics trained in childhood injury prevention visited 110 families with newborns to provide home safety inspections. If hazards were identified they were corrected immediately or referred to another agency for correction. Paramedics also provided injury prevention education. They found that in families with one child 88% had smoke detectors, 64% had bath water <120° F, 94% had correct crib slat spacing, and 98% had a car seat. Only 38% of the homes with one child were deemed "infant-safe."

From Brice JH, Overby BA, Hawkins ER, et al: Determination of infant-safe homes in a community injury prevention program, *PEC* 10(3):397-402, 2006.

ENFORCEMENT

Enforcement occurs through force of law. It requires that persons adopt certain behaviors that reduce risk. Mandatory personal restraints (e.g., lap and shoulder restraints) and motorcycle helmet use laws are examples of this approach. Like education, enforcement is seen as an active countermeasure. It requires the person to adhere to the law to benefit from it, so the success of this approach depends on the compliance of individuals. Success also depends on the ability to enforce these laws. Even so, enforcement is more effective than education alone. Enforcement strategies that have been proven to reduce vehicle-related injury include:

- Child restraint laws
- "Click It or Ticket" programs

- Ignition interlock programs for repeat offenders
- Minimum legal drinking age laws
- Reducing legal blood alcohol concentrations
- Sobriety checkpoints and DUI enforcement
- Speed limit enforcement
- Zero tolerance for young drivers

ENGINEERING

Engineering refers to product or environmental design. This design automatically provides protection or decreases the likelihood that an injury-producing incident will occur. This approach builds safety into a product. Thus a person does not have to do anything to benefit from engineering. Engineering is a passive countermeasure. Examples include air bags in cars and sprinkler systems in buildings. Engineering has proved to be the most effective of the three *E*'s. However, engineering also is the most expensive approach to undertake. Examples of engineering used to prevent injury for paramedics include:

- Disposable equipment
- Latex gloves
- Needleless syringes and injection ports
- Nonslip footwear and nonskid surfaces
- Particulate air filters and masks
- Personal protective equipment
- Sharps containers

BASIC PRINCIPLES OF PUBLIC HEALTH

Most people know what is meant by the term *medical care*. And even though many people benefit from *public health,* they are less familiar with the term—specifically its missions and functions. Public health is different than medical care. Although there are many definitions of **public health**, the term can be defined as a field of medicine that deals with the physical and mental health of all people in a community. The focus of public health is more on prevention of disease than on treatment of disease. Important areas of public health include water supply, waste disposal, air pollution, and food safety. Other examples of public health goals and accomplishments include:

- Widespread vaccination programs
- Clean drinking water and sewage systems
- Declines in infectious disease
- Fluoridated water supplies
- Reduction in use of tobacco products
- Prenatal care services

Public Health Laws, Regulations, and Guidelines

Laws, regulations, and guidelines for public health initiatives are provided by local, state, and government agencies. Box 3-2 provides a sampling of state, federal, and international public health resources.

BOX 3-2 A Sampling of State, Federal, and International Public Health Resources

- Agency for Toxic Substances and Disease Registry (ATSDR)
- American Public Health Association (APHA)
- Association of Public Health Laboratories
- Association of Schools of Public Health (ASPH)
- Association of State and Territorial Health Officials (ASTHO)
- Centers for Disease Control and Prevention (CDC)
- Centers for Medicare & Medicaid Services (CMS)
- Food and Drug Administration (FDA)
- Health Resources and Services Administration (HRSA)
- National Academy of Sciences, Institute of Medicine (IOM)
- National Association of County and City Health Officials (NACCHO)
- National Association of Local Boards of Health (NALBOH)
- National Institutes of Health (NIH)
- National Organization of State Offices of Rural Health
- Public Health Foundation
- U.S. Department of Health and Human Services (DHHS)
- U.S. Environmental Protection Agency (EPA)
- World Health Organization (WHO)

Others involved in public health include medical professionals such as physicians, nurses, and EMS personnel. Area hospitals, clinics, public service agencies, and other government and nongovernment agencies also play important roles in providing public health services in a community.

FEASIBILITY OF EMERGENCY MEDICAL SERVICES INVOLVEMENT IN PUBLIC HEALTH

The United States has more than 840,669 EMS personnel.[3] As noted in *Emergency Medical Services: Agenda for the Future,* "People attracted to the EMS service are among society's best, and desire to contribute to their community's health. The composition of the EMS workforce reflects the diversity of the population it serves."[4] Thus it seems fitting that EMS plays a role in educating the public as a part of promoting health. EMS is a public health system and a workforce that is a valuable human resource. The following points support the feasibility of EMS interface with public health and injury prevention. EMS personnel are:

- Often the most medically educated persons in rural settings
- Role models with high profiles
- Seen as the champions of the customer
- Welcome in homes, schools, and other settings
- Seen as authorities on injury and prevention
- Often the first to note situations that pose a risk for illness or injury (e.g., unsanitary conditions and unsafe home environments)

CRITICAL THINKING

Did you ever have a class or program taught by a firefighter or paramedic when you were a child? How did you feel about the firefighter and paramedic?

NOTE

As managed care evolves, a demand on EMS for supportive care and intervention will increase. Paramedics and emergency medical services agencies must adapt to new roles in the health care delivery system.

Essential Community Leadership Activities

For paramedics and other public service personnel to play active roles in community health and injury prevention programs, the community must take the following steps to ensure successful participation among these groups (Box 3-3).

PROTECT EMERGENCY MEDICAL SERVICES PERSONNEL FROM INJURY

A basic first step for preventing injury and promoting wellness in a community is to protect the well-being of EMS personnel. Policies should help to ensure EMS safety during an emergency response, while at the scene, and during patient transportation. Protection can be accomplished with traffic safety laws and public education. Protection also can be enhanced with the help of law enforcement, fire service personnel, and other public service agencies.

All EMS workers must have access to personal protective equipment. This equipment helps to reduce the risk of eye, back, and skin injury. Other valuable safety tactics include helmets to reduce head injury, reflective clothing to increase visibility, and steel-toed shoes to prevent foot injury. Other goals of personal protection are to reduce exposure to communicable diseases and hazardous chemicals. Communities can reduce injuries related to work through personal safety programs. Communities also can reduce injuries by creating a wellness program for EMS workers (see Chapter 3).

BOX 3-3 Essential Community Leadership Activities

Communities have the responsibility to assist and support paramedics in the following activities:

- Protect the paramedic from injury.
- Provide primary injury prevention education to EMS personnel.
- Support and promote collection and use of injury data.
- Obtain support and resources for primary injury prevention activities.
- Empower individual paramedics to conduct primary injury prevention activities.

NOTE: Emergency medical services, through expanded scope of practice, will be performing these leadership activities for injury prevention and wellness.

PROVIDE EDUCATION TO EMERGENCY MEDICAL SERVICES PERSONNEL

Primary and continuing education programs for EMS personnel should include the basics of primary injury prevention. Community leaders should help to create a liaison between EMS programs and public and private specialty groups. These groups may include hospitals, other public health and safety agencies, safety councils, social services, religious organizations, colleges, and universities. This link will help provide specific education and training. Cooperation among these groups can help locate target groups for prevention activities and encourage sharing of program establishment tasks.

SUPPORT AND PROMOTE COLLECTION AND USE OF INJURY DATA

Communities should create policies that promote injury documentation by EMS personnel. Communities should review and at times modify the tools for data collection so that prompt recording of data is both feasible and realistic. The data collected should contribute to local, state, and national surveillance programs. For instance, these programs may include head and spinal cord injury registries, among others.

DID YOU KNOW?

Data Collection Registries

A registry (disease or trauma registry) is a file of uniform data. It describes persons who meet certain criteria. The registry collects medical and demographic data in an ongoing and systematic way to serve predetermined purposes.[5] These purposes include (1) facilitating and coordinating rehabilitation and other needed services, (2) gathering data for injury prevention and control, (3) gathering data for health care planning, and (4) evaluating services provided to injured persons.[6]

The first computerized trauma registry was introduced in 1969 at Cook County Hospital in Chicago, Illinois.[5] In 1985 the CDC began to promote the development of surveillance systems for clusters of injuries (sentinel injuries) at both the state and national levels. Since then, many states have developed statewide registries to track traumatic brain injuries, spinal cord injuries, and other classes of trauma. Federal agencies working with medical organizations and other groups help coordinate national-level standardizations of trauma registries. EMS and trauma care professionals play a major role in gathering these data. It helps in monitoring and evaluating the quality of trauma care in trauma center hospitals and trauma care systems.

OBTAIN SUPPORT AND RESOURCES FOR PRIMARY INJURY PREVENTION ACTIVITIES

The community needs to provide budgetary support for injury prevention programs. Community leaders may need to seek financial resources for fees and equipment,

publicity, and networking with other injury prevention organizations. In addition, the community needs to initiate or attend meetings of local organizations that are involved or that are requesting involvement in injury prevention. Grants can be obtained from state and national groups to help fund these initiatives. Examples of such organizations include the Centers for Disease Control and Prevention and Emergency Medical Services for Children. Grants may also be obtained from private donors, community block grants, and institutions. The funding may not always be easy to obtain. Regardless of how funding is obtained, EMS workers have a duty to provide prevention initiatives on any call where a preventable event has occurred.

EMPOWER INDIVIDUAL EMERGENCY MEDICAL SERVICES PERSONNEL TO CONDUCT PRIMARY INJURY PREVENTION ACTIVITIES

As stated previously, the community must financially support injury prevention programs. It must also promote interest and involvement in injury prevention activities from EMS personnel. This support can influence individual participation in the following ways:

- Providing rotating assignments to prevention programs
- Providing salary for off-duty injury prevention activities
- Rewarding and/or remunerating participation for on- and off-duty prevention activities

Essential Paramedic Activities

Activities that are essential for paramedics are based on education. These activities include knowing and practicing the personal injury prevention strategies. Examples of these strategies include:

- Appropriate use of audible and visual warning devices
- Availability and use of law enforcement
- Exercise and conditioning
- Practice of on-scene survival techniques
- Proper driving techniques
- Recognition of health hazards and high-profile crime areas
- Safety restraint use (self, patient, passenger)
- Secure equipment in patient care compartment
- Safe approach to parking at, and exiting, the scene
- Safe driving
- Scene safety precautions
- Stress management (personal, family, work)
- Traffic control (vehicles, bystanders)
- Use of on-scene survival resources
- Use of personal protective equipment (reflective clothing, helmets)
- Use of proper lifting and moving techniques
- Personal wellness

The paramedic also needs to know about illnesses and injuries common to various age groups and associated with different recreational activities, workplaces, and other facilities in the community (Box 3-4).

BOX 3-4 Other Essential Paramedic Activities

Other essential paramedic activities include review of illness and injuries common to the following:
Infancy (low birth weight; mortality and morbidity)
Childhood (intentional, unintentional, or alleged intentional events)
Childhood violence to self and others
Adults
Geriatric patients
Recreational activities
Workplace hazards
Day care centers (licensed and nonlicensed)
Early release from hospital
Discharge from urgent care or other outpatient facilities
Signs of emotional stress that can lead to intentional, unintentional, or alleged events
Self-medication
Dangers of noncompliance (borrowing, not taking medicines on time or finishing the regimen)
Storage of medicine
Overmedication and polypharmacy

SHOW ME THE EVIDENCE

Nationally registered EMS personnel were asked to describe their use of seat belts while in the front seat of the ambulance. "High" seat belt users had always worn their seat belts in the past year. "Low" seat belt users had never worn their seat belts in the past year. Those who worked in an EMS system with a seat belt policy were more likely to wear seat belts. Paramedics and EMS personnel who worked in rural areas were less likely to wear seat belts.

From Studneck JR, Ferketich A: Organizational policy and other factors associated with emergency medical technician seat belt use, *J Safety Res* 38(1):1-8, 2007.

Implementation and Prevention Strategies

In addition to the primary personal injury prevention strategies just listed, there are other key strategies. The paramedic needs to use these prevention strategies both for patient care considerations and to recognize the signs and symptoms of exposure to danger and the need for outside assistance. EMS personnel must document primary care and injury data as well. Finally, on-scene education is essential.

PATIENT CARE CONSIDERATIONS

The paramedic needs to identify signs and symptoms of suspected abuse and recognize potentially abusive situations. Such recognition helps to ensure the safety of the EMS crew and the patient (see Chapter 50). Preplanning for these events helps to identify outside resources that may play an important role in injury prevention. Examples include child protective services, abuse support groups, and rape/crisis intervention programs.

RECOGNITION OF DANGEROUS SITUATIONS

A priority for the paramedic is personal safety. Thus the EMS worker must stay alert for signs of dangerous situations. This includes recognizing general and specific environmental hazards. This will help the paramedic to assess a patient's need for preventive information. They will also help the paramedic assess a patient's need for direction. Examples include the following:

- Safety hazards in the home
- Inadequate housing conditions
- Inadequate food and clothing
- Absence of protective devices (e.g., smoke detectors)
- Hazardous materials (e.g., lead-based paint and dangerous chemicals)
- Communicable disease (and potential for transmission)
- Signs of abuse or neglect

CRITICAL THINKING

Do you know a paramedic who was injured on the job?How did the injury occur? Can you identify any measures that could have prevented it?

RECOGNITION OF THE NEED FOR OUTSIDE RESOURCES

Most communities have outside resources that can be helpful to their citizens. The providers of these resources and services are usually eager to assist with the development of injury prevention strategies. Such programs may be sponsored by municipal, community, and religious organizations. Box 3-5 provides a sampling of outside resources and services that are available in most communities.

DOCUMENTATION

Taking precise notes of patient care and primary injury data is crucial. This documentation offers a record of the events of the encounter. The notes are also helpful to others who will be taking part in the patient's care (see Chapter 4). Gathering primary injury data can be useful in designing injury prevention strategies. For example, one might study a large number of patients who received head injuries while riding a horse. This study may help one to observe that helmet use was notably absent in all seriously injured patients. Primary injury data include the following:

- Scene conditions
- Mechanism of injury
- Use of protective devices
- Absence of protective devices
- Risks at the scene
- Other factors as noted by the EMS agency

On-Scene Education

- The EMS response to an injury or near-injury may provide for a **teachable moment.** This is a moment in which the patient and the family may be open to injury prevention tips and strategies. The paramedic can use this opportunity to assess hazards in an environment. The paramedic also can provide on-scene, one-on-one injury prevention education. The teachable moment involves a three-step process[7]:
  1. *Observe the scene*: The first step is to look for contributing factors or hazards at the scene that may have caused or could cause an injury event. Examples include floor rugs without a nonslip backing and inoperable smoke detectors.
  2. *Gather information:* The next step is to gather information from individuals and observers. What did they see? Why do they think the injury occurred? Has this been a common occurrence? Patients, family members or bystanders, and first responders may have valuable insight about a situation that caused an injury event.
  3. *Make assessments:* The final step is to make decisions from the information that has been gathered. The first assessment is to decide whether the situation is critical or noncritical. If the situation is critical, the focus must be on patient care. If the situation is noncritical, a teachable moment exists. This is the opportunity to conduct one-on-one injury prevention counseling that may help to prevent another injury. Another assessment uses the information gathered through observation and history taking.

BOX 3-5 Sampling of Outside Resources and Services

Municipal
Animal control services
Child protective services
Fire service personnel
Law enforcement personnel
Social services

Community
Abuse support groups for spouses, children, and older adults
Alternative health care services (e.g., free clinics)
Alternative means of transportation
Alternative modes of education
Assistance for food, shelter, and clothing
Day care services
Disaster services (e.g., American Red Cross)
Immunization programs
Managed care organizations
Mental health resources and counseling
Rape or crisis intervention
Rehabilitation programs
Services for the disabled
Work-study programs

Religious
Family counseling
Grief support
Pastoral services
Support groups

The paramedic uses this step to decide whether high-risk persons, high-risk behaviors, or a high-risk setting exists. Based on the assessment of risks, the paramedic can create a remedy.

Three common on-scene remedies are *discussion, demonstration,* and *documentation*. Discussion involves talking about proper behavior or action with the person at risk. Injury prevention discussions are a 30- to 60-second process. The message must be offered in a patient-appropriate manner. This manner depends on age, education, and socioeconomic status. The message should be conveyed in a nonjudgmental, "here are the facts" tone of voice. Although discussion may not always work, the paramedic should attempt it.

It may be possible to demonstrate proper behavior as an injury prevention strategy. For example, the paramedic could replace a safety cap on a pill bottle and explain the importance of doing so. The paramedic could put a fresh battery in a smoke detector. Or the paramedic could move a throw rug on a slippery floor to a safer location. These demonstrations on the scene draw attention to likely hazards and can help prevent future injury.

The paramedic should document what was seen, heard, and done at the scene. Written histories allow for follow-up by the receiving personnel. Other injury prevention groups also can use these histories in their data-gathering efforts. Lastly, histories make it easier for review in the EMS organization to improve injury prevention.

Other Injury Prevention Roles in Emergency Medical Services

In addition to the injury prevention strategies just listed, EMS personnel can play a major role in improving public health and safety. They can do this through support of legislative change and through involvement in primary prevention programs. Box 3-6 lists a sampling of these other injury prevention roles.

CRITICAL THINKING

At some point, you probably will visit an older adult family member or friend. Can you identify any potential hazards that exist in that person's home?

PARTICIPATION IN PREVENTION PROGRAMS

Prevention programs that are effective first call for a **community health assessment.** This assessment is needed before the intervention can take place. The assessment also is required before the education can begin. A systematic approach to a health assessment and prevention programs includes the following steps (Figure 3-3):

1. Gather information and identify the problem and population.
2. Identify prevention strategies.
3. Choose the best strategy.
4. Develop the plan.
5. Implement the plan.
6. Evaluate and revise the plan as needed.

Community Health Assessment

Paramedics may likely have limited time and resources to allot to prevention and wellness promotion. To maximize available time and resources, paramedics can perform a community health assessment to identify the target for community health education (Figure 3-4).

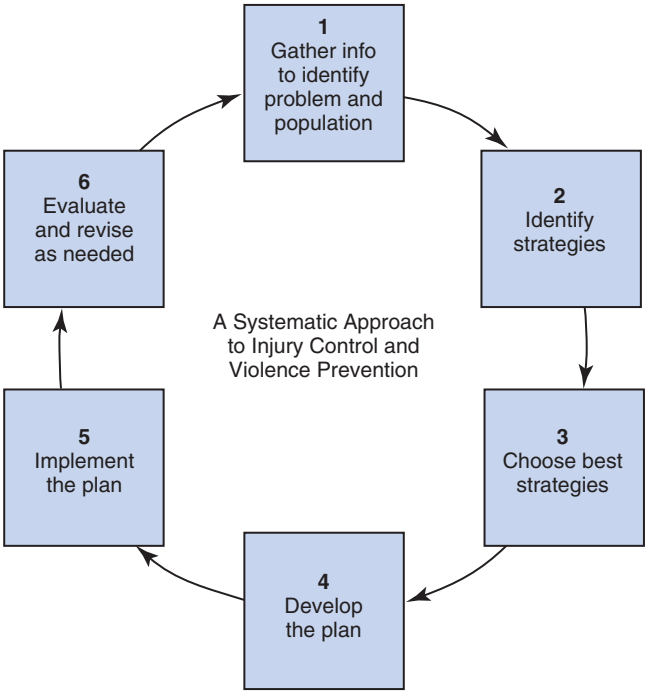

FIGURE 3-3 A systematic approach to health assessment and injury prevention programs.

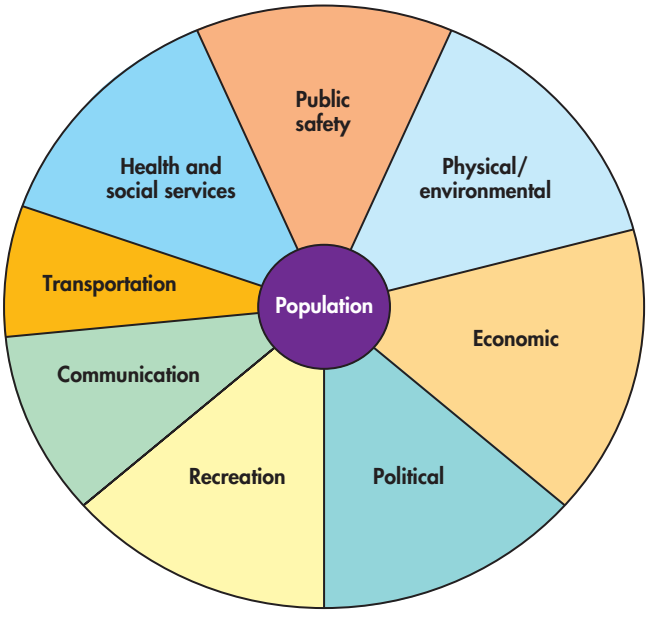

FIGURE 3-4 Community health assessment.

BOX 3-6 A Sampling of Injury Prevention Strategies*

Bicycle Safety
Bicycle helmet programs

Brain Injury
Brain injury prevention programs

Burns
Fire prevention programs
Smoke detector programs

Children
Babysitter training classes
Child abuse prevention programs
Child safety seat programs
Child safety programs
Drowning prevention programs
Emergency medical services for children (EMSC) programs
Parenting classes
Playground safety programs
Safe kids programs
Safe school programs
Swimming classes
Youth advocacy groups

Community Safety
Safe communities programs

Elderly
Programs to reduce elderly falls

Firearm Safety
Gun safety programs

Home Safety
Home assessment programs

Legal/Political
Being involved as an expert or advisor in the political process during the debate over laws dealing with the following:

- Child and adolescent safety laws
- Drunk driving laws
- Engineering regulations (building safety into a product)
- Gun legislation
- Helmet laws

Many Internet sites have information on ways to prevent medical illness. Some of this material can be passed on to the paramedic's patients. The information can be provided informally or through a program with handouts or public service activities. Sites include the following:

- Acquired immunodeficiency syndrome
- Cancer
- Cardiovascular health
- Childhood illnesses
- Influenza
- Healthful lifestyle
- Heat-related illness
- Medical conditions A to Z (Centers for Disease Control and Prevention site)
- Parenting
- Premenstrual syndrome
- Senior citizen illnesses
- Stroke

Most local physician offices have brochures that EMS personnel can hand out in cooperation with the local doctor.

Neurological Injury
Head injury prevention programs

Nutrition
Proper nutrition programs

Occupational Safety
Occupational illness and injury prevention programs

Pedestrian Safety
Pedestrian safety programs

Poisoning
National Poisoning Prevention Week

Posttraumatic Stress Syndrome
Programs for the community
Programs for EMS and other public safety personnel

Public Driving
Programs to prevent driving while intoxicated
Programs to prevent running of red lights
Programs to promote seat belt use

Rehabilitation
Rehabilitation support groups

Research
Universities throughout the United States research many illness and injury prevention strategies. These schools often welcome input from EMS personnel. This input may be in the form of volunteer work in data collection. Input also may be ride-alongs by the researchers. Input can even help in the actual writing of the research documents. Emergency medical services personnel should search for injury prevention centers, illness prevention centers, EMS research centers, and schools of public health within colleges and universities in their local area.

Smoking
Smoking cessation programs

Substance Abuse
Addiction programs
Substance abuse prevention programs
Substance abuse prevention programs for youth

Suicide
Suicide prevention programs

Trauma
National Trauma Awareness Week

Violence
Violence prevention programs
Violence survivor programs

This list is compiled from programs already in place. Some of these are national and some are local. The student should seek those programs that already exist in his or her area. If a program does not exist locally, chances are it exists somewhere in the United States. If interested, the student should search the Internet or other sources and find a comparable guide for starting a local program.

*This box should encourage the paramedic student to search for prevention programs that are of personal interest because the work likely will be voluntary and without pay.

This assessment often is a large undertaking and may be conducted more effectively through a group effort with other health agencies to evaluate the following:

- Population demographics
- Morbidity statistics
- Mortality statistics
- Crime and fire information
- Community resource allocation
- Hospital data (e.g., emergency department visits and length of stay)
- Senior citizen needs
- Education standards
- Recreational facilities
- Environmental conditions
- Other factors

NOTE

Morbidity statistics refers to the disease rate of a population or geographic region. *Mortality statistics* refer to the number of deaths per unit of population in a specific region or for a specific age group, disease, or other classification. This number is usually expressed as deaths per 1000, 10,000, or 100,000 (see Chapter 8).

This "landscape" view of the health of a community can yield data that are valuable, and sometimes unexpected, about the target population. The assessment also can identify factors that relate or contribute to certain health risks. After the assessment the paramedic should choose the target for health education carefully and then use a fitting intervention. Ideally, the paramedic should compare the data from the assessment with those of another population (Box 3-7). This population should have similar demographics. For example, a city of similar size within the state would be a good choice.

Community Health Intervention

After identifying a health risk, the paramedic must implement a plan that attempts to reduce or eradicate the risk. This plan also should attempt to help improve the health of the community. The three levels of health prevention activities are *primary, secondary,* and *tertiary*. Primary prevention prevents problems and disease development before they occur. Examples include seat belt education, laws requiring wearing of helmets while bicycling, and vaccination programs. Secondary prevention activities find issues and promote early intervention. They also prevent complications and/or progression of disease. For example, health screenings to detect hypertension is a secondary prevention activity. Tertiary prevention activities correct and prevent further deterioration of a disease or problem. An example of this is providing EMS services in a community. The three types of prevention activities often overlap. Box 3-8 provides examples of each activity.[8]

BOX 3-7 Sampling of Community Health Information Sources

American Heart Association
American Red Cross
Births and deaths (including cause)
Call types and response times
Census data (public library, Internet)
Centers for Disease Control and Prevention
Chamber of Commerce
Clustering of illnesses and injuries
Communication
Crime rate statistics
Disaster planning
Distribution of age, sex, race, ethnicity
Distribution of grant monies
Education and literacy rates
Emergency coordinating council
Emergency medical services
Employment statistics
Environmental hazards (sanitation, air quality)
Federal Emergency Management Agency (FEMA)
Federal government
Fire service
Fire-related injuries and fatalities
Form of government
Geographic distribution
Health departments (city, county, state, Internet)
Health services and school lunch programs
Hospitals
Housing and tax information
Industry and economic figures
Infectious disease statistics
Law enforcement
Local government
Location and frequency of fires
National Safety Council
Newspapers, radio, and television stations
Parks and recreation
Population demographics
Religious organizations
Response times
School board
Socioeconomic status
State trauma registry statistics

Community Health Education

A good injury prevention program must serve the entire target population in a community. This also is the mark of a successful program. The community must try to improve the education and training for EMS and other public service agencies. In that way special groups can be included in the prevention program. Examples include training emergency personnel to communicate effectively with the following:

- Various ethnic, cultural, and religious groups
- Non–English-speaking populations
- Those with learning disabilities
- Those who are physically challenged

DID YOU KNOW?

Immunization Programs

Paramedics are trained to administer medications and can play a vital role in immunization programs in a community. Numerous studies have demonstrated the feasibility of EMS agencies in administering vaccines. The programs followed CDC guidelines[9] and were performed under strict medical oversight. Citizens were recruited through public service campaigns to visit EMS stations, places of worship, retail establishments, and other public places to receive the vaccine. It was found that paramedics can safely provide immunizations and can sometimes reach populations who otherwise would not have received the medication.[10]

In the event of a pandemic disease outbreak or other disease emergency requiring large-scale vaccination, it is likely that paramedics will provide vaccines and antiviral drugs at emergency dispensing sites (EDSs) in the community.[11,12] (See Chapter 28 and Chapter 58 for more discussion.)

CRITICAL THINKING

What method of health education is most likely to change your personal behaviors? Would that same method be equally effective for a 5-year-old or a 70-year-old person?

The paramedic must consider the reading level and age of the target population. Recognizing these considerations helps the paramedic prepare educational materials and make the materials more effective. Before starting any type of large-scale educational program, the paramedic should test the program on a target audience. This test will evaluate the appeal of the materials and ensure understanding of the message. EMS personnel can provide community health education to promote wellness and injury prevention in numerous ways, including the following:

BOX 3-8 Examples of Prevention Activities

Primary Prevention Activities

Influenza/pneumococcal immunization
Smoking cessation
Preventive dental care
Car seat distribution and installation

Secondary Prevention Activities

General health screenings
Colonoscopy
Mammography
Blood pressure screenings

Tertiary Prevention Activities

Lowering cholesterol after myocardial infarction (MI)
Treating hypertension after stroke
Providing exams for eye and foot problems in diabetic patients

Verbal

- Lectures
- Informal discussions
- Informal teaching on an EMS call
- Podcasts
- Radio programs

Written/static visual

- Bulletin boards, exhibits
- Flyers, pamphlets, posters
- Models
- Slides, photographs

Dynamic visual

- Videotapes
- Television
- Internet resources (blogs, websites)

SUMMARY

- Emergency medical services personnel are members of the community health care system. They can be an important resource in injury prevention.
- Unintentional injuries are the fifth leading cause of death. This cause is exceeded only by heart disease, cancer, stroke, and chronic obstructive pulmonary disease.
- The United States has more than 800,000 EMS personnel. This valuable human resource plays a major role in public education. This component of health promotion seems only fitting.
- It is crucial that paramedics play an active role in the health of a community. Thus the community must protect the EMS worker from injury. The community also needs to provide education to paramedics. The community should supply support and promote the collection and use of injury data as well. In addition, the community must obtain resources for primary injury prevention activities. Lastly, the community needs to empower paramedics to conduct primary injury prevention.
- Paramedics must have a basic knowledge of personal injury prevention. They also should know about maladies and injuries common to various age groups and associated with different recreational activities, workplaces, and other facilities in the community.
- The paramedic needs to note the signs and symptoms of abuse and abusive situations. In addition, the paramedic should notice exposure to danger.

Continued

- Paramedics should identify and use outside community resources. Plus they should document primary injury data properly. Moreover, they should identify and properly use the teachable moment.
- The paramedic must maximize time and resources. Thus the paramedic should identify targets for community health education. The paramedic can do this by performing a community health assessment.
- To identify community education goals, the paramedic must understand several factors: (1) illness or injury is related to the extent or exposure to an agent; (2) illness or injury also is related to the strength of the agent; (3) illness or injury is linked to the susceptibility of the individual (host); and (4) illness or injury is related to the biological, social, and physical environment.
- Primary injury prevention involves preventing an injury from occurring. Secondary and tertiary prevention help to prevent further problems from an event that has already occurred.
- A good injury prevention program must serve the whole target population in a community. An effective program also takes into account reading level and age. These aspects are the mark of a successful program. The paramedic can provide community health education in diverse ways, including verbal, written/static material, and dynamic visual presentations.

CHAPTER

4 Documentation

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Identify the purpose of the patient care report.
2. Describe the uses of the patient care report.
3. Outline the components of an accurate, thorough patient care report.
4. Describe the elements of a properly written emergency medical services (EMS) document.
5. Describe an effective system for documenting the narrative section of a prehospital patient care report.
6. Identify important differences in the documentation of special situations.
7. Describe the appropriate method for revising or correcting the patient care report.
8. Recognize consequences that may result from inappropriate documentation.

KEY TERMS

military time A precise method of expressing time that is used by the armed forces and is based on a 24-hour clock.

narrative The portion of the patient care report that presents a chronological description of the call.

objective information Information based on observable facts, such as clinical signs or symptoms.

patient care report A document used in the prehospital setting to record all patient care activities and circumstances related to an emergency response.

pertinent negative findings Findings that warrant no medical care or intervention but that provide evidence of the thoroughness of the patient examination and the history of the event.

pertinent oral statements Statements made by the patient and other individuals at the scene.

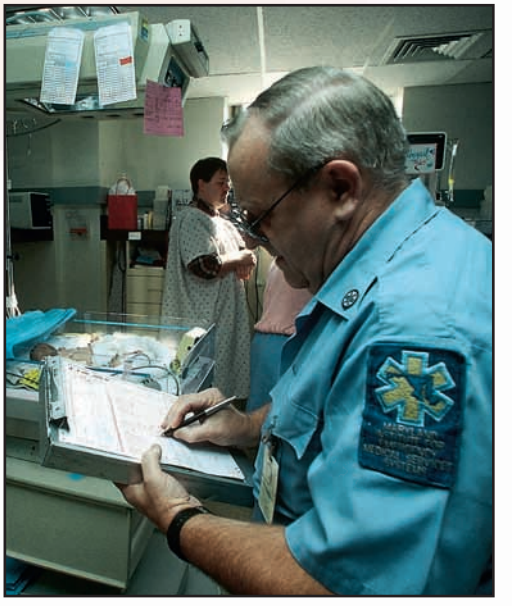
pertinent positive findings Signs or symptoms that help substantiate the patient's condition.

subjective information Information based on opinions expressed by patients or others.

*The **patient care report** is used to document the essential elements of patient assessment, care, and transport. It is a legal document, and next to providing good patient care, it is the paramedic's best protection from liability action.*

IMPORTANCE OF DOCUMENTATION

Thorough written documentation is important for many reasons (Box 4-1). It provides a tangible and legal record of an incident. It often is used by physicians, nurses, and others involved in the patient's care. Hospital staff members read the patient care report (PCR) to understand the patient's initial condition and the type of care given in the field. The EMS agency and medical direction may use the PCR to monitor care in the field, evaluate an individual paramedic's performance, and conduct review conferences and other educational forums. The four main reasons for charting patient care[2] are to:



(Courtesy Maryland Institute for Emergency Medical Services Systems and Acadian Ambulance Service, Baltimore.)

BOX 4-1 Advantages of Written Documentation

Written documentation provides for:

- A tangible record of the incident
- A legal record of the incident
- Professionalism
- Medical audit
- Quality improvement
- Billing and administration information
- Data collection

- Demonstrate the continuity of the patient care provided
- Create a legal record of the patient care provided
- Assist in financial reimbursement and cost recovery for patient care services and equipment and supplies
- Assist in quality improvement studies and EMS research

NOTE

The requirements for retaining medical records vary throughout the United States. Most medical records (including patient care reports) are maintained for at least 10 years.[1] These records are kept as a safety measure in case legal action involving a statute of limitations arises. *Thorough documentation is essential. It leads to accurate recall if litigation occurs.*

Data collection and recordkeeping are important for identifying quality improvement issues (see Chapter 1). Such issues that may be identified through the PCR, resulting in policy changes to improve patient care, include:

- Minimizing the time spent at the scene with critical trauma patients
- Adding new medications to better manage some medical emergencies
- Changing the placement of emergency vehicles during peak response times in certain demographic areas

The PCR also documents any unique scene situations that may have affected patient care. For example, traffic may have caused a long response time. A trapped patient may have required prolonged extrication. The PCR also helps track certain patient care skills of the paramedic (e.g., insertion of intravenous lines, intubation, and defibrillation). The EMS agency's training division may require tracking of these skills. In some states, documentation of advanced life support (ALS) skills may be required for relicensure or recertification.

GENERAL CONSIDERATIONS

The PCR should be legible and carefully detailed (Figure 4-1). It is a legal document and part of the patient's medical record. Therefore, slang terms and medical abbreviations that are not universally accepted should not be used. Common medical abbreviations and symbols used in EMS documentation are presented in Chapter 9.

BOX 4-2 Military Time Chart

Most EMS agencies and patient care facilities use military time to chart patient care activities and to note other entries in the patient care record. Military time uses a 24-hour clock, which makes notation of AM or PM unnecessary. It is considered a precise method of expressing time. Military time begins at midnight (0000).

Regular Time	Military Time	Regular Time	Military Time
Midnight	0000	Noon	1200
1:00 AM	0100	1:00 PM	1300
2:00 AM	0200	2:00 PM	1400
3:00 AM	0300	3:00 PM	1500
4:00 AM	0400	4:00 PM	1600
5:00 AM	0500	5:00 PM	1700
6:00 AM	0600	6:00 PM	1800
7:00 AM	0700	7:00 PM	1900
8:00 AM	0800	8:00 PM	2000
9:00 AM	0900	9:00 PM	2100
10:00 AM	1000	10:00 PM	2200
11:00 AM	1100	11:00 PM	2300

BOX 4-3 Data Included in the Patient Care Report

- Dates
- Response times
- Difficulties en route
- Communication difficulties
- Scene observations
- Reasons for extended on-scene time
- Previous care provided
- Time of extrication
- Time of patient transport
- Reason for hospital selection (trauma center designation, patient choice, or other concerns)

The report should include all dates and response times, noted in **military time** (Box 4-2). In addition, any difficulties encountered en route or during patient treatment, extrication, or transport should be described. The report also should include observations at the scene, any previous medical care provided (and by whom), and the time of patient extrication, if appropriate (Box 4-3). The times of all significant occurrences and interventions are useful to the receiving physician and should be recorded. In particular, the PCR provides a legal and accurate recording of the following incident times:

- Time of the call
- Time of dispatch
- Time of arrival at the scene
- Time at patient's side
- Time of vital signs assessments

NOTE

The National EMS Information System (NEMSIS) has developed an EMS Dataset Schema.[3] This is a comprehensive list of all potential elements of information that would be collected about an emergency incident. It includes information that would be considered important from the perspectives of an EMS system, EMS personnel, and an EMS patient. The data elements in the EMS dataset provide documentation of the system performance and clinical care. The purpose of the Dataset Schema is to create a national EMS database that contains information from local and state EMS agencies across the nation. To date, 48 states and three territory members have agreed to participate and to support the EMS data initiatives set by NEMSIS.

SHOW ME THE EVIDENCE

In one study, researchers compared the times used to record medical information in five hospitals and three EMS systems in Indianapolis, Indiana. They compared the times of clocks in these systems to the Coordinated Universal Time (UTC) kept by an atomic clock in Boulder, Colorado. The 152 clocks included in the study showed an average difference from UTC of 1 minute and 45 seconds. The differences ranged from 12 minutes and 34 seconds slow to 7 minutes and 7 seconds fast. The researchers concluded that the time sources studied varied considerably in their ability to keep accurate time.

Cordell WH, Olinger ML, Kozak PA, Nyhuis AW: Does anybody really know what time it is? Does anybody really care? *Ann Emerg Med* 23:1032-1036, 1994.

When testimony must be given years after an incident, the PCR may be the only means by which a paramedic can recall accurately the events of an emergency call. Paramedics must include as much detail as possible in the PCR, because this level of detail is useful both for present and for future use (see Chapter 6).

CRITICAL THINKING

Documentation of specific times on the PCR is important. How can this information be useful?

THE NARRATIVE

The **narrative** section of the PCR provides a chronological account of the call. Paramedics should write the narrative concisely and clearly, using simple words. They should not use uncommon abbreviations or unnecessary terms or include duplicate information. A standard format established by medical direction can help ensure completeness. Such a format also aids quality improvement reviews. Components of the narrative of the PCR include the following:

- Initial contact
- All patient care activities (including medications and treatments; also, care provided by others at the scene)
- Initial assessment and vital signs
- Chief complaint
- Pertinent significant medical history
- Clock time of hospital contact
- Time of physician's orders and advice (name of physician)
- Pertinent positive and negative findings
- Pertinent oral statements
- Changes in the patient's status
- Patient's response to treatment
- Vital sign reassessment
- Electrocardiogram (ECG) interpretation
- Diagnostic readings (e.g., capnography, pulse oximetry, serum glucose)
- Use of support services
- Time of delivery to health care facility and patient's condition
- Name of receiving health care worker
- Signature of paramedic

NOTE

Paramedics should never use documentation to creatively reconstruct patient care. If the paramedic did not document the care, it was not done. Conversely, if the care was not done, the paramedic should not document it.

SHOW ME THE EVIDENCE

Salt Lake City researchers compared PCRs produced after implementation of a quality improvement (QI) program that provided feedback on documentation with documentation done before the program was initiated. They found that with the QI program, documentation in the PCRs improved in 13 of the 19 parameters evaluated. These researchers concluded that a QI program can improve documentation in an EMS system.

Joyce SM, Dutkowski KL, Hynes T: Efficacy of an EMS quality improvement program in improving documentation and performance, *Prehosp Emerg Care* 1:140-144, 1997.

Pertinent findings may be classified as positive or negative. Both types should be documented in the PCR, because both can help determine the course of treatment. **Pertinent positive findings** are signs or symptoms that help substantiate the patient's condition. Examples of positive findings include difficulty breathing, numbness or paralysis, and altered mental status. **Pertinent negative findings** are findings that warrant no medical care or intervention but that show the thoroughness of the paramedic's examination of the patient and the history of the event. Examples

of negative findings include the absence of diminished breath sounds, the absence of skin rashes, and the absence of abdominal tenderness. **Pertinent oral statements** are those made by the patient and other individuals on the scene. These statements should also be recorded. Statements that may have an impact on patient care or resolution of the situation include the following:

- Mechanism of injury
- Patient's behavior
- Aid given before arrival of EMS
- Safety-related information (including disposition of weapons)
- Information of interest to crime scene investigators
- Disposition of valuable personal property (e.g., jewelry and wallets)

The paramedic should enclose in quotation marks any statements made directly by patients or others that relate to possible criminal activity. In addition, an admission of suicidal intention should be recorded in quotes.

Failed skills should be documented in the PCR, such as unsuccessful attempts to start an intravenous line or to perform endotracheal intubation. The narrative also should include the use of support services and mutual aid assistance (e.g., helicopter, coroner, rescue or extrication team). As the last step, the paramedic should sign the PCR.

CRITICAL THINKING
Why should you note the previous care given by bystanders in your report?

The PCR should list everyone who took part in the patient's care before delivery to the emergency department (ED). Because a copy of the report is placed in the patient's hospital medical record, paramedics may need to leave a finished copy at the receiving hospital. This means that the report must be completed in a timely fashion at the receiving hospital so that the EMS crew can be available for another call. If possible, the report should be left with the patient at the hospital.

NOTE
Even electronic reports that allow automatic selections require a narrative. Details such as the patient's appearance, the individual's home or vehicle, the mechanism of injury, and specific statements made by the patient often are not included in an electronic report if a narrative is not written.

ELEMENTS OF A PROPERLY WRITTEN EMS DOCUMENT

A properly written EMS document is accurate and complete, legible, timely, unaltered, and free of nonprofessional or extraneous information.

1. *Accurate and complete*. All relevant information must be provided in the narrative and check-box sections of the report; this ensures accuracy. Completion of all areas of the report (even a section that was unused) is the sign of a precise, full document. The paramedic should make sure medical terms, abbreviations, and acronyms are used properly and spelled correctly.
2. *Legible*. All writing, especially in the narrative, must be easily read by others. Check-box markings should be clear and consistent from the top page of the report to all underlying pages.
3. *Timely*. Ideally, the documentation is completed immediately after the paramedic completes the patient care. Delays in recording can result in serious omissions, which may be interpreted as negligent patient care.
4. *Unaltered*. If an error is made during documentation, the paramedic should draw a single line through the error and then date and initial the error (Figure 4-2). Any changes to a completed report should be accompanied by a proper "revision/correction" supplement with the date and time of revision.
5. *Free of nonprofessional and extraneous information*. The PCR must be free of jargon, slang, personal bias, libelous or slanderous remarks, and irrelevant opinions or impressions.

NOTE
An EMS report should be considered confidential. Paramedics must comply with all patient privacy provisions as outlined by the policies of their agency and by the Health Insurance Portability and Accountability Act (HIPAA) (see Chapter 6).

These same five principles of documentation apply to computer-generated PCRs (Figure 4-3) and other computer-generated forms. Other, related documentation (e.g., ECG

FIGURE 4-2 Correction of a patient care report.

FIGURE 4-3 Paramedic completing an electronic patient care report. (Courtesy Grande Prairie Regional EMS, Alberta, Canada.)

or capnography tracings, photographs, insurance information) should be properly labeled and attached, scanned, or uploaded with the report.

SYSTEMS OF NARRATIVE WRITING

As with all other aspects of emergency care, paramedics should develop a systematic approach to writing the PCR narrative. Many approaches can be used for this purpose. However, the best practice is to adopt only *one* approach and to use it consistently; this helps prevent omissions in report writing. Regardless of the system used, the paramedic must make sure that **objective information,** rather than **subjective information,** is the focus of the report.

NOTE

Objective information is supported by facts and direct observation (e.g., an obvious fracture). *Subjective information* cannot be supported by facts (e.g., the patient appears depressed). When including subjective information in the narrative, the paramedic should enter the patient's own words, enclosed within quotation marks. Some subjective observations should be documented carefully and reported to medical direction, such as behavior by a child that may indicate physical or sexual abuse in the home.

Formats that have been established to organize the narrative include the SAMPLE history; the SOAP format; the CHART format; and the CHEATED charting method.

- The elements of the *SAMPLE history* are signs and symptoms *(S)*, allergies *(A),* medications *(M),* past medical history *(P),* last meal or oral intake *(L),* and events before the emergency *(E)*. (The patient history is presented in detail in Chapter 18.)
- The *SOAP format* can be used to organize a patient report for most patient care encounters. The elements of this format are:
  - *S*ubjective data: All of the patient's symptoms, including the chief complaint, associated symptoms, history, current medications, and allergies, in addition to information provided by the patient, bystanders, and family.
  - *O*bjective data: Pertinent physical examination information, including vital signs, level of consciousness, physical examination findings, ECG data, pulse oximetry readings, and blood glucose determinations.
  - *A*ssessment data: The paramedic's clinical impression of the patient based on subjective and objective data.
  - *P*lan of patient management: Treatment that has been provided and any requests for additional treatment.
- The *CHART format* is an alternative to the SAMPLE and SOAP methods. It includes the following elements:
  - Chief complaint: The patient's primary complaint.
  - *H*istory: The history of the current illness; any significant medical history; the patient's current health status; and a review of systems.
  - *A*ssessment: The paramedic's general impression; vital signs; physical examination findings; diagnostic tests; and field diagnosis.
  - *Rx* (treatment): Standing orders or protocols; direct orders from online medical direction.
  - *T*ransport: Effects of interventions; mode of transportation; ongoing assessment findings.
- The *CHEATED charting method* begins with the initial patient contact and ends when the patient is delivered to the ED. The elements are:
  - Chief complaint: The reason the patient requested EMS assistance.
  - *H*istory: Past and present medical history, nature of incident, mechanism of injury.
  - *E*xamination: The physical assessment.
  - *A*ssessment: General impression and diagnosis.
  - *T*reatment: Any care rendered.
  - *E*valuation: Patient's response to care provided (improvement or deterioration).
  - *D*isposition: The transfer of patient care to another health care professional.

Other approaches also may be used to write the narrative. These include the head-to-toe physical approach; a review of primary body systems approach; a chronological, call-incident approach; and a patient management approach.

The *head-to-toe physical approach* often is used in the PCR narrative. Paramedics may use this approach to record their findings after performing a full head-to-toe physical examination. Findings are noted in the narrative in the same order as they occurred in the examination. For example, findings from the examination of the patient's head are noted first (e.g., pupillary response). The paramedic ends by noting circulatory findings (e.g., the character of a pedal pulse or capillary refill) from the examination of the patient's extremities.

A *review of primary body systems approach* may be used when the examination is performed for a chief complaint that focuses on one body system. For example, for chest pain with suspected myocardial infarction, the paramedic would limit the findings to the cardiorespiratory system. Findings may include a description of the patient's pain, vital signs, ECG findings, associated breathing difficulties, significant medical history, allergies, and medication use.

The *chronological, call-incident approach* begins by noting the time of arrival at the patient's side and the initial examination findings, the time of vital sign assessment and reassessment, and a chronological listing of all patient care interventions performed at the scene and en route to the ED. This type of report commonly is used to document the events involving a patient with major trauma who has extended on-scene time. This format also may be used during a cardiac arrest event when numerous medications and electrical therapy are administered.

The *patient management approach* is used to organize and record the complete patient management plan. The report covers the emergency response from start to finish. This approach might describe in detail how the patient was found, what interventions were performed and why, and any important assessment findings. The patient management approach differs slightly from the others described in that it provides a more complete picture of the events at the scene, during care, and during transport of the patient.

CRITICAL THINKING

How many meanings can you think of for the word *lethargic*? Look it up in the dictionary. Should you use this word to document a patient's mental status? Why?

SPECIAL CONSIDERATIONS IN DOCUMENTATION

Several considerations in the documentation of patient care deserve special mention. Some of these include a patient's refusal of care or transport, situations and events in which transportation is not needed, interagency and interfacility transfers, mass casualty situations, and exposure or injury reporting. Other special situations (e.g., legal reporting, caring for intoxicated patients, and cases of abuse and neglect) are discussed in Chapters 6 and 51.

Patient's Refusal of Care or Transport

A patient's refusal of care or transport is a major area of potential liability for paramedics and EMS agencies (see Chapter 6). Thorough documentation of these situations is crucial and should include the following:

- The physical assessment findings
- The paramedic's advice to the patient about the benefits of treatment and the risks associated with refusing care
- The advice provided by medical direction by telephone or radio
- Clinical information that suggests the patient is able to make heath care decisions (e.g., the individual's level of consciousness)
- The signatures of any witnesses to the event, according to local protocol
- A complete narrative, including quotations or statements made by others

If the patient refuses care or transport, the paramedic should document the incident in exacting detail (Figure

REFUSAL OF MEDICAL CARE

I hereby voluntarily acknowledge and state that I have been advised regarding the state of my present physical condition. I have been advised of the risks/complications of my condition and the dangers of refusing medical treatment. I understand the risks, complications and/or dangers of refusing medical treatment as explained by St. Charles County Ambulance District personnel. With full knowledge of the possible consequences of my refusal of care, I hereby voluntarily refuse medical care and transportation by St. Charles County Ambulance District. Furthermore, I, for myself, my heirs, executors, administrators and assigns forever release and fully discharge St. Charles County Ambulance District, its officers, employees, medical consultants, hospitals, borrowed servants or agents from any and all liability or claims of whatever nature arising out of St. Charles County Ambulance District's effort to provide me with medical care and/or transportation and my consequent refusal, and I, therefore, agree to hold them completely and totally harmless and without fault unconditionally. ***I have read and fully understand all of the above.***

I also acknowledge that I have received a copy of the St. Charles County Ambulance District Notice of Privacy Practices. A copy of this form is as valid as the original.

☐ Medical Control Contact Talked to: _____

☐ Patient refused specific treatment (explain in narrative) _____

FIGURE 4-4 Refusal of care form. (Courtesy St. Charles County Ambulance District, St. Charles, Mo.)

4-4). The paramedic also should make it clear that the patient may call again for help despite the initial refusal. When possible, friends or family members should be encouraged to stay with the patient.

Cases in Which Care and Transport Are Not Needed

At times, care and transportation of a patient are not required, perhaps because of the patient's condition or because a request for help is canceled. After evaluating the patient or the scene, the paramedic may determine that circumstances do not warrant EMS transport (e.g., for a car crash without injuries or a patient who has left the scene). At this point, the paramedic should advise the dispatch center and document the event. If the EMS unit is canceled en route to the scene, the paramedic should make note of the canceling authority and the time of the cancellation. The canceling authority, for example, may be the dispatch center or the EMS supervisor. As with refusal of care, thorough documentation of these events can protect the paramedic from potential liability (see Chapter 6).

Interagency and Interfacility Transfers

Interagency transfers are those in which patient care duties are assigned (or "turned over") to another EMS unit. For example, a basic life support unit may intercept an ALS unit that is better able to manage the patient's needs; or, a fire rescue squad that provided initial emergency care but that does not have transport duties or capabilities may turn a patient in critical condition over to air ambulance personnel for speedier transport to a hospital. Documentation, tracking, and reporting systems should be established for these situations and followed consistently.

Interfacility (hospital to hospital) transfers occur between critical care hospitals and other facilities as approved by medical direction. They are arranged by the sending hospital to maximize the patient's safety and care. Some interfacility transfers are done for critical care patients, such as pediatric trauma patients, patients with severe burns, transplant candidates, cardiac patients, and patients with indwelling medical devices that support life (see Appendix, Advanced Practice Procedures for Critical Care Paramedics.) In some cases medical personnel from the sending hospital accompany the patient during the interfacility transfer. These personnel may include physicians, critical care nurses, respiratory therapists, or other specialty care professionals. Most sending hospitals have special interfacility transfer forms to document care en route; to provide for any standing orders; and to document the transfer of patient care at the new destination.

Some patients are transferred because of insurance requirements or to receive specialized care not available at the sending hospital. Paramedics should use a standard PCR or other form designated by their EMS agency to document these transfers.

NOTE

Interfacility transfers differ from the nonemergency transfer of a patient from a private physician's office, nursing home, convalescent care center, or other facility that may not be equipped to provide acute patient care needs.

Mass Casualty Events

A major incident may result in a large number of patients, and comprehensive documentation may have to be postponed until patients have been triaged and transported for definitive care (see Chapter 54). These are difficult and unusual situations; in these circumstances, the paramedic should follow local documentation procedures.

Exposure and Injury Reporting

EMS agencies have special forms for documenting and reporting a possible unprotected exposure to infectious disease organisms, hazardous chemicals, or a job-related injury. These reports are developed by the local EMS agency and their legal advisers. They must follow state and federal guidelines, as well as those established by the Occupational Safety and Health Administration (OSHA) and the Centers for Disease Control and Prevention (CDC), if applicable. (Reporting of a possible exposure to infectious disease organisms or hazardous chemicals is discussed in detail in Chapters 28 and 57).

Paramedics who have been injured on the job or who believe that they may have been exposed to an infectious disease organism should follow agency protocol and do the following:

1. Immediately contact the EMS supervisor or designated officer.
2. Seek medical care.
3. Thoroughly document the event.

DOCUMENT REVISION AND CORRECTION

As noted previously, a PCR sometimes must be revised or corrected. Most EMS agencies provide separate report forms for this purpose. If a separate report is needed, the paramedic should do the following:

- Make the revision or correction as soon as the need for it is realized.
- Note the purpose of the revision or correction and the reason the information did not appear on the original document.
- Note the date and time the revision or correction was made.
- Make sure the revision or correction was made by the original author of the document.

Acceptable methods of making revisions or adding information to a document vary by agency. Some include making the change to the original form; such changes must be initialed, and the date and time must be noted (this

method should not be used for electronic patient reports unless the program has a built-in mechanism to track the changes). Other methods include writing the corrections in the narrative; attaching a new report to the original; and providing supplemental narratives on a separate form, which is attached to the original. The paramedic should follow the policies set by the EMS agency and medical direction for revising or correcting reports.

CRITICAL THINKING

Consider this situation: Your supervisor asks you to change your documentation so that the insurance company will pay for the transport. What would you do?

BOX 4-4 Documentation Responsibilities of the Paramedic

The paramedic's professional responsibilities with regard to documentation include the following:

- View the task of documentation as one of utmost importance.
- Assume responsibility for self-assessment of all documentation.
- Appreciate the importance of good documentation to all health care personnel.
- Strive to set a good example in the completion of the documentation task.
- Respect the confidential nature of an EMS report.

CONSEQUENCES OF INAPPROPRIATE DOCUMENTATION

Incorrect or incomplete documentation can have serious consequences that have medical and legal implications. With an inaccurate, incomplete, or illegible PCR, caregivers may provide improper care to a patient. For example, a paramedic fails to mention that a patient with a possible myocardial infarction is allergic to ***amiodarone.*** The patient later becomes unconscious in the ED as a result of a ventricular rhythm disturbance. ***Amiodarone,*** an antidysrhythmic, might be administered, but in this case it could prove lethal for the patient. A thorough PCR completed in a professional manner may influence the decision of an attorney considering the merits of an impending lawsuit for negligence or malpractice. (The converse also is true if the documentation is not thorough and professional.)

Documentation should never become routine or superficial (Box 4-4). Good documentation should be completed in a timely manner and with careful attention to detail. This helps ensure that the PCR is medically and legally sound.

SUMMARY

- The patient care report is used to document the key elements of patient assessment, care, and transport.
- The four primary reasons for written documentation are that the medical community involved in the patient's care uses it; it is a legal record; it is important for reimbursement; and it is essential to data collection.
- The PCR should include dates and response times, difficulties encountered, observations at the scene, previous medical care provided, a chronological description of the call, and significant times.
- A properly written EMS document is accurate and complete, legible, timely, unaltered, and free of nonprofessional or extraneous information.
- Many approaches can be used to write the narrative. The paramedic should adopt only one approach and use it consistently to prevent omissions in report writing.
- Special documentation is necessary when a patient refuses care or transport; when care or transport is not needed; and for mass casualty events.
- Most EMS agencies have separate forms for revising or correcting the patient care report.
- Incorrect or incomplete documentation may have medical and legal implications.

CHAPTER

5 EMS Communications

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Outline the phases of the communications that occur during a typical emergency medical services (EMS) event.
2. Describe the role of communications in EMS.
3. Outline the basic model of communications.
4. Define common EMS communications terms.
5. Describe ways to communicate effectively using the primary modes of EMS communications.
6. Outline the elements of an EMS communications system.
7. Describe the characteristics of EMS communications operation modes.
8. Describe the role of dispatching as it applies to prehospital emergency medical care.
9. Outline techniques for relaying EMS communications clearly and effectively.
10. Describe the regulation of EMS communications.
11. Distinguish between EMS frequency ranges.
12. Outline procedures for EMS communications.

KEY TERMS

communications The process by which one individual or group transmits information to others.

decoding The process by which the intended meaning of information is interpreted.

duplex mode A communications mode in which traffic may be transmitted and received simultaneously through two different frequencies, one for transmitting and one for receiving.

EMS communications The delivery of patient and scene information (either in person, in writing, or through communications technology) to other members of the emergency response team.

encoding The process by which information is organized through a medium or channel.

Federal Communications Commission (FCC) A federal agency that has jurisdiction over interstate and international telephone and telegraph services and satellite communications.

multiplex mode A communications mode in which two or more different types of information can be transmitted simultaneously, in either or both directions, over the same frequency.

simplex mode A communications mode in which information can be transmitted or received in only one direction at a time. Simultaneous transmission cannot occur.

SOAP format A memory aid used to organize written and verbal patient reports; *SOAP* stands for *s*ubjective data, *o*bjective data, *a*ssessment data, and *p*lan of patient management.

team dynamics The unseen forces that operate in a team between different groups of people; will enable a group of people to act as one.

telemedicine Technological communications that allow the transmission of photographs, video, and other information directly from the scene to a hospital for physician evaluation and consultation.

EMS communications *refers to the delivery of information about the patient and the scene. The information may be delivered in person, in writing, or through various electronic devices to other members of the emergency response team. These members include telecommunicators, EMS personnel, emergency response workers, EMS system control and administration staff, and medical direction. This chapter addresses the complexities of communications that are vital aspects of the EMS system.*

PHASES OF COMMUNICATIONS DURING A TYPICAL EMS EVENT

A typical EMS event involves five phases of communications.[1] The first phase is the occurrence of the event. The second phase is the detection of the need for emergency services. The third phase is the notification and emergency response. The fourth phase is the EMS responders' arrival, treatment of the patient, and preparation for transport. (Treatment may require consultation with medical direction.) The fifth phase is preparation of the EMS crew for the next response.

In many urban areas, the public requests help by a phone call. This call goes to a communications center or *public safety answering point* (PSAP). Communications specialists receive the call. In the most modern systems, details about the origin of the call and any history of a response to that locale are displayed automatically on a console (Figure 5-1). The call taker uses digital technology to send these details to the telecommunicator, who sends a response unit to the scene. In some PSAP systems, the caller is given prearrival instructions by emergency medical dispatchers or other qualified personnel. The communication with the caller continues until the first EMS unit arrives at the scene.

DID YOU KNOW?

Vehicle Telemetry

Vehicle telemetry systems (e.g., OnStar, Tele-Aid, and others) are installed on some newer automobiles. They use a collection of sensors that send crash data to an adviser if the vehicle is involved in a moderate or severe front, rear, or side impact crash. Depending on the type of system, the data may include information on the severity of the crash, the direction of impact, airbag deployment, multiple impacts, and a rollover (if the system is equipped with appropriate sensors). Advisers can relay this information to emergency dispatchers, helping them quickly to determine the appropriate combination of emergency personnel, equipment, and medical facilities that may be needed. Telemetry systems also can pinpoint the location of the vehicle if it is equipped with a global positioning system (GPS). Since OnStar launched its program in 1996, the company has assisted its subscribers and others on the roadway in more than 100,000 crashes.[2]

NOTE

As described in Chapter 1, a *telecommunicator* is a person trained in public safety telecommunications. The term applies to call takers, dispatchers, radio operators, data terminal operators, or any combination of such functions in a public safety answering point located in a fire, police, or EMS communications center.

The EMS unit is dispatched to the scene. The paramedic crew advises the communications center of its response and arrival status by radio or electronically using a computer data terminal. The paramedics provide care at the scene of the emergency. They prepare ("package") the patient for transport and then deliver the individual to the receiving facility. After reporting has been done, the paramedics make the EMS vehicle ready for the next emergency call.

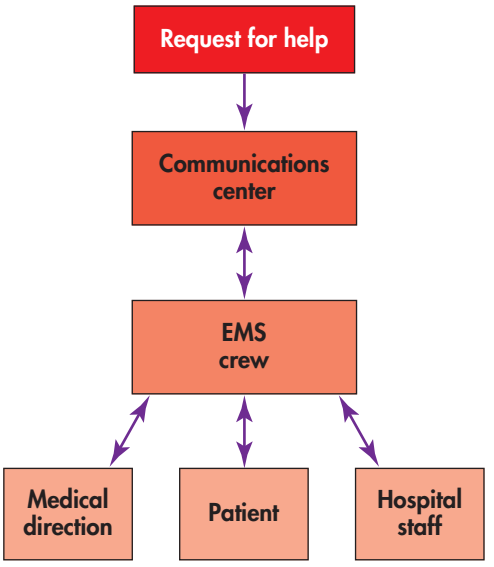

FIGURE 5-2 EMS communications.

ROLE OF COMMUNICATIONS IN EMERGENCY MEDICAL SERVICES

Verbal, written, and electronic communications allow the delivery of information between the person requesting help and the telecommunicator and between the telecommunicator and the paramedic. Communications occur between the paramedic, patient, hospital, and direct/online medical direction (if needed) and between the paramedic and hospital personnel who receive the patient on arrival at the emergency department (Figure 5-2). Good communication occurs only when key elements are in place. These elements make up the basic model of communications.

Basic Model of Communications

Communications can be verbal, nonverbal, or written in form. They serve a vital information function in the course of decision making. **Communications** is the process by which one individual or group transmits meaning to others. The basic model of communications describes the relationships between an idea, encoding, a sender, a medium or channel, a receiver, decoding, and feedback (Figure 5-3).

NOTE

The elements of successful communication described here apply to *all* types of communication between people. This includes communications with friends, family, coworkers, other emergency personnel, and other health care professionals. Successful communication is an important part of **team dynamics.**

The *idea* is the meaning that is intended in the communication. Conveying the idea requires two things. First, the sender must organize the intended meaning through a medium or channel; this is called **encoding.** (For example, the medium or channel may be written or verbal, facial or body expression, or voice modulation.) Second, the communication must be interpreted by the receiver; this is called **decoding.** The receiver provides feedback that indicates the idea was received. If the communication is fully successful, the idea intended by the sender will overlap with the feedback provided by the receiver. (That is, the receiver interprets, or decodes, the idea exactly as intended by the sender.) Four common barriers can prevent successful communication.[3]

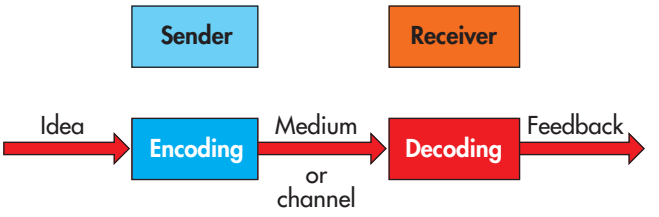

FIGURE 5-3 Basic model of communication.

1. *Attributes of the receiver*. Different people react in different ways to the same message or idea. A variety of personal reasons may affect the interpretation of the message. These reasons may include cultural differences, language barriers, or sensory deficits. For example, a patient from one culture may find personal touch comforting, whereas a patient from another culture may be offended by touching.
2. *Selective perception*. People tend to listen to only part of an idea or message. They block out other information. They do this for a variety of reasons (e.g., values, mood, motives of the sender). They may block out an idea when new information conflicts with established values, beliefs, or expectations. For example, a paramedic supervisor may not welcome or respect the input of a newly licensed paramedic.
3. *Semantic problems*. Commonly used words may have different meanings for different people. A common issue is the use of vague or abstract words or phrases. These words invite varying interpretation. Another problem is the use of medical terms and technical language (jargon); the receiver may not be able to understand these. For example, a paramedic may refer to a patient as "comatose" during a radio report to the hospital. The hospital staff member may ask for further clarification using the *a*lert, *v*erbal, *p*ainful, *u*nresponsive (AVPU) scale (see Chapter 19).
4. *Time pressures*. Time pressures can lead to distortions in communications. A major temptation when pressed for time is to bypass or "short circuit" normal channels. In these cases the immediate demands of the situation are met. However, a number of unintended consequences can result. For example, a paramedic may not document the medications administered at the scene to a patient in cardiac arrest. This can cause confusion about the next appropriate drug to be used.

CRITICAL THINKING
What tends to happen to you when you are talking with someone who continually interrupts you?

Paramedics should consider this basic model of communications and the common barriers that block good communications. These elements are the key to recall when a paramedic is conveying information to or receiving information from telecommunicators, coworkers, patients, bystanders, medical direction, and hospital personnel.

Proper Verbal Communications During an EMS Event

The role of proper verbal communications during an EMS event is to exchange system and patient information with other members of the response team. Communications must be done according to local protocol and patient privacy standards and regulations (see Chapters 4 and 6).

The terms used in EMS communications should be clear and conveyed in short narrative form. Technical or semantic jargon that cannot be understood clearly by all parties should be avoided. Some EMS systems use a code to shorten radio transmissions. However, the English language usually is preferred for written and verbal messages. Paramedics should keep in mind that many radio and phone communications are recorded. These recordings may be replayed for patient care audits, media broadcasts, and disciplinary hearings and also during legal proceedings. Professional conduct is important in all communications. In many communities, members of the public use scanners to monitor emergency services. Paramedics, therefore, must take steps to preserve a patient's confidentiality. They should not speak the patient's name or use descriptive phrases over unsecured airwaves.

Proper Written Communications during an EMS Event

As described in Chapter 4, written documentation during an EMS event serves several key purposes. It provides a written and legal record of the event. It conveys key clinical information from one part of the medical chain (EMS) to the next (the emergency department). In addition, documentation is an expected component of professional work. Written documentation of patient care activities becomes part of the patient's medical record. Other important ways in which written data can be used in the EMS system include the following:

- Medical audits
- Quality improvement/quality management
- Billing
- Data collection
- Research

NOTE
Verbal communications can be affected by the terms used. Likewise, the effectiveness of written documentation can be impeded by the use of technical terms. Semantic jargon also can hinder the message. These types of terms often cannot be understood clearly by all parties.

In addition to the patient care report (PCR), other types of documentation may be required by an EMS agency, such as:

- Personnel records documenting training and work assignments
- Call records that list or log dates, times, and other specifics of a call
- Vehicle maintenance records documenting vehicle service at regular intervals
- Vehicle and equipment cleaning records documenting procedures used to disinfect vehicle and emergency equipment
- Drug and equipment inventory records verifying daily checks of drug and fluid expiration, security measures for controlled substances as required by state and federal drug enforcement agencies; and monitor-defibrillator, radio, and telemetry checks
- Incident reports that document problem calls or unusual circumstances
- Records of significant exposures to communicable disease organisms or biological hazards
- Records of any possible hazardous substances to which the patient or paramedic may have been exposed

Technological Advances in the Collection and Exchange of Information

As technology evolves, it alters the way EMS gather and exchange information. Technology reduces the reliance on more traditional means of verbal and written communications. Examples of such advances include portable wireless voice and data devices, satellite terminals, global positioning systems (GPSs) for tracking emergency vehicles, diagnostic devices, laptop or handheld computers, and personal digital assistants (PDAs) (Figure 5-4). These and other devices can allow for real-time capture of EMS events and data. They can allow advanced notification and reduce the time to in-hospital diagnosis and therapy.

NOTE
Laptops and handheld computers can send patient information from a scene to a receiving hospital or a host computer. Then the data can be transferred electronically into a final report and patient record. This electronic information has the same legal status as a written document. The data take the place of the paper record of the incident.

FIGURE 5-4 Rugged computer used for EMS documentation.

COMMUNICATIONS SYSTEMS

The terms used to describe emergency communications technology are specific to the industry (Box 5-1). The following sections provide an overview of the simple and complex communications systems and their requirements as established by the **Federal Communications Commission (FCC).**[4]

Simple Systems

The minimum requirements for radio equipment used by an ambulance service include a self-contained desktop transceiver with a speaker, microphone, antenna, and mobile unit, as well as a two-way radio with multiple-frequency capability in the vehicle. Most EMS agencies also use handheld portable radios (often called simply *portables*). These radios are capable of communications contact with the base station and data recording. The portable radio protects the crew and aids optimum patient care by allowing continued contact with the communications center and medical direction. The data recording part of the device is on the dispatch or hospital radio or telephone. It offers medical and legal protection for the service and can verify transmissions when contact is disrupted.

Complex Systems

More advanced radio communications systems include remote consoles, high-power transmitters, repeaters, satellite receivers, and high-power multifrequency vehicle radios. Some services also use mobile transmitter steering, vehicular repeaters, mobile encode-decode capabilities, mobile data terminals, microwave links, and other sophisticated communications devices.

BASE STATIONS

Base stations usually are located on a high spot, such as a hill, mountain, or tall building. This location ensures optimum transmission and reception. Base stations generally are connected by telephone lines to dispatch centers, where all elements of the EMS response are coordinated. Depending on the locale, one dispatch center may be responsible for all fire, police, and EMS communications activities. Base station transmitters usually are equipped with an antenna to boost their signal.

MOBILE TRANSCEIVERS

Vehicle-mounted transmitters usually operate at lower outputs than base stations. They provide a range of 10 to 15 miles over average terrain. Transmission over flat land or water increases this range. However, transmission over mountainous terrain, dense foliage, or urban areas with tall buildings reduces the range. Transmitters with higher outputs are available. These transmitters may offer greater ranges for transmission. Multichannel units are preferred over single-channel radios because an EMS system uses many channels.

PORTABLE TRANSCEIVERS

Portable transceivers are hand-held or hand-carried devices. They are used when the paramedic is working away from the emergency vehicle. Portable transceivers usually have a limited range. Many systems boost the signal through a mobile or vehicular repeater. Portable transceivers may be single-channel or multichannel units.

REPEATERS

Repeaters act as a special type of long-range transceiver. They receive transmissions from a low-power portable or mobile radio on one frequency. At the same time, they retransmit it at a higher power on another frequency. Repeaters may be fixed or vehicle-mounted; EMS systems often use both. Repeaters are needed for large geographical areas. They are used to increase coverage between two or more portable or mobile units. Repeaters allow low-power units to receive other radio messages. They also allow two or more low-power units to communicate with each other when distances or obstructions normally would hinder such communications.

REMOTE CONSOLE

Most EMS systems use dispatch services located away from base stations. These remote centers control all base station functions. The remote center and base station are connected by dedicated telephone lines, microwave relay, or other radio means. Hospitals also often are equipped with a terminal that receives and displays telemetry transmissions. The remote console provides contact with paramedic crews in the field. Consoles for these systems include an amplifier, a speaker, a microphone, receiving capabilities, and remote control circuits.

SATELLITE RECEIVERS AND TERMINALS

Satellite receivers sometimes are used, depending on the area and the terrain. They are used to ensure that low-power units are always within coverage. The satellite receivers are strategically located and are connected to the base station or repeater by dedicated phone lines, radio, or microwave

BOX 5-1 Communications Terminology

9-1-1: A three-digit telephone number used to facilitate reporting of an emergency that requires a response by a public safety agency.

9-1-1 service area: The geographical area that has been granted authority by a state or local government body to provide 9-1-1 service.

abandoned call: A call placed to 9-1-1 in which the caller disconnects before the call can be answered by the public safety answering point (PSAP) telecommunicator.

advanced mobile phone service: The analog or digital radio interface used in wireless telephone systems.

alternate PSAP: A PSAP designated to receive calls when the primary PSAP is unable to do so.

alternate routing: A system for routing 9-1-1 calls to one or more designated alternate locations if all 9-1-1 trunks to a primary PSAP are busy or out of service. Alternate routing may be activated upon request or automatically, if detectable, when 9-1-1 equipment fails or the PSAP itself is disabled.

amplitude modulated: The encoding of a carrier wave by variation of its amplitude in accordance with an input signal.

attendant position: The customer premises equipment at which the telecommunicator answers and responds to calls.

automatic alarm and automatic alerting device: Any automated device that can access the 9-1-1 system for emergency services upon activation but that does not provide for two-way communication. Many states prohibit dialing of 9-1-1 by an automated device.

automatic call distributor: Equipment that automatically distributes incoming calls to available PSAP call takers in the order the calls are received or queues calls until a call taker becomes available.

automatic location identification: The automatic display at the PSAP of the caller's telephone number, the address or location of the telephone, and supplementary emergency services information.

automatic number identification (ANI): The telephone number associated with the access line from which a call originates.

backup PSAP: Typically, a disaster recovery answering point that serves as a backup to the primary PSAP and is not located in the same place as the primary PSAP.

basic 9-1-1: An emergency telephone system that automatically connects 9-1-1 callers to a designated answering point. Call routing is determined only by the originating central office. Basic 9-1-1 typically does not support ANI or automatic location identification.

call relay: Forwarding of pertinent information by a PSAP telecommunicator to the appropriate response agency; not to be confused with telephone relay service.

calling party hold: The capability of the PSAP to maintain control of a 9-1-1 caller's access line, even if the caller hangs up.

calling party's number: The callback number associated with a wireless telephone; similar to ANI for wireline telephones.

cell: The wireless telecommunications (cellular or PCS) antenna serving a specific geographical area.

circuit route: The physical path between two terminal locations.

computer-aided dispatch: A computer-based system that aids PSAP telecommunicators by automating selected dispatching and recordkeeping activities.

consolidated PSAP: An arrangement in which one or more public safety agencies choose to operate as a single 9-1-1 entity.

dedicated trunk: A telephone circuit used for a single purpose, such as transmission of 9-1-1 calls.

direct dispatch: The performance of 9-1-1 call answering and dispatching by personnel at the primary PSAP.

diverse routing: The practice of routing circuits along different physical paths to prevent total loss of 9-1-1 service in the event of a facility failure.

emergency call: A telephone request for public safety agency emergency services that requires immediate action to save a life, report a fire, or stop a crime; it may include other situations as determined locally.

emergency ring back: The capability of a PSAP telecommunicator to ring the telephone on a held circuit (a basic 9-1-1 feature); requires calling party hold; also known as *re-ring*.

emergency service trunks: Message trunks capable of providing ANI, connecting the serving central office of the 9-1-1 calling party and the designated enhanced 9-1-1 control office.

enhanced 9-1-1 (E9-1-1): An emergency telephone system that includes network switching, database, and customer premises equipment elements capable of providing selective routing, selective transfer, fixed transfer, ANI, and automatic location identification.

forced disconnect: The capability of a PSAP attendant to disconnect a 9-1-1 call even if the calling party remains off the hook; used to prevent overloading of 9-1-1 trunks.

global positioning system (GPS): A satellite-based technology for determining location.

highway call box: A telephone enclosed in a box and placed along a highway that allows a motorist to summon emergency and nonemergency assistance.

management information system: A program that collects, stores, and collates data into reports to allow interpretation and evaluation of information such as performance, trends, and traffic capacities.

master street address guide: A database of street names and house number ranges within their associated communities defining emergency service zones and their associated emergency service numbers to enable proper routing of 9-1-1 calls.

National Emergency Number Association: A not-for-profit corporation established in 1982 to further the goal of "One Nation—One Number." The association is a networking source that promotes research, planning, and training. It strives to educate, set standards, and provide certification programs, legislative representation, and technical assistance for implementing and managing 9-1-1 systems.

primary PSAP: A PSAP to which 9-1-1 calls are routed directly from the 9-1-1 control office.

public safety answering point (PSAP): A facility equipped and staffed to receive 9-1-1 calls. A primary PSAP receives the calls directly. If the call is relayed or transferred, the next receiving PSAP is designated a secondary PSAP.

selective routing: The routing of a 9-1-1 call to the proper PSAP based on the location of the caller. Selective routing is controlled by the emergency service number, which is derived from the customer's location.

telecommunicator: As used in 9-1-1, a person trained and employed in public safety telecommunications. The term applies to call takers, dispatchers, radio operators, data terminal operators, or any combination of such functions in a PSAP.

trunk: Typically, a communication path between central office switches or between the 9-1-1 control office and the PSAP.

Modified from National Emergency Number Association Technical Committee and PSAP Operational Standards Committee: *NENA master glossary of 911 terminology*, Arlington, Va, 1998, The Association.

relay. "Voting systems" automatically select the best audio signal. These systems pick up the signal from among multiple satellite receivers and the main base station receiver. (These also are used in other types of communications systems.)

Commonly available satellite terminals incorporate ground stations and transportable stations. They provide voice, data, and video communications. Portable satellite terminals are useful when other systems are not available. For example, they may be used during major disasters.

ENCODERS AND DECODERS

Selective call encoders look like a phone dial or the buttons of a push-button phone. When activated, the encoder transmits tone pulses or pairs of tones over the air. Receivers with decoders recognize the specific codes. This in turn opens the audio circuits of the receivers. Two-tone sequential paging alerts personnel using two pairs of specific frequency tones to address pagers and alert monitors selectively. A selective-address system usually has a code for calling all units within radio range *(all call)*.

Hospitals in certain regions of the United States are tied together by radio systems known as Hospital Emergency Administrative Radio (HEAR [by Motorola]) or Emergency Administrative Communications (EACOM by Ericson). Radios for these systems use 1500 Hz rotary pulse dialing to transmit specific groups of rotary tone pulses to designated hospital-based receivers. Most ambulance services have access to this system.

CELLULAR TELEPHONES

Many EMS systems use cellular phones (analog and digital). Cell phones are an alternative to dedicated EMS communications systems. One benefit of cell phones is that they have more channels. In addition, a cell phone offers a fairly secure link between EMS workers and area hospitals. A cell phone also allows the online physician to speak directly with the patient. However, the use of cell phones for emergency services also has some disadvantages. For example, network usage might limit channel access. Also, high network usage might create problems in maintaining continuous communications in some areas, which would be especially problematic in a community disaster. Other issues are lack of priority access and the fact that calls could not be monitored by other members of an emergency response team. For these reasons, many EMS agencies that use cell phones have a backup option. They often have backup radio communications capabilities (Box 5-2).

DID YOU KNOW

The U.S. Congress recently mandated conversion to *all digital television* (DTV) broadcasting, because digital frequencies are more efficient than analog frequencies. In addition, ending analog broadcasts will free up those frequencies for public safety communications and emergency response networks.

BOX 5-2 Cellular Phone Technology

An analog cell phone is actually a radio that allows two people to communicate on one frequency. The analog signal fluctuates with the rise and fall of the caller's voice. This produces a wildly oscillating electrical wave (a "copy" of speech). The signal can be heard at the receiver's end. Digital cell phones use the same radio technology but different frequencies. Moreover, they compress the caller's voice into digital 1s and 0s that remain stable for the length of their travel. At the receiver's end, the digital information is converted back to voice. A digital signal generally is thought to provide better sound quality. It also is thought to provide a more secure method of transmission than analog methods. In addition, digital technology provides the platform for wireless services such as data transmission and interactive computers.

DIGITAL MODES

Digital communication modes include digital phones, telemetry, facsimile ("fax") transmissions, and digital signals used in some wireless phone, paging, and alerting systems. Telemetric communications and facsimiles are transmitted using electronic signals, which are converted into audio tones. These tones are converted back into electronic signals by the receiver decoder. The signals then can be displayed or printed. Transmission of a patient's electrocardiogram is an example of telemetry.

COMPUTER TECHNOLOGIES

Computer technology (e.g., that used with automated external defibrillators [AEDs] and other devices) is capable of "saving" (preserving a record of) every step of data entry. Computers allow for (1) documentation in near real time; (2) sorting of information in many categories; (3) creation of multiple reporting formats; and (4) quick online and retrieval system data access. Computer terminals also are used by some communications centers to dispatch units automatically to a scene. As with most technologies, computer devices are subject to human error and machine limitations. Therefore, they require regular upgrades and user education.

NOTE

Advances in EMS communications technology and **telemedicine** continue to proceed at a rapid pace. Video cameras, fax machines, cellular networks, and the Internet now allow photographs, videos (including movie-type imaging), and other information to be sent directly from the scene to a hospital for physician evaluation and consultation.

Operation Modes Used for EMS Communications

The operation modes commonly used in EMS communications are the simplex, multiplex, duplex, and trunked modes.

SIMPLEX MODE

The **simplex mode** (Figure 5-5) requires a transmitter and receiver at each end of the communications path. Both elements operate on the same frequency. However, only one end may operate at a time. This mode allows speakers to send a message without interruption, although it slows the communications process and precludes the ability to discuss an emergency event.

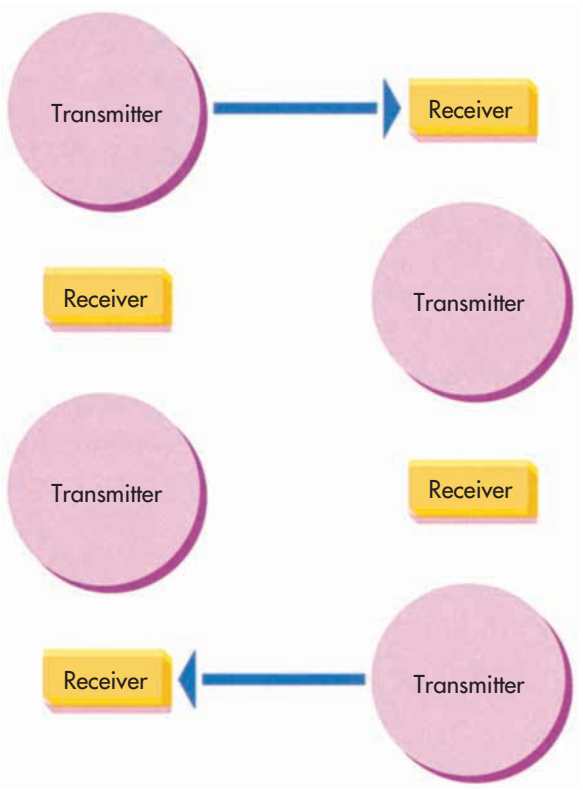

FIGURE 5-5 Simplex mode requires a transmitter and a receiver at each end of the communications path, both operating on the same frequency. In this mode, only one end may operate at a time.

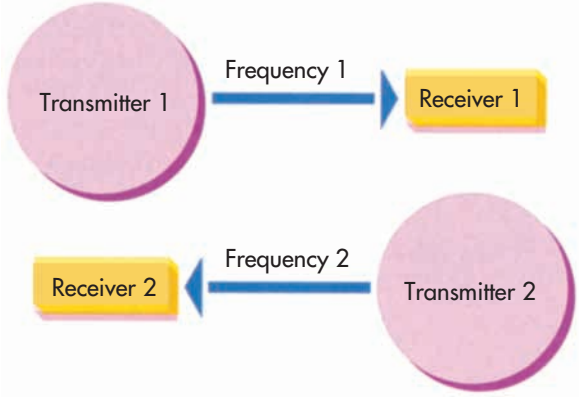

FIGURE 5-6 Duplex mode requires two frequencies so that both ends can communicate simultaneously.

DUPLEX MODE

The **duplex mode** (Figure 5-6) uses two frequencies that allow both parties to communicate at the same time. The advantage of this mode is that either party can interrupt the other to facilitate discussion. However, a tendency exists for each end to interrupt the other.

MULTIPLEX MODE

The **multiplex mode** (Figure 5-7) has the advantage of transmitting telemetry and voice simultaneously from a field unit. With this mode either party can interrupt as needed, which facilitates discussion. As with the duplex mode, each party tends to interrupt the other. In addition, voice transmission may interfere with the transmission of data. Multiplex is the most common mode currently used by most EMS systems.

TRUNKED SYSTEM

Trunking refers to systems that have five or more repeaters that work as a group. Each repeater is on a different channel. The trunking system may belong to a single user (e.g., a specific EMS agency or police department), or it may be shared by a number of public service agencies. When radio transmissions originate, computerized scanning automatically finds an available repeater in the system. The computer then switches the transmission to the chosen repeater. As one fleet captures an open channel, it locks out all other users who share the system. This bars interference from other agencies. The trunked system is advantageous in major metropolitan operations in which radio frequencies are used heavily.

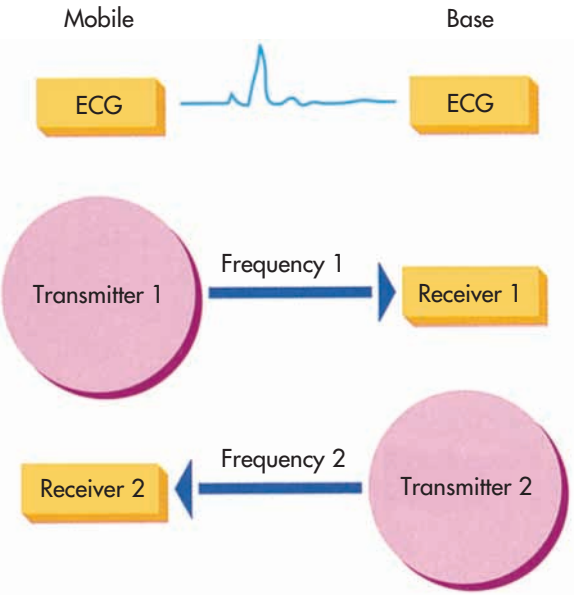

FIGURE 5-7 Multiplex mode operates similarly to duplex mode but has added capabilities, such as simultaneous electrocardiogram and voice transmission.

COMPONENTS AND FUNCTIONS OF DISPATCH COMMUNICATIONS SYSTEMS

The dispatch communications system is the public safety answering point (Box 5-3). The following are some of the functions of an effective EMS dispatch communications system.[5]

- *Receive and process calls for EMS assistance:* Calls for EMS assistance are received and recorded by the dispatcher, who selects an appropriate course of action for each call. This function involves obtaining as much information as possible about the emergency event, including the caller's name, callback number, and address; it also may involve dealing with distraught callers. In addition, emergency care instructions may be provided while the EMS crew is dispatched.
- *Dispatch and coordinate EMS resources:* The dispatcher directs the proper emergency vehicles to the correct address. In addition, the dispatcher coordinates the movements of emergency vehicles while en route to the scene, to the medical facility, and back to the operations base.
- *Relay medical information:* The dispatcher may provide a telecommunications channel between appropriate medical facilities and EMS personnel; firefighters, the police, and rescue workers; and private citizens. The channel may consist of telephone, radio, or biomedical telemetry.
- *Coordinate with public safety agencies:* The dispatcher provides for communications between public safety units (fire department, law enforcement, rescue workers) and elements of the EMS system. This facilitates the coordination of services such as traffic control, escort, fire suppression, and extrication. The dispatcher ensures an integrated, well-coordinated system. To do so, the dispatcher must know the location and status of all EMS vehicles. The dispatcher also must know the availability of support services (e.g., utility companies, coroner). In larger systems, computer-aided dispatching may be used. This advanced technology allows one or more of the following capabilities or functions:
  - Automatic emergency medical dispatch
  - Automatic entry of 9-1-1
  - Automatic call notification/request for assistance
  - Automatic interface to automatic vehicle location (AVL) with or without map display (Figure 5-8)
  - Automatic interface to mobile data terminal
  - Computer messaging among multiple radio operators, call takers, or both
  - Dispatch note taking, reminder aid, or both
  - Emergency medical dispatch review
  - Manual or automatic updates of unit status
  - Manual entry of call information
  - Radio control and display of channel status
  - Standard operating procedure review
  - Telephone control and display of circuit status

BOX 5-3 9-1-1, Enhanced 9-1-1, and Computer-aided Dispatch Systems

In 1988 the number 9-1-1 was designated as the universal emergency telephone number (see Chapter 1). The number was chosen by the American Telephone and Telegraph Company. The number offers the public a toll-free number for reaching a public safety answering point. (This service is still not available in all areas.) Since 1988, enhanced 9-1-1 has been created. This system, which is used in many areas of the country, allows for automatic caller location and identification. It also shows the caller's number and address on a terminal at the communications center.

The most advanced centers use a computer-aided dispatch system that monitors the available resources. The system makes an assignment based on access and routes for the ambulance closest to the map grid shown on the terminal. Global positioning systems tell the telecommunicator or system status controller which unit is closest to the origin of the call by air miles or by road miles if an intelligent map (also known as a "smart map") is used automatically to route the unit closest to the scene. That unit then is sent to the scene. The telecommunicator monitors the call from beginning to end and records status changes using digital media (e.g., tapes, CDs, or DVDs).

SHOW ME THE EVIDENCE

EMS calls from 2 years in an emergency medical dispatch (EMD) system in a California suburb that totaled 500 or more in one dispatch category were compared to the prehospital patient care report for those same calls. The researchers wanted to see whether the dispatch code predicted prehospital use of medications and other interventions. They found that the EMD system had "only a modest ability" to predict which patients would need advanced life support (ALS) interventions. More medicines were given to patients with shortness of breath, chest pain, diabetic problems, and altered mental status.

From Sporer KA et al: Can emergency medical dispatch codes predict prehospital interventions for common 9-1-1 call types? *Prehosp Emerg Care* 12:470-478, 2008.

FIGURE 5-8 AVL mapping system in an ambulance cab.

DID YOU KNOW?

Enhanced 9-1-1

The rules established by the Federal Communications Commission (FCC) for wireless enhanced 9-1-1 (E9-1-1) are intended to improve the effectiveness and reliability of wireless 9-1-1 services by providing 9-1-1 dispatchers with additional information on wireless 9-1-1 calls. The wireless E9-1-1 rules apply to all wireless licensees, broadband Personal Communications Services (PCS) licensees, and certain Specialized Mobile Radio (SMR) licensees.

The FCC has divided its wireless E9-1-1 program into two parts, phase I and phase II. Under phase I, within 6 months of a valid request by a local public safety answering point (PSAP), wireless carriers must provide the PSAP with the telephone number of the originator of a wireless 9-1-1 call and the location of the cell site or base station transmitting the call.

Under phase II, within 6 months of a valid request by a PSAP, wireless carriers must begin providing more precise information to PSAPs, specifically, the caller's latitude and longitude. This information must meet FCC accuracy standards, generally to within 50 to 300 m, depending on the type of technology used. The deployment of E9-1-1 requires the development of new technologies and upgrades to local 9-1-1 PSAPs, in addition to coordination among public safety agencies, wireless carriers, technology vendors, equipment manufacturers, and local wireline carriers.

From Public Safety and Homeland Security Bureau: *Enhanced 9-1-1: wireless services.* http://www.fcc.gov/pshs/services/911-services/enhanced911/Welcome.html. Accessed August 3, 2010.

Dispatcher Training

Many EMS and public safety agencies require specialized medical training for their dispatch personnel. This training may include the Association of Public Communications Officials and Emergency Medical Dispatch Program (which is based on the National Standard Curriculum for Emergency Medical Dispatch, established by the National Highway Traffic Safety Administration). Emergency medical dispatchers are trained to do the following[6]:

- Use locally approved emergency medical dispatch guide cards (customized to local protocols and EMS response priorities)
- Quickly and properly determine the nature of the call
- Determine the priority of the call
- Dispatch the appropriate response
- Provide the caller with instructions to help treat the patient until the responding EMS unit arrives

A background of training in EMS helps the telecommunicator understand functions of the EMS system, personnel capabilities, and equipment limitations. The training also arms the dispatcher with the protocols for giving prearrival instructions, such as performing cardiopulmonary resuscitation (CPR) or administering ***aspirin*** to a patient with a coronary event. These protocols may mitigate the event before the EMS unit arrives.

A variety of dispatching systems and procedures are in place across the United States. Some are the simple call received–ambulance dispatched types; others are the more advanced call prioritization–prearrival instructions systems.

SHOW ME THE EVIDENCE

A prospective, experimental, before-and-after trial was conducted in a small Connecticut city with a population of 125,000 in which a first responder fire department engine company was routinely dispatched on most EMS calls. The purpose of the study was to see whether changing the emergency medical dispatch (EMD) protocol would reduce the call volume of first responder engine companies without affecting patient safety. Before the protocol was implemented, engine companies responded to 84.3% of calls. In the after phase, they were dispatched to 39.1% of EMS calls. The researchers estimated that only 0.55% of patients were undertriaged. They cautioned that these results may not be applicable to all EMS systems because of the diversity of response modes and dispatch protocols. They concluded that in their system, EMD protocols can safely limit the number of first responder runs.

From Cone D et al: Can emergency medical dispatch systems safely reduce first-responder call volume? *Prehosp Emerg Care* 12:479-485, 2008.

Call Prioritization—Prearrival Instructions Systems

In a call screening–prearrival instructions system, an emergency medical dispatcher, paramedic, or nurse determines the type of assistance needed for an emergency call. This may involve referring the caller to other services, choosing a basic life support (BLS) or an advanced life support (ALS) response, selecting a private or public EMS agency, and determining the appropriate use of audible and visual warning devices.

While dispatching the proper unit, the dispatcher can give the caller prearrival instructions. These instructions are crucial for several reasons:

- They provide the caller with instant help.
- They complement the call prioritization process.
- They allow the dispatcher to give updated information to responding units.
- They may be lifesaving in critical incidents.
- They provide emotional support for the caller, bystander, or victim.

CRITICAL THINKING

What are some possible consequences of a dispatching error?

REGULATION

As stated previously, radio communications in the United States are regulated by the FCC. This commission develops rules and regulations for the use of all radio equipment and

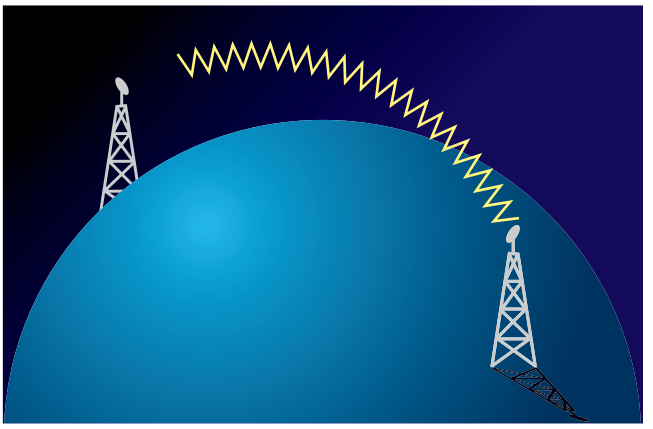

FIGURE 5-9 VHF low band.

frequencies. In addition to the FCC, state and local governments may have rules and regulations for radio operations. Paramedics must be knowledgeable about these agencies and must follow their guidelines. The primary functions of the FCC include the following:

- Licensing and frequency allocation
- Establishing technical standards for radio equipment
- Establishing and enforcing rules and regulations for equipment operation, including monitoring frequencies for appropriate usage and spot-checking for appropriate licenses and records

CRITICAL THINKING
Why are these rules and regulations needed for good EMS communications?

EMS Frequency Ranges

For public safety radio, very high frequency (VHF) may be defined as VHF low band (32 to 50 megahertz [MHz]) and VHF high band (150 to 174 MHz). A number of VHF low-band and VHF high-band frequencies are assigned strictly to two-way use or one-way paging. These frequencies normally operate in a simplex mode. UHF frequencies are used in either half-duplex, duplex, or multiplex modes.

VHF low-band signals (Figure 5-9) generally have the greatest range. They usually cover a greater distance than VHF high band or ultra high frequency (UHF) band. However, these low-band signals follow the curvature of the earth's surface; therefore, they are subject to noise interference and physical or structural interference. Consequently, although these signals have the best range, they may not provide the best coverage.

VHF high-band (Figure 5-10) signals generally have medium range. They travel in straight lines rather than following the earth's curvature. This virtual "straight line" characteristic means that high-band signals more easily reflect around buildings and other structures. These signals may provide better radio coverage in some areas.

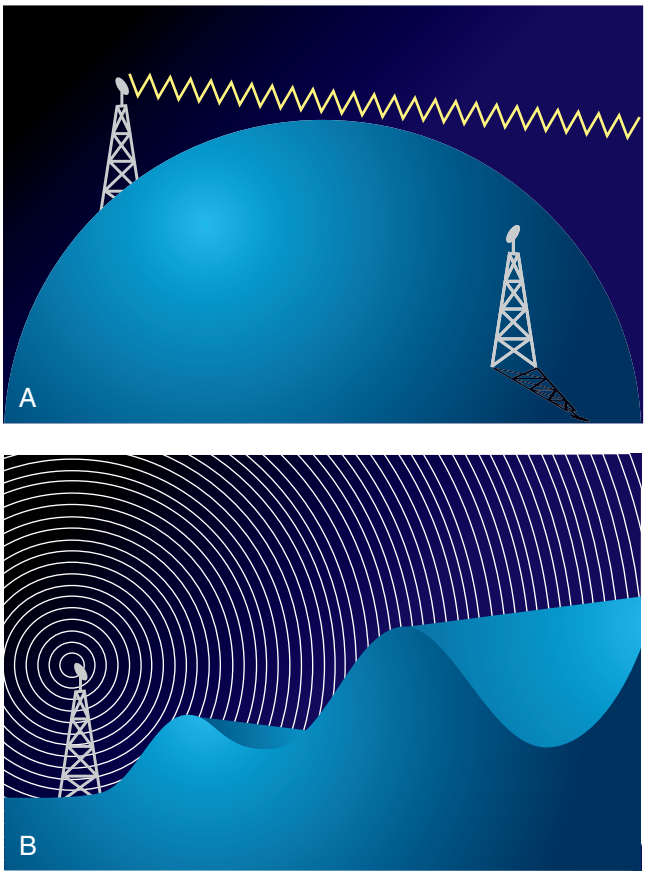

FIGURE 5-10 VHF high band.

In 1974 the FCC established a system of radio frequencies called *Special Emergency Radio Services* (SERS). These frequencies were to be used by EMS systems, hospitals, school buses, and rescue operations. Of the approximately 75 radio channels in this group, 10 UHF channels were designated for medical communications: eight for paramedic to hospital communications and two for dispatching (Table 5-1). EMS-only communications were confined to the 450 to 470 MHz UHF frequency band and five VHF frequencies.

UHF-band signals (Figure 5-11) generally have a limited range. They are more "straight line sensitive" than VHF high-band signals. However, the UHF band's ability to reflect or bounce around buildings exceeds that of the VHF high band. In metropolitan areas, UHF band may be the most effective frequency. Of the three bands, UHF is the least susceptible to noise interference. UHF also can reach into and out of structures more easily.

Public Safety 800 MHz Frequencies

Over the years, the growth of EMS systems and other public service operations has resulted in overcrowded frequencies and radio congestion. In 1987 the FCC allocated an additional band (821 to 824 MHz and 866 to 869 MHz) to SERS assignments. This helped resolve some of the communications problems. The 800 MHz signals generally

TABLE 5-1 UHF Channels Designated for Medical Communication

	Base Transmit	Base Receive	Recommended Use
Med 1	463.000	468.000	EMS to medical direction
Med 2	463.025	468.025	EMS to medical direction
Med 3	463.050	468.050	EMS to medical direction
Med 4	463.075	468.075	EMS to medical direction
Med 5	463.100	468.100	EMS to medical direction
Med 6	463.125	468.125	EMS to medical direction
Med 7	463.150	468.150	EMS to medical direction
Med 8	463.175	468.175	EMS to medical direction
Med 9	462.950	467.950	Dispatch
Med 10	462.975	467.975	Dispatch

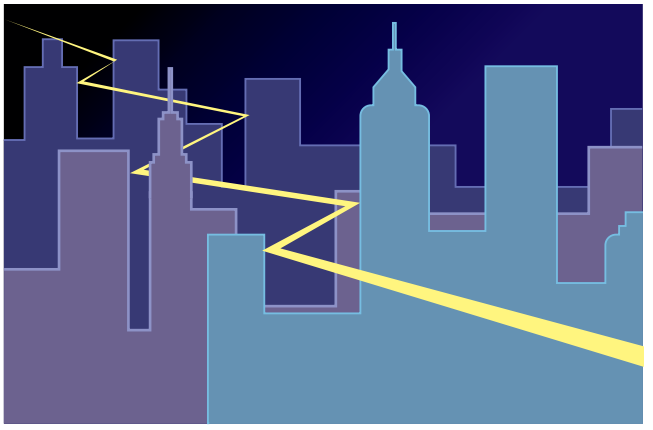

FIGURE 5-11 UHF band.

have a limited range, because they are more straight line than VHF high-band signals. With the use of repeaters, however, the 800 MHz band is able to reflect or bounce around buildings better than are the VHF high band and the UHF 400 MHz band. As such, the 800 MHz spectrum is best suited for use in urban areas.

To ensure the efficiency of the 800 MHz band, the FCC established "trunking" requirements. In the systems required, five or more repeaters (each on a different channel) work together as a group. The trunking system may belong to a single user, such as a specific EMS agency or police department. The system also may be shared by a number of public service agencies. As explained previously, when a radio transmission is originated, computerized scanning automatically finds an available repeater in the system. It then switches all radios in the fleet to the selected repeater. As one fleet captures an open channel, it locks out all other users who share the system. This prevents interference from other agencies. Several groups have helped the FCC reorganize the management of frequencies for public service operations, with the goal of improving the ability of public service agencies to communicate with each other.

NOTE

Cellular phone companies also use the 800 MHz band. This can cause congestion and can interfere with public service communications, especially during a large-scale incident or major disaster. This type of communications gridlock occurred during the 9/11 attacks on the World Trade Center in New York in 2001. Work is underway to "reband" the 800 MHz system. This will increase the space of the frequencies to accommodate the communications needs of commercial carriers and public service agencies.

In 1995 the FCC, along with the National Telecommunications and Information Administration (NTIA), established the Public Safety Wireless Advisory Committee (PSWAC) with the goal of addressing the communications needs of public service agencies through the year 2010. One of their recommendations has been the formation of a national broadband license for public safety.[7] The FCC remains committed to a policy goal of a nationwide 700 MHz broadband network for public safety. It currently is acquiring a number of frequencies in the 700 MHz band that had been used by television channels before the switch to all-digital TV in 2009.

PROCEDURES FOR EMS COMMUNICATIONS

Most EMS systems use a standard radio communications protocol. This protocol includes the desired format for message transmission and key words and phrases. This format aids professional and efficient radio communication within the system. General guidelines for radio communications include the following:

- Think before you speak (formulate the message) to ensure that the communication will be effective.
- Speak at close range (2 to 3 inches) when talking into a microphone.
- Speak slowly and clearly. Enunciate each word distinctly and avoid words that are difficult to hear.

- Speak in a normal pitch without emotion.
- Be brief and concise. Break up long messages into shorter ones.
- Avoid codes unless they are systems-approved. Avoid dialect or slang.
- Advise the receiving party when the transmission has been completed.
- Confirm that the receiving party has received the message.
- Always be professional, polite, and calm.

CRITICAL THINKING

Can you think of three reasons a concise EMS radio report is essential?

DID YOU KNOW?

NATO Alphabet Chart

The NATO alphabet assigns code words to the letters of the English alphabet acrophonically (e.g., *alfa* for A, *bravo* for B, and so on). This system ensures uniform pronunciation of critical combinations of letters and numbers, making them more easily understood by those who transmit and receive voice messages. It also ensures the intelligibility of voice signals over radio links.

A–Alfa	**B**–Bravo	**C**–Charlie	**D**–Delta	**E**–Echo	**F**–Foxtrot
G–Golf	**H**–Hotel	**I**–India	**J**–Juliet	**K**–Kilo	**L**–Lima (*Lee-ma*)
M–Mike	**N**–November	**O**–Oscar	**P**–Papa	**Q**–Quebec	**R**–Romeo
S–Sierra	**T**–Tango	**U**–Uniform	**V**–Victor	**W**–Whiskey	**X**–Xray
Y–Yankee	**Z**–Zulu				

From North Atlantic Treaty Organization: *NATO phonetic alphabet chart*. http://74.125.95.132/search?q=cache:BFkrJ90WLsUJ:www.lindagranfield.com/NATO_alphabet.doc+%22nato%22+Alphabet+chart%22&hl=en&ct=clnk&cd=1&gl=us&lr=lang_en. Accessed August 3, 2010.

Relaying Patient Information

A standard format of transmission may be developed as a protocol for some EMS agencies. This format allows the best use of communications systems: (1) it limits radio air time; (2) physicians can receive details quickly about the patient's condition; and (3) the chance that any critical details will be omitted is reduced (Box 5-4). (Patient assessment findings are presented in Part Five.)

Patient information can be reported to the hospital or dispatcher by radio or phone. Although the order of information delivery may vary by EMS system and scenario, the radio report should be brief and concise and should contain the following:

- Unit and personnel identification
- Description of the scene or incident
- Patient's age, gender, and approximate weight (if drug orders are needed)
- Patient's chief complaint
- Associated symptoms
- Brief pertinent history of the present illness or injury
- Pertinent medical history, medications, and allergies
- Pertinent physical examination findings, such as:
  - Level of consciousness
  - Vital signs
  - Neurological examination
  - General appearance and degree of distress
  - Electrocardiogram results (if applicable)
  - Diagnostic findings (e.g., serum glucose)
  - Trauma index or Glasgow Coma Scale (if applicable)
  - Other pertinent observations and significant findings
- Any treatment given
- Estimated time of arrival

BOX 5-4 Sample Radio Report

"This is paramedic Sanders with Medic One. We are en route to your facility with a 6 minute ETA. We have a 17-year-old female with a possible head injury. We were called to the scene for a patient who had fallen from her skateboard and struck her head. On arrival, the patient appeared drowsy and confused. Bystanders described the patient as having a seizure lasting less than 1 minute after her fall. The patient has a large hematoma on the left temporal area of her head. No other signs of trauma are noted. Pupils are equal and react to light. No medical history is available. We have the patient on 15 liters of oxygen by nonrebreather. She is immobilized with a C-collar and long spine board. I have established a 16-gauge IV in her left forearm with normal saline, TKO. She is still drowsy but rouses to voice at this time. BP 118/64, respirations are 16 and regular, pulse is 88 with normal sinus rhythm. SpO_2 is 99%; skin is pink, warm and dry. Lung sounds are clear. Blood sugar is 136 mg/dL. No orders requested at this time."

- Request for orders from or further questions for the medical direction physician

NOTE

The use of telemetry to transmit a patient's electrocardiogram usually is reserved for patients who require diagnosis of a 12-lead electrocardiogram (see Chapter 22). Telemetry transmission uses excessive air time. If such a transmission is warranted, 15 to 30 seconds of electrocardiogram transmission usually is adequate.

SOAP Format

Many paramedics use the **SOAP format** (see Chapter 4) or a similar method to organize their written and verbal patient reports. To review, *SOAP* is an acronym for the following:

- *S*ubjective data: All patient symptoms, including the chief complaint, associated symptoms, history, current medications and allergies, and information provided by bystanders and family members.
- *O*bjective data: Pertinent physical examination information, including vital signs, level of consciousness, physical examination findings, electrocardiogram results, pulse oximetry readings, and blood glucose determinations.
- *A*ssessment data: The paramedic's clinical impression of the patient based on subjective and objective data.
- *P*lan of patient management: Treatment that has been provided and any requests for additional treatment.

General Procedures for the Exchange of Information

When communicating with medical direction, the paramedic should repeat all orders received from the physician. Any order that is unclear should be confirmed. The paramedic should also repeat all drug orders for confirmation. The receiving hospital should be informed of any significant changes in the patient's status before and during transport. General procedures for the exchange of information include the following:

- Protect the patient's privacy.
- Use proper unit numbers, hospital numbers, names, and titles.
- Avoid slang and profanity.
- Use the echo procedure (repeat what was heard) when receiving directions from the dispatcher or physician.
- Obtain confirmation that the message was received.

When performing the hand-off of patient care to the receiving facility (see Chapter 6), the paramedic should make the final verbal report to the person who will be assuming responsibility for the patient. This report may be only a short update if the person receiving the patient has been following the care given in the field and en route to the emergency department. If this person is not familiar with the patient, the report should be complete. In either case, all pertinent information about the patient should be conveyed during the hand-off.

SUMMARY

- EMS communications refer to the delivery of information. The patient and scene information is delivered to other key members of the emergency response team.
- Typical EMS events have five phases: (1) the occurrence of the event; (2) detection of the need for emergency services; (3) notification and emergency response; (4) EMS arrival, treatment of the patient, and preparation of the patient for transport; and (5) EMS preparation for the next response.
- Communications is the process by which one person or group transmits meaning to others. The sender encodes a message that the receiver decodes. Four barriers to communication include the attributes of the receiver; selective perception; semantic problems; and time pressures.
- Proper verbal and written communications allows the delivery of information between the members of the emergency team, the patient, and the community. Communications should be brief, clear, and confidential.
- EMS communications involve both simple and complex systems. A simple system includes a desktop transceiver and two-way radio. Complex systems include high-power communications capabilities.
- Operation modes used in EMS communications include the *simplex mode*, which permits only one person to talk at a time; the *duplex mode*, which allows two people to converse at the same time; the *multiplex mode*, which can transmit telemetry and voice simultaneously; and *trunked systems*, which use five or more repeaters to provide communications channels in busy systems.
- The functions of an effective dispatch communications system include receiving and processing calls for EMS assistance, dispatching and coordinating EMS resources, relaying medical information, and coordinating with public safety agencies. Some emergency dispatchers provide prearrival instructions for patient care.
- In the United States, the FCC regulates communications over the radio. Paramedics must be familiar with and follow the rules and guidelines of the FCC and those of state and local regulatory agencies.
- EMS frequency ranges include VHF bands, UHF bands, and 800 MHz.
- Establishing a standard format for transmission of patient information is important. It allows the best use of communications systems: it reduces the use of radio air time; allows physicians to receive details about the patient quickly; and reduces the chance that any critical details will be omitted.

CHAPTER

6 Medical and Legal Issues

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the basic structure of the legal system in the United States.
2. Explain how laws affect the paramedic's practice.
3. List situations the paramedic is legally required to report in most states.
4. Describe the four elements of a claim of negligence.
5. Describe measures paramedics may take to protect themselves from claims of negligence.
6. Describe the paramedic's responsibilities regarding patient confidentiality.
7. Outline the process for obtaining expressed, informed, and implied consent.
8. Describe legal complications relating to consent.
9. Describe actions to be taken in a refusal of care situation.
10. Describe legal considerations in situations that require the use of force.
11. Describe legal considerations related to patient transportation.
12. Outline legal implications related to resuscitation and death of a patient.
13. List the paramedic's responsibilities at a crime scene.

KEY TERMS

abandonment The act of terminating medical care without legal excuse or of turning care over to personnel who do not have the training and expertise appropriate for the patient's medical needs.

administrative law Regulations developed by a government agency to provide details about the function and process of the law.

advance directive A legal document in which an individual specifies what should be done for his or her health if the person is unable to make medical decisions because of injury, illness, or lack of decisional capacity.

assault Creating apprehension; also, unauthorized handling and treatment of a patient.

battery Physical contact with a person without consent and without legal justification.

borrowed servants A legal doctrine that refers to a servant who serves two "masters" (e.g., an Emergency Medical Technician [EMT] who is employed by a municipality but who is supervised by a paramedic).

breach of duty A breach of a professional duty to act.

civil law An area of law that deals with "private" complaints brought by one person (the plaintiff) against another person (the defendant); also known as *tort law*.

common law Law that comes from societal acceptance of customs or norms of behavior over time; also known as *case law* or *judge-made law*.

compensable damages Damages awarded in a lawsuit that may include medical expenses, lost earnings, conscious pain and suffering, and wrongful death.

criminal law A type of law in which the federal, state, or local government prosecutes individuals for violating a law.

decisional capacity Patients' ability to make their own health care decisions.

defamation Saying something untrue about a person's character or reputation without legal privilege or the person's consent.

dependent practice A medical provider who provides a certain type of care that falls under the same scope of practice as a physician but that requires medical oversight.

depositions Testimonies taken under oath in places other than a courtroom.

discovery The judicial process in which documents are exchanged and depositions and interrogatives are taken.

duty to act The duty of a party to take necessary action to prevent harm to another party; this duty may be formal or contractual.

emancipation The state of being legally released from parental control and supervision.

expressed consent Verbal or written consent to treatment.

false imprisonment Intentional and unjustifiable detention of a person.

Good Samaritan laws State laws that are passed to encourage people to help others in an emergency without fear of litigation.

implied consent The presumption that an unconscious or incompetent person would consent to lifesaving care.

informed consent Consent obtained from a patient after all facts necessary for the person to make a reasonable decision have been explained.

interrogative A set of questions about a lawsuit that is answered in consultation with the party's lawyer.

invasion of privacy The release, without legal cause, of details about a patient's private life that might expose the person to ridicule, notoriety, or embarrassment.

involuntary consent Treatment granted by authority of law.

legislative law Laws made by legislative branches of government.

libel Making false statements about a person with malicious intent or reckless disregard for the falsity of the statements; includes statements made in writing or through the mass media.

malfeasance Performing a wrongful or unlawful act.

malpractice insurance Liability insurance carried by health care professionals.

mandatory reporting The requirement by law that health care professionals report certain types of cases, such as abuse and neglect.

medical malpractice Professional negligence by act or omission by health care personnel in which the care provided deviates from accepted standards of practice in the medical community and causes injury to the patient.

medical practice act A law that governs the practice of medicine.

misfeasance Performing a legal act in a manner that is harmful or injurious.

negligence Failure to use such care as reasonably prudent EMS personnel would use in similar circumstances.

nonfeasance Failure to perform a required act or duty.

protected health information (PHI) Any information about health status, provision of health care, or payment for health care that can be linked to a specific individual.

proximate cause Proof that a negligent act or lack of action caused an injury or worsened an existing injury.

punitive damages Damages awarded in a lawsuit that may be in excess of compensable damages; damages meant to punish the person at fault and to deter others from causing such harm in the future.

regulations Legal restrictions promulgated by a government authority.

scope of practice With regard to EMS personnel, the range of duties and skills paramedics are allowed and expected to perform when necessary.

settlement An agreement to accept an amount of money in exchange for a promise not to pursue a legal claim.

slander Making false verbal statements about a person.

standard of care A measure of competence of a professional.

statutes Formal written enactments of a legislative authority that governs a state, city, or county.

transcript A formal record of questions and answers that may be used during a trial.

vicarious liability A form of liability in which one person is liable for the negligent actions of another person, even though the first person was not directly responsible for the injury.

Historically, only hospitals and physicians were affected by **medical malpractice.** *This is because EMS personnel were not expected to meet professional standards of patient care. However, with state and national certification, licensure, and the paramedic's role as a health care professional, medical liability for EMS personnel and their employers has become a real concern.*

(Courtesy Ronald Olschwanger.)

LEGAL DUTIES AND ETHICAL RESPONSIBILITIES

The paramedic's legal duties are to the patient, the employer, the medical director, and the public. These duties are defined by **statutes** and **regulations** that are based on commonly accepted standards of medical care. As do other health care professionals, paramedics have ethical responsibilities in addition to legal duties. These ethical responsibilities include the following:

- Responding with respect to the physical and emotional needs of every patient
- Maintaining mastery of skills
- Participating in continuing education and refresher training
- Critically reviewing one's own performance and taking steps to improve it
- Reporting honestly
- Respecting confidentiality
- Working cooperatively and with respect with other emergency personnel and health care professionals
- Staying current on new concepts and modalities

Failure to perform EMS duties properly can result in civil or criminal liability. As described in this chapter, the best legal protection is providing appropriate assessment and care to the patient. This care should be coupled with correct and full written documentation.

NOTE
Laws pertaining to patient care delivery vary by state. Every paramedic should be aware of the medical practice act in his or her state and other regulatory statutes that pertain to EMS. If necessary, the paramedic should consult with a private attorney experienced in EMS law or the state attorney general's office (or its equivalent) to clarify state laws and their application to EMS activities. The information in this chapter is *general* information and is not intended to be a complete guide to the legislative system, EMS laws, or regulations of any state.

THE LEGAL SYSTEM

The structure of the legal system in the United States is composed of five types of law: legislative law, administrative law, common law, criminal law, and civil law.[1]

- **Legislative law** is made by legislative branches of government. Examples of these branches are city councils, district boards, general assemblies, and Congress. The power of these bodies to make law is defined by statutes, state constitutions and, in the case of Congress, the U.S. Constitution.
- **Administrative law** refers to regulations developed by a government agency to provide details about the function and process of the law. An example is the general requirement for paramedic licensure. These regulations may address areas such as examinations, licenses, and maintenance of records. Regulatory agencies may hold disciplinary hearings on the revocation or suspension of licenses. An example of a regulatory agency is a state EMS bureau.
- **Common law** is also known as case law or judge-made law. This law is derived from societal acceptance of customs or norms of behavior over time. It is based on the decisions of judges within the state and federal judicial systems. With reference to patient care activities, these court decisions may offer guidance in defining acceptable conduct, negligence, and the interpretation of state statutes and regulations that apply to EMS.
- **Criminal law** is a type of law in which the federal, state, or local government prosecutes individuals for violating a law. Criminal laws are enacted to protect society (a "public" complaint). Violation of criminal law may be punishable by fine or imprisonment or both.
- **Civil law** (tort law) deals with "private" complaints brought by one person (the *plaintiff*) against another person (the *defendant*). These complaints are for an illegal act or wrongdoing (*tort*) for which the plaintiff asks the court to award damages. Most EMS activities that result in litigation are civil suits.

How Laws Affect the Paramedic

As previously stated, the U.S. legal system has been active on issues relating to medical malpractice. To avoid litigation, paramedics must be knowledgeable about these issues. They also must know how these issues can affect patient care activities.

SCOPE OF PRACTICE

Scope of practice for paramedics refers to the range of duties and skills they are allowed and expected to perform when necessary. These duties are set by state law or regulation. Scope of practice defines the boundaries between the paramedic and the lay person. It also defines the boundaries between professionals (e.g., EMTs, paramedics, and physicians).[2] For example, the scope of practice for most paramedics in most states includes endotracheal intubation, administration of medications, and other basic and advanced life support procedures. If a paramedic commits a scope of practice violation, it is a criminal offense.

CRITICAL THINKING
Why is it necessary to define the scope of practice for a profession?

MEDICAL DIRECTION

As is explained in Chapter 1, medical direction is a required component of paramedic practice. Medical direction may be provided online (direct) or off-line (indirect), depending on state and local requirements. EMS systems also should have a policy to guide paramedics in dealing with physicians on the scene (these physicians may be known as *bystander physicians* or *physician interveners*). Some states have cards for paramedics to give to on-scene physicians. The cards officially prohibit interference with paramedics performing their duties. The use of these cards often requires legislative or regulatory support.

LOOK AGAIN
See Chapter 1: EMS Systems: Roles, Responsibilities, and Professionalism, pp. 17-18.

MEDICAL PRACTICE ACT

A **medical practice act** is a law that governs the practice of medicine. Medical practice acts are in place to protect the public and the health care profession. This legislation varies by state. Medical practice acts may do the following:

- Designate restricted acts that prohibit certain tasks from being performed by nonphysicians
- Authorize physicians to delegate certain tasks to nonlicensed personnel
- Provide for the authorization and the withdrawal of **dependent practice;** for example, how and to what extent paramedics may perform medical acts as a function of their licensure or certification

NOTE

Dependent providers include paramedics, physician assistants, nurse practitioners, surgical assistants, certified nurse midwives, physical therapists, and other health care professionals who provide care that is within the same scope as that of physicians. Dependent providers must receive medical oversight and supervision from physicians.[3] Again, the provisions of medical practice acts vary by state.

LICENSURE AND CERTIFICATION

As is described in Chapter 1, paramedic licensure or certification (or both) may be required by state or local authorities. *Licensure* is a process of occupational regulation. In this process a government agency (e.g., a state medical board) grants permission for a person who meets established qualifications to engage in a profession. *Certification* may be granted by a governmental body (e.g., city, county, or state) or a nongovernmental certifying agency or professional association. An example of such a group is the National Registry of Emergency Medical Technicians. The terms *certification* and *licensure* often are used to refer to the same process. A certification granted by a state that confers a right to engage in a trade or profession is in fact a license.

CRITICAL THINKING

How do licensure and certification help ensure the safety of your community?

MOTOR VEHICLE LAWS

Motor vehicle laws usually define the standards for equipping and operating emergency vehicles. As do most laws, these codes vary by state. Emergency vehicle operations and motor vehicle codes are addressed further in Chapter 53.

NOTE

Criminal statutes do not always require proof of intent or intentional conduct for an action to be seen as criminal in nature. For example, an emergency vehicle crash from reckless driving may result in civil and criminal lawsuits. Excessive speed, failure to consider road and weather conditions, and improper use or nonuse of audible and visual warning devices are key areas of liability for all emergency drivers. The paramedic should be well aware of state motor vehicle codes and laws that apply to emergency vehicle operations.

MANDATORY REPORTING REQUIREMENTS

Paramedics and health care workers may be required by law to report certain cases. This is called **mandatory reporting.** Mandatory reporting usually applies to cases involving spousal abuse or abuse or neglect of children or older adults. It also include cases involving rape, sexual assault, gunshot wounds, stab wounds, animal bites, and some communicable diseases (Box 6-1). The content of the report and to whom it must be made are set by law, regulation, or policy. Local protocols set by medical direction and the EMS agency give guidance in these areas. Some states have penalties if mandatory reporting is not satisfied. Many reporting statutes provide immunity for the person reporting the situation. Immunity helps lessen the fear of legal consequences from such reporting should the report be false or unfounded. These statutes prohibit lawsuits against individuals who file reports or offer a defense in court in the event of a lawsuit.

CRITICAL THINKING

Imagine that your state requires the reporting of gunshot wounds. Your patient has a small-caliber flesh wound. The patient refuses care and begs you not to tell anyone so that her privacy will be protected. What would you do?

PROTECTION FOR THE PARAMEDIC

Some state and federal regulations provide legal protection for the paramedic. Examples include notification of exposure to infectious disease, protection provided by immunity statutes, and laws that describe special crimes against EMS personnel. These regulations vary by state and local jurisdictions.

BOX 6-1 Cases Reportable under Law in Most States

- Neglect or abuse of children
- Neglect or abuse of older adults
- Spousal abuse
- Rape, sexual assault
- Gunshot wounds
- Stab wounds
- Animal bites
- Certain communicable diseases

Notification of Infectious Disease Exposure. The Ryan White Comprehensive AIDS Resources Emergency Act of 1990 (PL 101-381) requires that emergency responders be advised if they have been exposed to infectious diseases. These diseases include hepatitis, tuberculosis, bacterial (meningococcal) meningitis, rubella (German measles), and human immunodeficiency virus (see Chapter 28). The act also requires that employers name a designated officer to coordinate communications between the hospital and the emergency response organization in case of an exposure. The responder is to be notified within 48 hours of determination of the exposure so that postexposure management procedures can be taken.

In December, 2006, the Ryan White Treatment Modernization Act of 2006 (PL 109-415) was signed into law. The part of the law in the original act that covered notification of disease exposure to first responders was stricken from the legislation. In 2009 the language that was dropped from the bill in 2006 was reinstated.[4] In addition to the Ryan White act, many states have laws that require emergency responders to be notified if they have been exposed to an infectious disease.

CRITICAL THINKING

Reflect on the time before the Ryan White law of 1990. At that time, why would some health care facilities not report significant infectious disease exposures to EMS personnel?

Immunity Statutes. Protection of state and other government entities from litigation derives from an ancient English common law. This immunity was based on the concept that "the king can do no wrong." In modern law, this means that government agencies cannot be held liable for the negligent acts of their employees. Since the 1950s, the trend in many states has been to discard this doctrine or limit its application. In some states, for example, immunity, if exercised, may apply only to the government agency and not to the individual employee or operator of an emergency vehicle. Governmental immunity statutes vary throughout the country. Therefore, EMS personnel may or may not be protected by this statute.

All 50 states have some form of **Good Samaritan laws.** The intent of these laws is to encourage people to help others in an emergency without fear of a lawsuit. As a rule, a person who gives emergency first aid in good faith, without expecting to be paid, and in a manner that another person with similar training would, is covered by these laws. However, these laws generally do not protect health care workers from acts of gross negligence, reckless disregard, or willful or wanton misconduct. The laws also generally do not apply to paid, on-duty EMS personnel.

CRITICAL THINKING

Imagine that your state has no Good Samaritan laws. Would this affect your decision about whether to stop and aid an ill or injured person while off duty?

Special Crimes Against a Paramedic. Paramedics may become victims of *assault* or *battery* while performing their duties. To deter crimes against paramedics, some localities have enacted ordinances that provide the same level of protection for EMS personnel as for law enforcement personnel. These ordinances make it illegal to harm or threaten to harm EMS crews or to obstruct patient care. The paramedic should use good judgment and work closely with the dispatch center and police so that dangerous situations can be avoided. *Paramedics must remember that if the scene is not safe and cannot be made safe, the EMS crew should retreat from the scene and not enter the area until it has been properly secured.*

The Legal Process

An injury lawsuit against a paramedic consists of a series of specific steps (Figure 6-1). The lawsuit begins with an incident in which a person feels that he or she has been injured as a result of negligent patient care. This person is the plaintiff. The plaintiff hires an attorney who conducts a case investigation to determine the merit of the complaint. The investigation may include examining patient care reports, textbooks, journal articles, and local protocols. If the attorney believes the plaintiff's case has merit, a complaint is prepared and filed in court. The complaint outlines the negligent conduct that resulted in the alleged injury. After the complaint has been filed in court, the complaint and a summons are served on the defendant, and the litigation process is initiated. The summons usually is

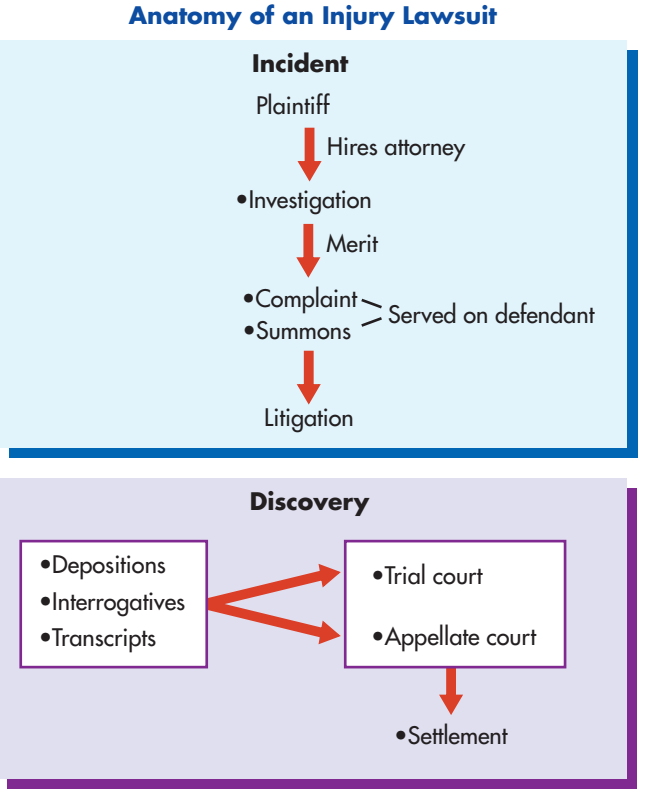

FIGURE 6-1 Anatomy of a lawsuit.

served by a sheriff or other authorized person. It requires that the defendant answer the complaint or risk automatically losing the case. At this point, the defendant and all parties involved (e.g., the paramedic, ambulance service, and hospital) usually retain an attorney to defend against the lawsuit.

The next step in the legal process is known as **discovery.** This step usually involves the exchange of documents and the taking of depositions and interrogatives. **Depositions** are testimonies taken under oath at a location other than in a courtroom. The person giving the deposition answers a list of questions from the attorney for the other side. A court reporter types the questions and answers and prepares a **transcript** that may be used during the trial. When a person gives a deposition, his or her attorney should always be present. An **interrogative** is a set of questions about the lawsuit that is answered in consultation with the party's lawyer. The interrogative then is given to the lawyer for the other side. During discovery, each side is entitled to receive all key information having to do with the lawsuit. Other documents that may be gathered during discovery are patient care reports, computer dispatch records, and recordings of radio messages related to the incident. After discovery, the case either is settled out of court or goes to trial. Quality improvement (QI) materials are "discoverable" in some states.

CRITICAL THINKING
Consider a case that occurred 5 years ago. How important would your written documentation of that case be?

During the trial, each party presents its side of the case. Based on the evidence, a judge or jury determines liability and any damages to be awarded to the plaintiff. Either side may appeal the decision of the trial court, but the appeal usually can be based only on errors in law made by the trial court.

Settlement may occur at any stage during the litigation. In settlement the plaintiff agrees to accept an amount of money in exchange for a promise not to pursue the claim. After the case is settled, it is dismissed.

NOTE
The legal process may involve both trial and appellate courts. A trial court determines the outcome of individual cases. The outcome may be determined by a judge or by a jury. The appellate court hears appeals of decisions by trial courts or other appeals courts. Decisions reached in the appellate court may set precedent for later cases of a similar nature.

LEGAL ACCOUNTABILITY OF THE PARAMEDIC

Paramedics are responsible for acting in a way that is reasonable and prudent. They should provide a level of care and transportation consistent with their education, training, and local protocol. If paramedics fail to meet these responsibilities, the result may be legal liability.

NOTE
Nearly anyone can be sued, regardless of the validity of the complaint. A lawsuit itself is not an indication of guilt or wrongdoing unless the allegations are proved.

Components of Negligence

Lawsuits involving patient care usually result from civil claims of **negligence;** that is, the failure to act as a reasonable, prudent paramedic would act in similar circumstances. In most states, four elements must be present to prove negligence: (1) a duty to act existed; (2) the actions performed were at a level that deviated from the standard of care (**breach of duty**); (3) damage to the patient or other individual (plaintiff) occurred; and (4) the breach was the proximate cause of the damage.

CRITICAL THINKING
Certain advanced life support (ALS) interventions pose a greater risk of causing harm to the patient compared with basic life support (BLS) skills. As a paramedic, what ALS interventions do you think you will perform that have this increased risk?

DUTY TO ACT

Paramedics assume a "duty" to provide emergency care when requested while working for an EMS service. This duty may be formal (contractual). The duty also may be informal (volunteer). Once a paramedic assumes the **duty to act,** the paramedic must *continue to act*. That is, the duty must not be interrupted until (1) patient care has been transferred to another health care worker whose training and experience meet the patient's needs; (2) it is abundantly clear that the patient no longer needs assistance; or (3) the patient-caregiver relationship is terminated by the patient. Among the paramedic's duties are:

- Respond and render care
- Obey laws and regulations
- Operate emergency vehicles reasonably and prudently
- Provide care and transportation to the expected standard
- Provide care and transportation consistent with the scope of practice and local medical protocols
- Continue care and transportation through to its appropriate conclusion

NOTE
The authorization of dependent practice between a physician and a paramedic may be effective only when the paramedic is on duty. Therefore, an off-duty paramedic who provides emergency care usually must act in a basic life support capacity unless the paramedic has specific authorization from medical direction to perform advanced life support procedures while off duty.

BREACH OF DUTY

As mentioned earlier, for negligence to exist, the plaintiff first must prove two of the required elements: that the paramedic had a duty to act and that the actions performed were at a level that deviated from the standard of care (breach of duty).The paramedic must exercise the degree of care, skill, and judgment that any other similarly trained paramedic would provide under similar circumstance. This **standard of care** is established by court testimony and referenced to public codes, standards, criteria, and guidelines related to the situation. Many states consider national standards when defining acceptable care. If the paramedic violated written national or state standards, the plaintiff may have a less difficult time proving breach of duty.

NOTE
The *standard of care* is a measure of competence of a professional (i.e., whether you did the right thing and did it properly). The standard of care may vary, depending on the situation; however, the scope of practice should not.[1] The standard of care differs from the *scope of practice*. The scope of practice identifies specific medical practices that are permitted by licensure, certification, or both.

Breach of duty may occur by **malfeasance** (performing a wrongful or unlawful act), **misfeasance** (performing a legal act in a manner that is harmful or injurious), or **nonfeasance** (failure to perform a required act or duty). In some cases negligence may be so obvious that it does not require extensive proof. The Latin phrase *res ipsa loquitur* means "the thing speaks for itself." This phrase implies that the facts are so clear that without a doubt the injury could have been caused only by negligence. *Negligence per se* means that negligence is shown by the fact that a statute or ordinance was violated and injury resulted.

DAMAGE TO THE PATIENT OR OTHER INDIVIDUAL (PLAINTIFF)

The third element of negligence is proof of damage; in other words, proof that the plaintiff suffered **compensable damages.** These damages may include medical expenses, lost earnings, conscious pain and suffering, and wrongful death. **Punitive damages** may be awarded in excess of compensable damages. These damages are meant to punish the person at fault and to deter others from causing such harm in the future. Punitive damages usually are not covered by malpractice insurance (this topic is discussed later in the chapter).

PROXIMATE CAUSE

Finally, the plaintiff must prove that the negligent act or lack of action caused the injury or made an existing injury worse. This is known as **proximate cause.** The plaintiff also must prove that the injury or further harm was foreseeable by the paramedic. The element of proximate cause sometimes is difficult to establish. Proof of proximate cause often calls for expert witnesses. These witnesses address issues of duty, standard of care, and conflicting views of causation. For example, was a cervical spine injury caused by the car crash or was it the result of rescue efforts by the EMS crew? Negligent conduct is possible in areas besides direct patient care. Such areas include patient transportation to a medical facility contrary to medical direction advice, trauma center designation, or other known special patient care needs and facility capabilities. Another example is failure to maintain equipment, supplies, or vehicles. Negligent or reckless driving also is an area for potential negligent conduct.

CRITICAL THINKING
Do you think an effective quality management program can reduce the risk of negligent lawsuits? Explain your reasoning.

Defenses to Negligence Claims

Several practices provide the best protection for health care professionals against claims of negligence. They include training, competent patient care skills, and full documentation of all patient care activities. The following are other defenses to negligence and their pros and cons.

1. Good Samaritan laws
   - Generally do not protect EMS personnel from acts of gross negligence, reckless disregard, or willful or wanton misconduct.
   - Generally do not prohibit the filing of a lawsuit.
   - May provide coverage for paid or volunteer EMS personnel.
   - Vary from state to state.
2. Government immunity
   - Trend is toward limiting protection.
   - May protect only government agency, not EMS personnel.
   - Varies from state to state.
3. Statute of limitations
   - Limits the number of years after an incident during which a lawsuit can be filed.
   - Is set by law and may differ for cases involving adults and children.
   - Varies from state to state.
4. Contributory negligence
   - Plaintiff may be found to have contributed to his or her own injury.

- Damages awarded may be reduced or eliminated based on the plaintiff's contribution to the injury.

SHOW ME THE EVIDENCE

A descriptive study was performed as a retrospective review of litigation against ambulance services in England over the previous 10 years. The authors found 272 cases. The most common reason given for the lawsuit was "lack of assistance or care" followed by failure or delay in treatment or diagnosis. The authors concluded that areas on which the ambulance services should focus included obstetrical care, recognition of spinal injury, and decisions not to transport.

From Dobbe A, Cooke M: A descriptive review and discussion of litigation claims against ambulance services, *Emerg Med J* 25:455-458, 2008.

LIABILITY INSURANCE

All practicing active health care professionals should have adequate liability insurance. This is also known as **malpractice insurance.** These policies offer coverage for legal defense and potential judgments against the policyholder. Malpractice insurance falls into two groups: *primary policies* and *umbrella policies.* Primary policies are personal policies. They offer certain limits of coverage for the types of risks against which the professional is insured. For example, a policy with a $100,000 limit pays up to that amount for covered damages caused by the insured.

CRITICAL THINKING

What kind of liability insurance protects you now as an Emergency Medical Technician? What type of liability insurance protects you as a student paramedic in a clinical experience?

Umbrella policies are liability insurance policies carried by employers of paramedics. For example, an ambulance service or a hospital may carry such a policy. These policies often have additional limits of coverage. These additional limits apply to on-duty employees who perform activities within the scope of practice authorized by the employer, policy, or protocol. A $1,000,000 umbrella policy, for example, covers damages caused by the insured in excess of those limits in the underlying primary policy. The amount of coverage of such umbrella policies may vary by hospital and EMS agency. The umbrella policy may not cover the employee's liability. In such a case, a separate individual policy may be desirable. A variety of companies offer the individual insurance coverage. Group plans often are less expensive, though, and may offer better coverage than the more costly individual policies.

SPECIAL LIABILITY CONCERNS

Several liability concerns are unique to prehospital care. One issue is the liability of the medical director. Another issue is the liability for "borrowed servants." Concerns also may arise relating to civil rights.

LIABILITY OF THE PARAMEDIC MEDICAL DIRECTOR

As stated earlier, paramedics function as dependent providers under medical oversight. As a result, the medical direction physician assumes legal responsibility for the patient who receives care in the prehospital setting. This is known as **vicarious liability.** This liability may hold true for actions that are performed through online medical direction. Vicarious liability also may hold true for off-line medical direction in which care is guided by the use of physician-developed protocols and standing orders. Therefore, negligence on the part of a paramedic may become the responsibility of the medical direction physician (and the paramedic's employer) even in the absence of direct supervision.

Vicarious liability arises from the relationship between the employer and employee. It also arises by virtue of the paramedic's role as a principal agent who is authorized to perform for the benefit of another. The paramedic is not an employee of the medical direction physician per se. Still, the paramedic acts as an agent in place of the physician. For this reason, the law may regard the actions of the paramedic as a legal responsibility of the medical direction physician.

LIABILITY FOR BORROWED SERVANTS

Borrowed servants is another legal doctrine. The doctrine refers to a servant who serves two "masters." An example of this is an EMT who is employed by a municipality but supervised by a paramedic. This doctrine can create liability for the supervising paramedic. It also can create liability for the employer and the medical direction physician (through vicarious liability). The amount of liability for the supervising paramedic depends on the degree of supervision and control given to the paramedic by the employer.

The borrowed servant doctrine is based on a theory that when a person has control over someone else's employee, he or she should be responsible for that person's acts. This is the case even though no employer-employee relationship exists. Paramedics who normally have full supervisory control over EMTs must protect the patient's interests by making sure the EMTs perform patient care properly.

CIVIL RIGHTS

The first civil rights measure was enacted in 1866.[5] This law prohibited discrimination based on race. Since then, civil rights laws have been modified several times to make it illegal to discriminate by reason of race, color, gender, religion, national origin and, in the case of health care, ability to pay (Box 6-2). In the case of a municipal ambulance service, a patient could bring a claim under the civil rights act for a number of possible violations in addition to discrimination. These violations could include treatment and transport without proper consent.

Another law, the Rehabilitation Act of 1973, prohibits discrimination against handicapped people solely based on the individual's handicap. This act applies to any program

BOX 6-2 Cobra and Obra

The Consolidated Omnibus Budget Reconciliation Act (COBRA) took effect in 1986. The act now is known as the Emergency Medical Treatment and Active Labor Act (EMTALA). The act addressed the medical screening, stabilization, and transfer of patients who have emergency medical conditions or who are in active labor for Medicare-participating hospitals. The act also addressed the issue of "patient dumping," which is the transfer, diversion, or premature discharge of patients from a hospital because they are unable to pay. The act set penalties of up to $20,000 for each violation. The act was amended as the Omnibus Budget Reconciliation Act (OBRA 1989, 1990, and 1993; revised 2000 and 2003).[6] This amendment clarified and strengthened enforcement of the COBRA rules. It also raised the possible fine to $50,000 per infraction. The major provisions of OBRA include the following:

- Medical screening as it relates to the capabilities of the sending and receiving hospitals
- Stabilization of the patient at a referring hospital (legal and financial responsibility)
- Provision of appropriate transfer methods after making sure the patient's condition is stable and the person has consented to the transfer
- Definition of "appropriate transfer" as the provision of the needed level of care and resources available during the transfer
- Whistle blower protection for physician and hospital staff

or activity that receives federal funding. These programs may include EMS agencies that receive Medicare or Medicaid reimbursement. Title II of the Americans with Disabilities Act also allows for equal accessibility for public services by people with disabilities. This includes receiving appropriate patient care regardless of disease condition. For example, these conditions may include acquired immunodeficiency syndrome (AIDS), infection with the human immunodeficiency virus (HIV), tuberculosis (TB), and other communicable diseases.

Protection Against Negligence Claims

Paramedics must be aware of the ways patient care activities can pose a threat of litigation for negligence. The best protections against such claims are:

- Education, training, continuing education, and skills retention
- Appropriate quality improvement
- Appropriate medical direction, online and off-line
- Accurate, thorough documentation (see Chapter 4)
- Professional attitude and demeanor

CRITICAL THINKING

Think back to a call you took as an emergency medical technician that did not go well and in which the patient did not do well. Did that call meet any of the elements of negligence? What measures could you take to prevent the recurrence of that type of situation?

PARAMEDIC-PATIENT RELATIONSHIPS

The relationship formed between the paramedic and the patient during a patient care encounter is a legal one. Consequently, legal issues may arise from the provision of patient care. These issues include confidentiality, consent (including the occasional use of force to restrain a patient), and transportation.

Confidentiality

Paramedics have a legal and ethical duty to protect a patient's privacy. Information from a patient usually can be conveyed without the patient's consent to other health care workers involved in the patient's care. For example, such information may include a history of communicable disease. Similarly, paramedics may report to law enforcement personnel and testify in court about information obtained from a patient about an incident or crime. However, potential liability for invasion of privacy and defamation (libel or slander, discussed later) exists in some cases. For example, potential liability exists in cases in which information is released with malicious intent or reckless disregard. Potential liability also exists in cases in which **protected health information (PHI)** is released to individuals not legally entitled to the information.

HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT (HIPAA)

The privacy provisions of the Health Insurance Portability and Accountability Act of 1996 (HIPAA) were published in 2003 by the Department of Health and Human Services. Compliance with the privacy rule is mandatory. The act requires all health care providers to do the following[7]:

- Protect the privacy of patients' protected health information, disclosing the minimum amount needed for treatment, billing, and operations
- Safeguard that information physically and administratively
- Grant certain rights to patients regarding that information

Compliance with HIPAA is required for all health plans (payers of health care), health care clearinghouses (facilitators of electronic data exchange between standard and nonstandard formats for payers and providers), and health care providers who conduct certain financial and administrative transactions electronically. These groups are known as *covered entities.* They must comply with certain standards regarding the protection of personal health information. They also must comply with the coding of electronic transactions. In addition, they must follow proper security measures for electronic information. EMS agencies are direct providers of health care to patients. They generate protected health records with information that identifies a person (e.g., name, Social Security number, and address). These records also contain medical information about the person (e.g., include injury or illness and treatments

provided). If EMS agencies transmit or have ever transmitted this PHI electronically in connection with any of the transactions designated under HIPAA (e.g., billing or fund transfers), they are covered entities and are subject to HIPAA regulations (Box 6-3).

DEFINITION OF CONFIDENTIALITY

Information related to a patient's history, assessment findings, and any treatment rendered generally is considered confidential information. This information can be in an electronic, a written, or a verbal format. As a rule, the release of this information for purposes other than treatment, payment (e.g., filing insurance claims), or ambulance service operations requires written permission from the patient or legal guardian. Exceptions to this general rule include the following[8]:

- Federal, state, or local law that requires release of information
- Health care fraud and abuse detection
- Certain public health activities, such as reporting a birth, death, or disease, as required by law, as part of a public health investigation; to report child or adult abuse or neglect or domestic violence; to report adverse events, such as product defects; or to notify a person about exposure to a possible communicable disease as may be required by law
- Health oversight activities, including audits or government investigations, inspection, disciplinary proceedings, and other administrative or judicial actions undertaken by the government by law to oversee the health care system
- Judicial and administrative proceedings as required by a court or an administrative order or in some cases in response to a subpoena or other legal process
- Law enforcement activities in limited situations, such as when a warrant has been issued for the request or when the information is needed to locate a suspect or stop a crime
- Military, national defense and security, and other special government functions
- To avert a serious threat to the health and safety of a person or the public at large
- Workers' compensation purposes and in compliance with workers' compensation laws
- Coroners, medical examiners, and funeral directors who need information to identify a deceased person, determine the cause of death, or to carry out their duties as authorized by law
- Organizations that handle organ procurement or organ, eye, or tissue transplantation (if the patient is an organ donor), or to an organ donation bank, as necessary to facilitate organ donation and transplantation
- Research purposes (subject to strict oversight)
- Patients who are inmates or in the custody of a law enforcement official, as needed (1) for the correctional institution to render health care; (2) to protect the patient's health or the health and safety of others; or (3) for the safety and security of the correctional institution or law enforcement

In some cases, confidential patient information may need to be released without the patient's consent. The paramedic must adhere to all reporting requirements and procedures established by state and local laws, the EMS agency, and medical direction. Even then, only the minimum necessary details should be released.

IMPROPER RELEASE OF INFORMATION

Improper release of confidential information or the release of inaccurate information can result in liability. Liability may come into play in two areas, invasion of privacy and defamation (libel and/or slander).

Invasion of Privacy. Invasion of privacy is the release, without legal justification, of details about a patient's private life that might expose the person to ridicule, notoriety, or embarrassment. For example, a paramedic is caring for a public official who was in a car crash. After the call the paramedic tells everyone at the ambulance base that the

BOX 6-3 Health Insurance Portability and Accountability Act (HIPAA)

The privacy provisions of the Health Insurance Portability and Accountability Act of 1996 (HIPAA) were published in 2003 by the U.S. Department of Health and Human Services. Compliance with the privacy rule is mandatory. The act requires all health care providers to do the following:

- Protect the privacy of patients' protected health information, disclosing the minimum amount needed for treatment, billing, and operations.
- Safeguard that information physically and administratively.
- Grant certain rights to patients regarding that information.

Compliance with HIPAA is required for health plans (payers of health care), health care clearinghouses (facilitators of electronic data exchange between standard and nonstandard formats for payers and providers), and health care providers who conduct certain financial and administrative transactions electronically. These groups are known as *covered entities.* They must comply with certain standards regarding the protection of personal health information. They also must comply with the coding of electronic transactions. In addition, they must keep proper security measures for electronic information.

EMS agencies are direct providers of health care to patients. They generate protected health records that have information that identifies a person (e.g., name, Social Security number, and address). These records also contain medical information about the person, such as an injury or illness and the treatments provided. If an EMS agency transmits or has ever transmitted this protected health information electronically in connection with any of the transactions designated under HIPAA (e.g., billing or fund transfers), it is a covered entity and is subject to HIPAA regulations.

Modified from National EMS Data Analysis Resource Center: *The application of HIPAA privacy to emergency medical service providers.* www.nedarc.org/HIPAA/hipaa_and_ems.htm. Accessed June 8, 2003.

official had a Nazi tattoo on his left shoulder. A custodian at the base hears the discussion and tells his wife, who works at the official's office building. The next day, a flyer is distributed with a caricature of the official in the back of an ambulance with this tattoo. Within a few days, the EMS agency is contacted by the official's attorney, who claims an invasion of privacy. (The fact that the information released is true is not a defense for invasion of privacy.)

NOTE

Invasion of privacy is different from defamation. In most cases of invasion of privacy, the information is true, but it is information a person wants to keep private. Defamation causes injury to reputation, whereas invasion of privacy causes injury to feelings.[9]

CRITICAL THINKING

Have you ever been in a situation in which you or a colleague said something about a patient that you think may have violated confidentiality? What did you do about it?

Defamation. **Defamation** refers to making an untrue statement about someone's character or reputation without legal privilege or the person's consent. **Libel** refers to false statements about a person made in writing or through the mass media with malicious intent or reckless disregard for the falsity of the statements. **Slander** refers to false verbal statements about a person made with malicious intent or reckless disregard for the falsity of the statements. If the paramedic in the previous example had lied about the official's tattoo, he or she and the office worker who made and distributed the flyer could be sued for libel and slander.

NOTE

In defining a defamatory statement, the courts have looked to whether the statement exposed the plaintiff to public hatred, contempt, ridicule, or degradation. Proof must exist of actual harm to the person's reputation.[8]

Consent

The rights of patients have been defined and clarified by legislation and by the judicial system through malpractice litigation. A basic concept of law and medical practice is a patient's rights. These involve the **decisional capacity** of patients and their right to choose what medical care and transport to receive.

CRITICAL THINKING

Imagine being called to care for a patient who clearly is having signs and symptoms of a heart attack but is alert and refusing care. How would you feel? What strategies would you use to try to persuade the patient to allow you to provide care and transport?

To give consent, the patient must be of legal age and must be able to make a reasoned decision about the following:

- Nature of the illness or injury
- Treatment recommended
- Risks and dangers of treatment
- Alternative treatments and associated risks
- Dangers of refusing treatment (including transport)

SHOW ME THE EVIDENCE

A study was done on whether paramedics can safely decide which patients do not need ambulance transport. Paramedics at a New Mexico EMS service were asked (before transport) to predict whether their patient could be transported by means other than ambulance. The paramedic's opinion was compared to the patient's emergency department differential diagnosis. Of the 236 calls evaluated, the paramedics thought 53% of the patients could have been transported by other means. Of that group, 24% needed ambulance transport (as defined by the study criteria). Paramedics were likely to undertriage patients in three situations; all involved abnormal vital signs, but also an unremarkable chief complaint, intoxication, or psychological problems. The authors concluded that the paramedics in the study group were not capable of making nontransport decisions safely or accurately.

From Hauswald M: Can paramedics safely decide which patients do not need ambulance transport or emergency department care? *Prehosp Emerg Care* 6:383-386, 2007.

TYPES OF CONSENT

Informed consent is patient consent that signifies the individual knows, understands, and agrees to the care rendered. This consent is given based on full disclosure of the information. Verbal or written consent to the treatment is called **expressed consent.** (Consent also can be expressed nonverbally by actions or simply by the patient allowing care to be provided.)

NOTE

Consent generally must be obtained before treatment is initiated. However, paramedics do not have to obtain the same degree of informed consent as other health care personnel. For example, in-hospital staff members must obtain a higher degree of consent. Because the paramedic is working in an emergency situation, the patient must only agree or at least must not object to the general nature of the treatment.

Implied consent presumes that an unconscious person without decisional capacity who needs emergency care would consent to lifesaving care if able to do so. Unconscious patients and victims of shock, head injury, and alcohol or other drug intoxication are examples of patients to whom emergency care should be provided in the absence of informed consent. It should be noted, however, that an adult with decisional capacity who regains consciousness can revoke consent at any time during care and transport. This commonly is seen in situations involving diabetic patients and those with seizure disorders who may choose to refuse ***insulin*** or anticonvulsant medicines.

Involuntary consent refers to treatment that is granted by the authority of law. An example is caring for patients who are held involuntarily for mental health evaluation. Another example is patients who may be held under arrest or who are in protective custody. The paramedic must follow established policies and procedures when providing care to these patients. (Law enforcement personnel may not order a paramedic to treat a patient who has decisional capacity and who objects to the treatment.)

SPECIAL CONSENT SITUATIONS

Situations may arise in which obtaining consent for treatment is difficult. Such cases may involve minors, adults without decisional capacity, patients in an institution, or prisoners. In such cases, consent for medical care may need to be obtained from a parent, legal guardian, representative of a state agency, or other legal authority. If a delay in obtaining consent would pose a threat to the patient's life, however, the person should be treated. EMS personnel should be familiar with state laws governing these unique circumstances and should follow agency protocols. When a situation arises with consent issues, paramedics should *always* make sure medical direction is contacted and involved in the decision-making process, and they should carefully document all events.

Minors. In most states a person is a minor until age 18. This is the case unless the person is emancipated. **Emancipation** is the legal release of an individual from parental control and supervision. Emancipation may include minors who are married, who are parents, who are in the armed forces, and who are living independently and are self-supporting. An example of the latter is college students who do not live at home or do not receive financial aid.

Unemancipated minors are those who are under parental control and supervision. These minors are not legally able to give or withhold consent (although consent should be sought before treatment). The consent of a parent, legal guardian, or court-appointed custodian usually is required. If a delay in obtaining consent would pose a threat to the minor's life, the emergency doctrine of treating and transporting the patient without consent applies. Although the courts will assume that the parents would have consented, the paramedic should thoroughly document the nature of the emergency and the reason the minor required urgent care.

Adults Without Decisional Capacity. With regard to obtaining consent, providing emergency care for adults without decisional capacity is similar to caring for minors. These patients may not be able legally to give or refuse consent. Decisional capacity may be impaired by a number of factors, such as disease, injury, anxiety, mental illness, mental retardation, and alcohol or other drug use. The patient may not be mentally or emotionally able to make sound decisions about his or her care. Therefore, the emergency doctrine of treating and transporting without consent should be applied. Emergency care should be provided without consent only when a life-threatening illness or injury exists and only when a legal guardian is not present to grant or refuse consent. The paramedic should involve medical direction in these decisions.

Prisoners or Arrestees. Incarceration or detention generally does not deny a person the right to make choices about medical treatment. However, a prisoner or arrestee may have a limb- or life-threatening injury or illness and may refuse to give consent. In these cases, the court or law enforcement agency that has the patient in custody sometimes may authorize treatment. The authority of law provides consent through the emergency doctrine. Paramedics who often provide care in prison settings should be aware of local and state laws regarding consent for this population.

Refusal of Care or Transport. An adult with decisional capacity has the right to refuse medical care. This is true even if the choice could result in death or permanent disability. Refusal of care may be based on religious beliefs, inability to pay, fear, or lack of understanding of medical procedures. Paramedics should be sensitive to these concerns; they should explain each procedure carefully and answer any questions the patient has. Documentation of this effort on the patient care report is prudent.

NOTE

When a patient refuses care or transport, the paramedic should try to ensure that the patient has decisional capacity. The following steps may be helpful:

1. Make a visual assessment that includes responsiveness, level of consciousness, orientation, obvious injuries, respiratory distress, and gait.
2. Make an initial assessment to evaluate airway, breathing, circulation, and disability.
3. Measure vital signs, including pulse, blood pressure, and respiratory rate and effort. Use pulse oximetry or blood glucose testing (or both) when clinically indicated.
4. Perform a focused examination as dictated by the patient's complaint (if any).
5. Make sure the patient understands the nature of his or her condition and the medical consequences of the patient's medical care decision.
6. Consult with medical direction and thoroughly document the event.

Involving medical direction, law officers, family members, and friends at the scene may help persuade the patient to accept care and transportation. Despite these efforts, however, some patients still refuse care. If this occurs, the paramedic should make sure before leaving that the patient understands that he or she can call again for help despite the initial refusal. In addition, family members or friends should be encouraged to stay with the patient, if possible. Cases involving refusal of care are a major cause of lawsuits against EMS agencies. The paramedic should always consult with medical direction about these cases.

When attempting to provide care to any patient who refuses care, the paramedic should thoroughly document the event. The names and addresses of others who witnessed the event should be recorded, as should all attempts to obtain consent. In addition, the paramedic should advise the patient of the medical risks of refusing care and record this advice on the patient care report (PCR). Law enforcement officers and other allied health professionals at the scene should be asked to make similar records of the event. Many EMS systems require the paramedic to obtain a "release of liability" signed by the patient and a disinterested witness. The release should note the refusal of care or of transportation, or both (Figure 6-2).

Some EMS systems require EMS crews to contact medical direction while at the scene. At that time, the paramedics review the case with the physician or physician designee. Medical direction personnel may discuss the situation with the patient while the call is recorded. This policy may be useful in suppressing legal action. However, the most critical legal document of refusal is the written PCR prepared by the paramedic.

LEGAL COMPLICATIONS RELATED TO CONSENT

Four other key legal issues are related to consent: abandonment, false imprisonment, assault, and battery. These may result in a civil or criminal violation.

Abandonment. Abandonment is the improper termination of care or the turning over of care to personnel without the training and expertise appropriate for the patient's medical needs. Abandonment may occur at the scene or when the patient is delivered to the emergency department (ED). Examples include allowing an emergency medical responder (EMR) to provide care for a patient who requires advanced life support care and placing a patient in critical condition in the care of an unlicensed ED "tech" at the receiving hospital.

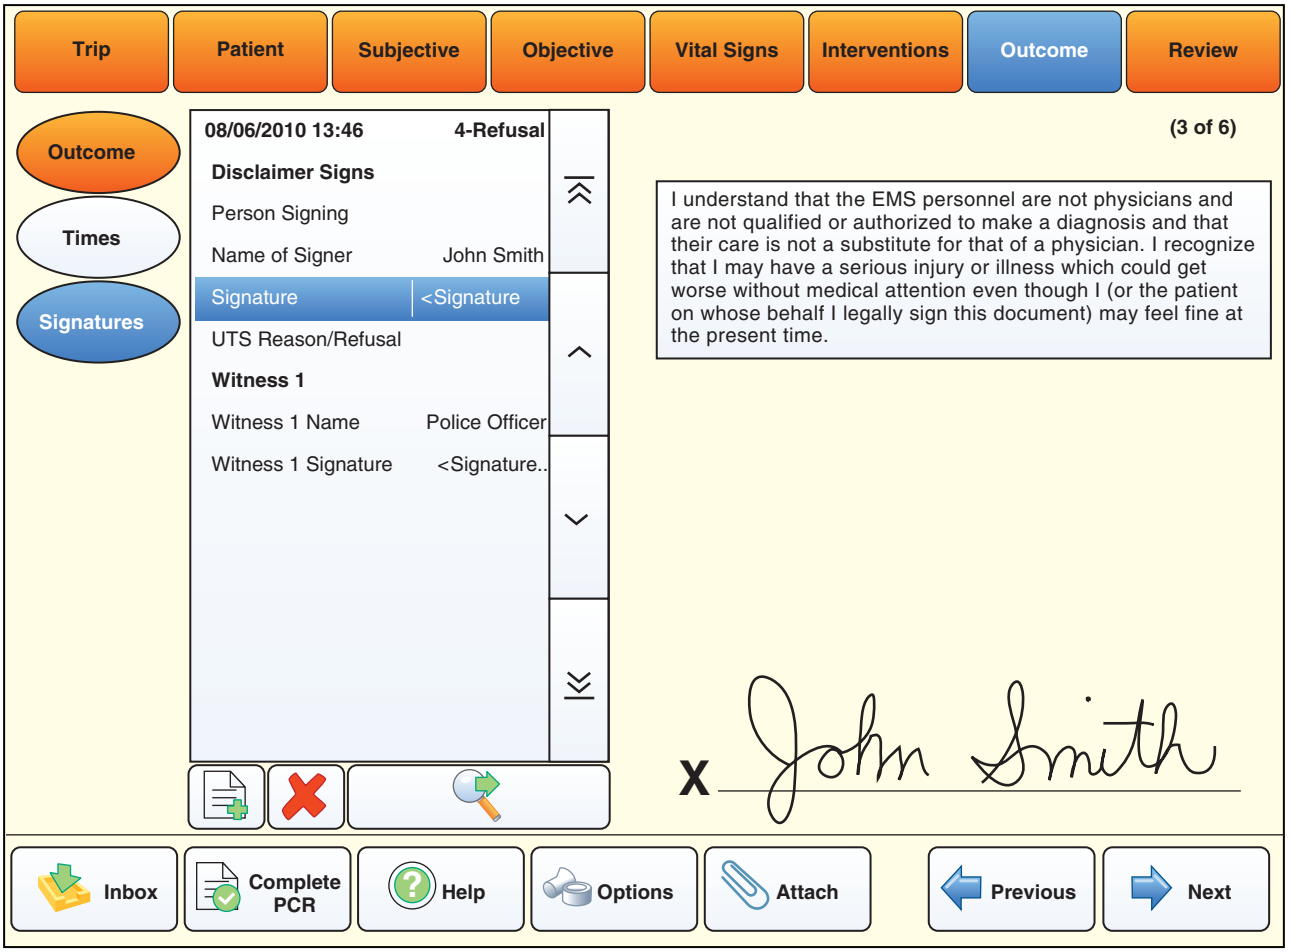

FIGURE 6-2 Electronic refusal form.

False imprisonment. **False imprisonment** is the intentional and unjustifiable detention of a person. Examples include charges brought by a patient who was transported without consent or who was restrained without proper cause or authority.

Assault. **Assault** is the creation of apprehension or the unauthorized handling and treatment of patients. An example is threatening to restrain a patient unless the patient "quiets down."

Battery. **Battery** refers to physical contact with a person without the individual's consent and without legal cause. An example is drawing a patient's blood without permission or authorization.

The paramedic can prevent problems in these other areas of liability by using good judgment. In addition, the paramedic must be sensitive to any special needs of the patient in crisis. Unusual situations or actions should be recorded on the PCR. Medical direction and law enforcement should be involved when needed.

Use of Force

Occasionally, reasonable force or restraints may be needed to deal with unruly or violent patients. These patients may be unable to make sound decisions about their care. An example is a patient with a behavioral emergency. Another example is a patient with an altered level of consciousness caused by injury, substance abuse, or illness.

Most law enforcement agencies have the authority to place a patient in protective custody, thereby permitting some patients to be treated. EMS personnel should become involved in restraining patients only when it can be done safely and there is reason to suspect that patients are a threat to themselves or others. Agency protocols should be followed when restraint of patients is necessary. Some protocols require that violent patients be put in protective custody by law enforcement personnel before paramedics become involved in patient care. The use of reasonable force to restrain a patient must always be humane and should never be punitive. (Physical restraint and the use of sedative drugs [chemical restraint] to help subdue a patient are described in Chapter 35.)

Transportation

As previously stated, once the paramedic has assumed the duty to act and has begun patient care, the paramedic must continue care until (1) the patient is transferred to another health care worker with training and expertise appropriate for the patient's medical needs; (2) the patient clearly no longer needs care; or (3) the patient ends the patient-caregiver relationship. A key aspect of this continuum of care is patient transport.

USE OF EMERGENCY VEHICLE OPERATING PRIVILEGES

In operating the emergency vehicle, the driver must conform to laws, regulations, and policies. The driver also must operate the vehicle in a manner that safeguards the patient, crew, and public. Operators of emergency vehicles usually are given right-of-way privileges, allowing the driver to do the following:

- Travel slightly faster than the posted speed limit
- Move safely from one lane into the opposite lane of traffic
- Safely enter and pass through intersections on a red light
- Use audible and visual warning devices appropriately
- Park in unauthorized areas

CRITICAL THINKING

Your supervisor decides that exceeding the posted speed limit (even with audible and visual warning devices) is too dangerous to the community. The supervisor disallows it on all but cardiac arrest calls. What do you do?

Paramedics should be aware of the laws in their state regarding right of way and should not abuse these privileges. Excessive speed and improper use of audible and visual warning devices are examples of privileges that sometimes are abused. Most states recommend that emergency vehicles not exceed the posted limits more than 10 miles per hour during response or patient transport[10] (see Chapter 53).

CHOICE OF PATIENT DESTINATION

The choice of hospital to which the patient is taken should be based on the patient's needs and the hospital's capability. If possible, the paramedic should honor the patient's choice. Examples of limitations on hospital selection include hospitals on diversion status because of patient load and the need for specialty care that can be provided only at designated facilities (Box 6-4). Protocols for hospital selection must be established. In addition, medical direction should be involved when a patient's choice of hospital cannot be honored. For example, some EMS agencies use a "nearest hospital" rule. This may be the case even if the nearest hospital is not the facility requested by the patient.

PAYER PROTOCOLS

In some cases health care plan restrictions may affect when and where a patient can be taken for medical care. For example, Medicare, which is the largest single payer of ambulance services in the United States,[11] has complex rules about the types of services and patient transports that are eligible for reimbursement. Paramedics must have a basic understanding of these programs so that the EMS agency can be paid for its services. In addition, such knowledge helps paramedics help patients determine which services are likely to be covered by their insurance policies.

In emergencies involving a threat to life or limb, payer protocols should not be a factor in providing patient care or transportation to the closest appropriate facility. However, the paramedic must provide a full description of patient care activities on the patient care report. This is

BOX 6-4 Categorization of Hospital Resource Capabilities

The American Medical Association recommended categorization of hospital emergency services in the early 1970s. In 1990 a task force of the American College of Surgeons' Committee on Trauma published *Resources for Optimal Care of the Injured Patient* (which was revised in 1999 and amended in 2000 and 2006). The publication described three levels of trauma centers based on resources, admissions, staff, research, and education involvement.

- *Level I* institutions can provide total care for every aspect of injury. The trauma center is qualified to care for the most severely injured patient, especially in the surgical critical care setting.
- *Level II* institutions provide care that supplements treatment in level I facilities; they also serve as the primary care institutions in less populated areas.
- *Level III* institutions provide services such as assessment, resuscitation, emergency surgery, and stabilization. Patients may be transferred to higher level institutions as needed.

Note: The American College of Surgeons also has designated level IV facilities, which are primarily referral centers. Some states recognize level IV centers.

Categorization of hospital resources identifies hospitals capable of handling trauma patients. It also enables EMS personnel to transport patients rapidly to the correct medical facility. Based on the guidelines established by the American College of Surgeons, some state government agencies have designated certain institutions as trauma centers. Other specialized care facilities, such as pediatric trauma centers, burn centers, hyperbaric centers, and poison treatment centers, provide care for critically ill or injured patients with special needs.

In 1991 the Department of Health and Human Services and EMS division committees provided financial grants for states to develop comprehensive statewide trauma systems as part of the Trauma Systems Planning and Development Act of 1990. These grants were last awarded in 1994.

crucial; some claims are rejected for reimbursement because of poor documentation.

RESUSCITATION ISSUES

Issues involving resuscitation are complex. They often pose certain legal and ethical considerations for the patient, family, EMS crew, and medical direction. Resuscitation issues that relate directly to EMS include withholding or stopping resuscitation (termination of resuscitation [TOR]), advance directives, potential organ donation, and death in the field.

Withholding or Stopping Resuscitation

As stated previously, informed adult patients with decisional capacity have the right to refuse medical care, including cardiopulmonary resuscitation (CPR). This right does not depend on the presence or absence of terminal illness, the agreement of family members, or approval of physicians. As a rule, patients who are pulseless should be resuscitated (unless directed otherwise by a physician), until one of the following occurs[12]:

- Restoration of effective, spontaneous circulation and ventilation
- Transfer of care to a senior emergency medical professional
- The presence of reliable criteria indicating irreversible death
- The health care provider is unable to continue because of exhaustion or dangerous environmental hazards or because continued resuscitation places the lives of others in jeopardy
- A valid DNAR order is presented
- Online authorization from the medical control physician or by prior medical protocol for termination or resuscitation

According to the American Heart Association, unwitnessed deaths in the presence of known serious, chronic, debilitating disease or in the terminal state of fatal illness may be a reliable criterion in some settings to believe that CPR is not indicated. CPR also is not indicated for traumatic arrests with extended response or transport times.[12] At some emergency scenes, the paramedic may have difficulty determining whether resuscitation should be initiated. For example, a family member may request CPR for a patient despite the existence of a No CPR order (Box 6-5). In this situation (or if the paramedic suspects that the No CPR order is invalid), the paramedic should initiate resuscitation and contact medical direction.

CRITICAL THINKING

You are called to care for a debilitated older adult in full cardiac arrest. The family members tell you that they want nothing done and are sobbing and begging you not to resuscitate the patient. They do not have the written documentation needed by your agency to permit the do not resuscitate order. What do you do? How would you feel about your decision?

In most circumstances, paramedics should err on the side of providing resuscitation and life support if any issue is unclear. If evidence later indicates that resuscitation should be withheld, life support measures can be stopped.

The determination to stop resuscitation in the prehospital setting should be made by EMS authorities and medical directors, who generally should ensure the following:

- Tracheal intubation has been successfully performed.
- Intravenous access has been achieved, and rhythm-appropriate medications and countershocks for ventricular fibrillation or pulseless ventricular tachycardia have been administered according to advanced cardiac life support protocols.

BOX 6-5 Do Not Resuscitate (DNR) Orders

Orders that specify no cardiopulmonary resuscitation (CPR) attempts (i.e., do not resuscitate [DNR] and do not attempt resuscitation [DNAR]) are the result of a decision made between the patient and the physician that CPR should be withheld in the event of cardiac arrest. However, such orders do not limit other forms of treatment, such as oxygen, fluid replacement, and drug administration. Some nursing home orders specify the levels of care and support to be provided; for example, the orders may specify no intubation.

BOX 6-6 Cardiac Terminology*

Agonal: A cardiac rhythm frequently seen as the last rhythm in an unsuccessful resuscitation attempt; also called "dying heart" rhythm.

Asystole: The absence of mechanical and electrical activity in the heart.

Countershock: A high-intensity, short-duration electrical shock applied to the area of the heart.

Ventricular fibrillation/pulseless ventricular tachycardia: Pulseless rhythms of the heart.

*See Chapter 22 for a more detailed discussion of cardiac conditions.

- Persistent asystole or agonal electrocardiographic patterns are present, and no reversible causes have been identified (Box 6-6).

Advance Directives

In 1991 a federal law known as the Patient Self-Determination Act of 1990 was passed. The law required all facilities that accept Medicare or Medicaid to recognize any kind of **advance directive.** Examples of such directives are a *durable power of attorney for health care* and a *do not resuscitate order* (Figure 6-3). These legal documents are executed to inform health care personnel of a patient's wishes in the event the person becomes incapacitated and unable to convey these wishes directly. The person's wishes may include treatment or the withholding of treatment. Many states also have passed legislation regarding *living wills* and the *right to die with dignity*. These laws are for patients with a terminal illness.

The EMS service must work closely with medical direction to develop procedures and protocols that help EMS personnel contend with these laws and policies. Advance directives should not be confused with No CPR orders. Advance directives require interpretation by a physician and must be formulated into a treatment plan. This treatment plan may include No CPR orders consistent with the patient's wishes. Medical direction must establish and implement policies for dealing with advance directives.

The EMS crew may be dispatched to a dying patient who has asked not to be resuscitated. In such a case, the crew should contact medical direction immediately so that decisions can be made about the patient's care. If medical direction determines that the patient is not to receive medical intervention to prolong life, paramedics should provide reasonable measures of comfort. Emotional support to family members and loved ones also is important during this time.

NOTE

EMS and medical direction should work closely with the families and physicians of terminally ill patients in private homes and hospice programs. This allows these individuals to make appropriate use of the EMS system and to know when to call 9-1-1. Even though resuscitation may not be indicated, EMS personnel may be needed to manage pain and to treat an acute medical illness or a traumatic injury and to provide transport to a hospital. Policies must be set and adopted by local or state EMS authorities to allow people to decline resuscitation attempts but still have access to other emergency medical care and ambulance transport.

Potential Organ Donation

Each day in the United States, about 77 people receive organ transplants. However, 19 people on the waiting list die because not enough organs are available (Box 6-7).[13] The donation of organs and tissues and the transplantation process are complex. Donation and transplantation require the effort of many health care professionals. Paramedics can play a key role in the evaluation of potential donors by identifying appropriate patients, establishing communication with medical direction, and providing emergency care to help maintain viable organs.

Identifying likely donors who are dead or near dead is a vital role for EMS agencies in organ procurement. Paramedics can identify a donor by searching for a donor card (Figure 6-4). They also can look for a notation on a driver's license that indicates the person's intent to be a donor or not to be a donor. Another method is to talk with next of kin about the patient's intent to donate tissue or organs at death (Box 6-8). Even if the patient has no donor card or other document, the family still has the right to make the decision to donate. Tissue procurement organizations provide special training for EMS personnel that can teach them how to approach the family about organ donation.

Once the patient has been identified as a potential donor, paramedics should contact medical direction. Then the proper organ procurement agencies should be notified. These agencies are staffed 24 hours a day to assist in all aspects of the donation, including gathering the proper documentation. The paramedic should carefully and thoroughly record all patient care activities, vital sign assessments, and scene events (e.g., presence of drug paraphernalia) that may affect the agency's evaluation of the potential donor.

Donations usually are separated into two groups: vital, or heartbeating, donors; and the more common donor who

OUTSIDE THE HOSPITAL DO-NOT-RESUSCITATE (OHDNR) ORDER

I, _____, authorize emergency medical services personnel to
(name)
withhold or withdraw cardiopulmonary resuscitation from me in the event I suffer cardiac or respiratory arrest. Cardiac arrest means my heart stops beating and respiratory arrest means I stop breathing.

I understand that in the event that I suffer cardiac or respiratory arrest, this OHDNR order will take effect and no medical procedure to restart breathing or heart functioning will be instituted.

I understand this decision will **not** prevent me from obtaining other emergency medical care and medical interventions, such as intravenous fluids, oxygen or therapies other than cardiopulmonary resuscitation such as those deemed necessary to provide comfort care or to alleviate pain by any health care provider (e.g. paramedics) and/or medical care directed by a physician prior to my death.

I understand I may revoke this order at any time.

I give permission for this OHDNR order to be given to outside the hospital care providers (e.g. paramedics), doctors, nurses, or other health care personnel as necessary to implement this order.

I hereby agree to the "Outside The Hospital Do-Not-Resuscitate" (OHDNR) Order.

Patient – Printed or Typed Name	Date
Patient's Signature or Patient Representative's Signature	Date

REVOCATION PROVISION I hereby revoke the above declaration.	
Patient's Signature or Patient Representative's Signature	Date

I AUTHORIZE EMERGENCY MEDICAL SERVICES PERSONNEL TO WITHHOLD OR WITHDRAW CARDIOPULMONARY RESUSCITATION FROM THE PATIENT IN THE EVENT OF CARDIAC OR RESPIRATORY ARREST.

I affirm this order is the expressed wish of the patient/patient's representative, medically appropriate and documented in the patient's permanent medical record.

Attending Physician's Signature **(Mandatory)**		Date
Attending Physician – Printed or Typed Name	Attending Physician's License No.	Attending Physician's Telephone No.
Address – Printed or Typed		Facility or Agency Name

THIS OHDNR ORDER SHALL REMAIN WITH THE PATIENT WHEN TRANSFERRED OUTSIDE THE HEALTH CARE FACILITY.

Emergency Medical Services personnel shall not comply with an outside the hospital do-not-resuscitate order when the patient or the patient's representative expresses to such personnel in any manner, before or after the onset of a cardiac or respiratory arrest, the desire to be resuscitated or if the patient is or is believed to be pregnant.

FIGURE 6-3 Advance directive.

BOX 6-7 The Wait for Organ Transplantation

Every 16 minutes, a new name is added to the national transplant waiting list. The following statistics reflect the national patient waiting list for organ transplant on July 1, 2011, as reported by the United Network for Organ Sharing (UNOS). UNOS is a private, nonprofit organization that has a contract with the federal government to manage the nation's organ transplant system.

Transplant Type	Patients Waiting
Heart	3208
Heart-lung	65
Intestine	252
Kidney	95,274
Kidney-pancreas	2255
Liver	17,060
Lung	1817
Pancreas	1387
Total	121,318*

*UNOS policies allow patients to be listed with more than one transplant center (multiple listing); therefore the number of registrations is greater than the actual number of patients. Also, some patients are waiting for more than one organ; therefore, the total number of patients is lower than the sum of patients waiting for each organ.

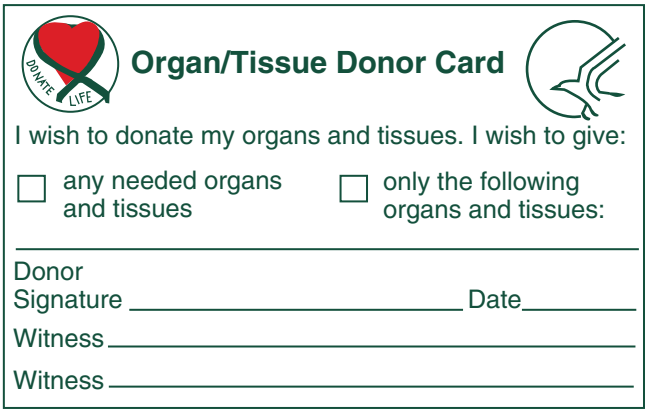

FIGURE 6-4 Organ donor card.

BOX 6-8 Legal Next of Kin

When a patient dies in the prehospital setting, organ and tissue donation should be offered as the final option to the surviving family members. This option should be offered regardless of the decision to transport the patient to the hospital. Obtaining consent for organ or tissue donation is a delicate subject. The paramedic should approach the issue with compassion and in a positive manner. When approaching a family for organ donation, the paramedic must obtain consent from the next of kin. This relationship is defined by law. The accepted legal order is as follows:

1. Spouse (even if separated but not divorced)
2. Adult son or daughter (over age 18)
3. Parents (for any unmarried child)
4. Siblings (in the event both parents are deceased and the donor is unmarried or divorced with no adult children)
5. Legal guardian

has no heartbeat (nonvital tissue donor). Vital donors may donate the heart, liver, kidneys, lungs, and pancreas. These donors must meet the criteria for brain death (Box 6-9). In addition, the donor's heartbeat and circulation must be maintained until the vital organs have been harvested. The nonvital (no heartbeat) tissue donor can donate corneas, skin, bones, tendons, heart valves, and saphenous veins up to 24 hours after cardiac death.

The paramedic plays a key role in helping to maintain viable organs in the prehospital setting by preserving organ function. This is accomplished by airway management and by proper fluid resuscitation to maintain blood pressure and organ perfusion (see Chapter 36). For all nontransported individuals who die at the scene, eye care should be provided using lubrication and saline solution or a commercial product (e.g., Lacri-Lube). In addition, the eyes should be taped closed so that donation of the cornea can continue to be an option for the family.

Death in the Field

Policies for determining death in the field should be established by medical direction in accordance with state and local protocols. Determination of death usually is confirmed by the following signs:

- No spontaneous electrical activity in the heart, as confirmed by an electrocardiogram in several leads
- No spontaneous respirations
- Absent cough and gag reflex
- No spontaneous movement
- No response to painful stimuli
- Fixed and midpoint pupils

Other signs also used to determine death include the presence of dependent lividity and rigor mortis (Box 6-10). When paramedics encounter an apparent death in the field, they should do the following:

- Contact medical direction and follow established state and local protocols
- Document any observations or unusual findings at the scene
- Notify appropriate authorities per protocol (e.g., the police and the coroner)
- Disturb the scene as little as possible
- Provide emotional support to surviving family members and loved ones at the scene

BOX 6-9 Criteria for Brain Death

Brain death has been defined as the state of an individual who has sustained either (1) irreversible cessation of circulatory and respiratory functions or (2) irreversible cessation of all functions of the entire brain, including the brain stem.[14] These clinical findings usually are confirmed in the hospital by electroencephalogram or a brain flow scan. In most states, brain death must be declared by two separate physicians, and neither physician can be involved in the removal or transplantation of the organs.

BOX 6-10 Physiological Changes That Occur after Death

Within minutes after death, postmortem changes begin to occur in the body. The surface of the skin becomes pale and yellowish; body temperature falls and reaches that of the environment within 24 hours; blood pressure and muscle tension decrease; and the pupils become dilated. Blood and fluids begin to drain away from the face, nose, and chin as gravity causes blood to settle in the most dependent (i.e., lowest) tissues. This drainage results in a bluish purple discoloration in the tissues known as *postmortem lividity.*

Within 6 hours after death, muscle stiffening occurs as a result of chemical changes in the body. This is known as *rigor mortis.* Smaller muscles in the face usually are affected first. Rigor mortis is followed by a stiffening of the entire body within 12 to 14 hours. Signs of tissue decay usually are obvious within 24 to 48 hours after death, depending on environmental temperatures. Rigor mortis diminishes and the body becomes flaccid within 12 to 14 hours. As the body decays, the skin loosens from the underlying tissues, and swelling and bloating become evident.

CRIME SCENE RESPONSIBILITIES

Paramedics play two important roles in the management of crime and other incident scenes. The first is to provide patient care (the primary focus). The second is to help preserve evidence at the scene when possible. Personal safety always is the first priority in any emergency response. If the scene is not safe and cannot be made safe, the EMS crew should not enter the area until it has been secured by the appropriate personnel.

CRITICAL THINKING

Consider this scenario: At the scene of a shooting, you see a patient with slow, gasping respirations; however, the police will not let you enter the crime scene. How do you think you would feel? What would you do?

When responding to a crime scene, paramedics should be in direct radio communication with law enforcement officers at the scene. This provides the paramedics with information on scene safety, the number of patients, and the need for additional resources, which may include more EMS vehicles or personnel, air medical transport, fire service or specialized rescue units, and hazardous materials teams. If the police are not on the scene or if the EMS crew is the first to respond, paramedics should maintain contact with the dispatch center so that appropriate information can be relayed to law enforcement officials. Paramedics must always keep in mind that law enforcement officers are in charge of the crime scene; paramedics are in charge of patient care. EMS crews should work closely with law enforcement officers, who also provide protection for the EMS crew.

BOX 6-11 Crime Scene Preservation

Lifesaving procedures always take precedence over forensic considerations. However, the paramedic should disturb the scene as little as possible so as to help preserve evidence. Some forensic considerations include the following:

- Park the ambulance away from skid marks, tire prints, or other evidence.
- Follow the same path to and from the ambulance and patient.
- Avoid stepping on blood stains.
- Do not touch or move weapons or other environmental clues unless absolutely necessary for patient care.
- Document the exact condition of the patient and the wound's appearance on arrival at the scene, including the environment of the patient and the body's position in relation to objects and doorways.
- If possible, cut or tear clothing along a seam to avoid altering tears made by a penetrating object. Do not cut through a hole made in the clothing by a wounding object.
- Do not shake clothing; keep all clothing in a paper bag rather than a plastic bag that may alter evidence; do not give clothing to the victim's family members.
- Save any avulsed tissue for forensic pathological examination.
- If a bullet is retrieved, place it in a padded container to prevent marring and secure the evidence until it is delivered to the authorities; obtain a receipt.
- Document any dying declarations made by patients.
- Report all actions and alterations made to the crime scene to the police.

In addition to providing patient care, the paramedic should observe and document the overall scene and make an effort to protect potential evidence (Box 6-11). Steps for ensuring scene safety include the following:

- Approach the scene only after it has been secured
- Approach the scene from a direction that appears safe and allows for easy exit
- Maintain constant radio contact with the police or dispatch
- Survey and assess the scene before approaching the patient
- Keep all unnecessary individuals away from the patient
- Initiate conversations with bystanders only when necessary

DOCUMENTATION

As described in Chapter 4, the PCR serves several functions. A particularly important function is providing a legal record of the patient care delivered in the field. The report also becomes a permanent part of the patient's hospital record.

LOOK AGAIN

See Chapter 4: Documentation, pp. 63-67.

In the legal professions, the general belief is that "if it was not written down, it was not done." The paramedic's record of an emergency call is one of the first items reviewed in the case of a lawsuit for negligence or malpractice. Memory is faulty. Moreover, claims may not be filed until years after an event. As a result, EMS personnel may be expected to testify to events years after they occurred. Paramedics are allowed to refer to written reports to refresh their memory about details while testifying. Therefore, accuracy and attention to detail are crucial in documentation. The characteristics of an effective PCR include the following:

- *It is completed promptly.* The PCR is a record made "in the course of business" not long after the event. Timely completion is essential to the PCR becoming part of the hospital record.
- *It is completed thoroughly.* The PCR should cover assessment, treatment, and other relevant facts. The report should paint a complete, clear picture of the patient's condition and the care provided.
- *It is completed objectively.* The paramedic should make observations and not assumptions or conclusions. The use of emotional and value-laden words or phrases should be avoided.
- *It is completed accurately.* Descriptions should be as precise as possible; the paramedic should not use abbreviations or jargon that is not commonly understood.
- *It is written so as to maintain confidentiality.* The paramedic should follow policy for the release of patient information. When possible, the paramedic should obtain the patient's consent before the release. All records, whether paper or electronic, should be stored in a secure location with access limited by department policy.

All patient care records must be maintained in a secure location at least for the duration of the statute of limitations. This statute varies by state from 2 to 6 years for personal injury lawsuits. Patient records involving minors may have to be kept for a longer time, because the statute of limitations may not begin until the minor is 18 years of age. (This also varies from state to state.)

CRITICAL THINKING

Think back to the first call you were on when a patient refused medical care. Can you remember exact details of his level of consciousness, what you told him about the risks of refusing care, and what you told him to do if the problem got worse? Do you think all those facts are in the written documentation of that call in the event of litigation?

SUMMARY

- The structure of the legal system in the United States is composed of five types of law: legislative law, administrative law, common law, criminal law, and civil law. The law requires that paramedics perform within their scope of practice and follow all legal guidelines applicable to their practice.
- To safeguard against litigation, paramedics must be knowledgeable about legal issues. They also must know about the effects of these issues.
- Paramedics and health care workers may be required by law to report some cases. These include cases of abuse or neglect of children and older adults and spousal abuse. They also include cases involving rape, sexual assault, gunshot wounds, stab wounds, animal bites, and some communicable diseases.
- Some states and federal agencies require notification of EMS personnel of exposure to infectious disease. Also, some states have passed immunity statutes, as well as laws that describe special crimes against EMS personnel.
- Lawsuits related to patient care usually result from civil claims of negligence. This refers to the failure to act as a reasonable, prudent paramedic would act in such circumstances.
- Most legal authorities stress that protection against claims of negligence has three elements: the first is training; the second is competent patient care skills; and the third is full documentation of all patient care activities.
- For the most part, confidential information includes any details about a patient that are related to the patient's history. Any assessment findings also are included, as is any treatment given. As a rule, the release of these details requires written permission from the patient or legal guardian. (There are some exceptions.)
- A mentally competent adult with decisional capacity has the right to refuse medical care. This is true even if the decision could result in death or permanent disability.
- Four legal complications related to consent are abandonment, false imprisonment, assault, and battery.
- An adult patient with decisional capacity has certain rights. The patient has the right to decide what medical care (and transportation) to receive. This is a basic concept of law and medical practice.
- Legal responsibility for the patient continues until patient care is transferred to another member of the health care system or the patient clearly no longer requires care. Legal issues related to patient transport include the level of care during transportation, use of

Continued

the emergency vehicle operating privileges, choice of patient destination, and payer protocols.
- Resuscitation issues that relate directly to EMS personnel include withholding or stopping resuscitation, advance directives, potential organ donation, and death in the field.
- EMS personnel play two important roles when responding to a crime scene: focusing on patient care and preserving evidence at the scene when possible.
- In the legal field, the general belief is that "if it was not written down, it was not done." Therefore, thoroughness and attention to detail are vital in documentation.

CHAPTER

7 Ethics

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Define ethics and bioethics.
2. Distinguish between professional, legal, and moral accountability.
3. Outline strategies for resolving ethical conflicts.
4. Describe the role of ethical tests in resolving ethical dilemmas in health care.
5. Discuss specific prehospital ethical issues, including the allocation of resources, decisions surrounding resuscitation, confidentiality, and consent.
6. Identify ethical dilemmas that may arise with regard to care in futile situations, the obligation to provide care, patient advocacy, and the paramedic's role as physician extender.

KEY TERMS

autonomy The principle of self-determination; that is, a person's ability to make moral decisions, including those affecting personal medical care.

beneficence A duty to confer benefits; the practice of good deeds; an obligation to benefit others or to seek their good.

bioethics The systematic study of moral dimensions, including the moral vision, decisions, conduct, and policies of the life sciences and health care.

ethics The discipline relating to right and wrong, moral duty and obligation, moral principles and values, and moral character; a standard for honorable behavior designed by a group with expected conformity.

morals Social standards or customs; dealing with what is right or wrong in a practical sense.

unethical Conduct that fails to conform to moral principles, values, or standards.

Ethical dilemmas will always be a part of prehospital care. At times paramedics must perform duties that may involve conflicts in moral judgment. Examples include issues of patient confidentiality, patient's rights, and honoring a do not resuscitate order. Such ethical issues are dynamic. The ethical dilemmas of today may be decided by law tomorrow.

(Courtesy Ken Hines, Columbia, Mo.)

ETHICS OVERVIEW

Ethics is the field relating to right and wrong, duty and obligation, principles and values, and character.[1] Ethics is a basis for honorable actions designed by a group with expected conformity. **Morals** refer to social standards or customs, or dealing with what is right or wrong in a practical sense. The term **unethical** refers to conduct that fails to conform to these moral principles, values, or standards.[2] Ethical decisions are based on an appraisal of moral judgments—a concept that places the responsibility on individuals.

DID YOU KNOW?

The Difference Between Morals and Ethics

The difference between morals and ethics can seem confusing. The two concepts have similarities, but a basic, subtle difference exists. *Morals* define personal character. *Ethics* stresses a social system in which those morals are applied. In other words, ethics points to standards or codes of behavior expected by the group to which a person belongs. This could be the ethics of a social group, a religion, a company, a profession, or even a family. Therefore, although a person's moral code usually is unchanging, the ethics that the person practices can depend on the groups to which he or she belongs.

To help clarify the difference between morals and ethics, consider the following examples:

- *Example 1:* A defense attorney must defend a man she believes is guilty of murder. The attorney believes that murder is wrong and immoral and that this person would be a danger to society if found not guilty and released. However, the legal system and the ethics of the profession to which she belongs require that her client be defended as vigorously as possible. He also must receive a fair trial. In this case, the attorney's ethics must override her personal morals.
- *Example 2:* You teach your child that it is wrong to steal. That becomes the child's moral code. The fact that your child does not steal when given the opportunity is an example of the child's ethics.

The concept of ethics dates back to the ancient Greek philosophers, such as Hippocrates, Socrates, Plato, and Aristotle. They turned the focus toward questions of ethics and virtue (how one should live) for moral accountability and away from choice and fate, which traditionally had been guided by astrology. These philosophers laid the basis for a science of medical ethics (bioethics), the analysis of choice in medicine (Box 7-1).[3]

Bioethics is the systematic study of moral dimensions, including the moral vision, decisions, conduct, and policies of the life sciences and health care. Bioethics uses a variety of ethical methodologies in an interdisciplinary setting.

Many ethical and other value choices can be made instinctively, by drawing on longstanding personal beliefs, commitments, and habits. For example, most people believe it is wrong to steal, to be deceitful, or to commit murder. In health care, however, paramedics are faced with life issues that involve a patient. The patient may have beliefs, commitments, and habits that may be different from the paramedic's personal experience. Throughout history, guidance in these situations has been provided through a variety of professional codes. These codes represent the collective wisdom of a group. The EMT Code of Ethics and the American Medical Association's Principles of Medical Ethics are examples of professional codes (Boxes 7-2 and 7-3).

As with professional codes, an individual's personal code of ethics consists of principles of proper conduct. These values can help one make moral choices. A personal code is

BOX 7-1 The Earliest Hippocratic Oath

The Oath of Hippocrates is a brief statement of principles. It is thought to have been conceived during the fourth century BC. The oath protected the rights of the patient. It also addressed the moral character of the physician as a healer. The Hippocratic oath was modified in the tenth or eleventh century to eliminate reference to pagan gods. The oath remains an expression of ideal conduct for the physician.

I swear by Apollo the physician and Asclepius and Hygieia and Panaceia and all the gods and goddesses, making them my witnesses, that I will fulfill according to my ability and judgment this oath and this covenant:

To hold him who has taught me this art as equal to my parents and to live my life in partnership with him, and if he is in need of money to give him a share of mine, and to regard his offspring as equal to my brothers in male lineage and to teach them this art—if they desire to learn it—without fee and covenant; to give a share of precepts and oral instruction and all the other learning to my sons and to the sons of him who has instructed me and to pupils who have signed the covenant and have taken an oath according to the medical law, but to no one else.

I will apply dietetic measures for the benefit of the sick according to my ability and judgment; I will keep them from harm and injustice.

I will neither give a deadly drug to anybody if asked for it, nor will I make a suggestion to this effect. Similarly I will not give to a woman an abortive remedy. In purity and holiness I will guard my life and my art.

I will not use the knife, not even on sufferers from stone, but will withdraw in favor of such men as are engaged in this work.

Whatever houses I may visit, I will come for the benefit of the sick, remaining free of all intentional injustice, of all mischief and in particular of sexual relations with both female and male persons, be they free or slaves.

What I may see or hear in the course of treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things shameful to be spoken about.

If I fulfill this oath and do not violate it, may it be granted to me to enjoy life and art, being honored with fame among all men for all time to come; if I transgress it and swear falsely, may the opposite of all this be my lot.

SHOW ME THE EVIDENCE

Adams and colleagues conducted a study to identify the ethical conflicts experienced by prehospital personnel. A single observer interviewed a convenience sample of 607 paramedics.*

The authors found ethical conflicts in 14.4% of the paramedics' responses. Ethical dilemmas were related to informed consent (27%); the duty of paramedics in threatening situations (19%); requests to limit resuscitation (14%); patients' decision-making capacity (17%); resource allocation (10%); confidentiality (8%); truth telling (3%); and training (1%).

*These researchers cautioned against applying their results to the broad EMS population, because their sample was not random.

Adams J, Siminoff L, Wolfson A: Ethical conflicts in the prehospital setting, *Ann Emerg Med* 21:1259-1265, 1992.

BOX 7-2 The EMT Code of Ethics

Professional status as an Emergency Medical Technician and Emergency Medical Technician–Paramedic is maintained and enriched by the willingness of the individual practitioner to accept and fulfill obligations to society, other medical professionals, and the profession of Emergency Medical Technician. As an Emergency Medical Technician at the basic level or an Emergency Medical Technician–Paramedic, I solemnly pledge myself to the following code of professional ethics:

A fundamental responsibility of the Emergency Medical Technician is to conserve life, to alleviate suffering, to promote health, to do no harm, and to encourage the quality and equal availability of emergency medical care.

The Emergency Medical Technician provides services based on human need, with respect for human dignity, unrestricted by consideration of nationality, race, creed, color, or status.

The Emergency Medical Technician does not use professional knowledge and skills in any enterprise detrimental to the public well-being.

The Emergency Medical Technician respects and holds in confidence all information of a confidential nature obtained in the course of professional work unless required by law to divulge such information.

The Emergency Medical Technician, as a citizen, understands and upholds the law and performs the duties of citizenship; as a professional, the Emergency Medical Technician has the never-ending responsibility to work with concerned citizens and other health care professionals in promoting a high standard of emergency medical care to all people.

The Emergency Medical Technician shall maintain professional competence and demonstrate concern for the competence of other members of the Emergency Medical Services health care team.

An Emergency Medical Technician assumes responsibility in defining and upholding standards of professional practice and education.

The Emergency Medical Technician assumes responsibility for individual professional actions and judgment, both in dependent and independent emergency functions, and knows and upholds the laws which affect the practice of the Emergency Medical Technician.

An Emergency Medical Technician has the responsibility to be aware of and participate in matters of legislation affecting the Emergency Medical Technician and the Emergency Medical Services System.

The Emergency Medical Technician adheres to standards of personal ethics which reflect credit upon the profession.

Emergency Medical Technicians, or groups of Emergency Medical Technicians, who advertise professional services, do so in conformity with the dignity of the profession.

The Emergency Medical Technician has an obligation to protect the public by not delegating to a person less qualified any service which requires the professional competence of an Emergency Medical Technician.

The Emergency Medical Technician will work harmoniously with, and sustain confidence in, Emergency Medical Technician associates, the nurse, the physician, and other members of the emergency medical services health care team.

The Emergency Medical Technician refuses to participate in unethical procedures and assumes the responsibility to expose incompetence or unethical conduct of others to the appropriate authority in a proper and professional manner.

Courtesy Charles Gillespie, MD
Adopted by The National Association of Emergency Medical Technicians, 1978. http://www.naemt.org/about_us/emtoath.aspx. Accessed 4-19-11

a critical reflection on one's life. For the paramedic, a personal code of ethics must take into account professional, legal, and moral responsibilities (Box 7-4).

Professional Accountability

As professionals, paramedics conform to a standard set by their level of training and regional practice. Paramedics are accountable to the patient, the medical director, and the EMS system for meeting the standard of care. Duties include commitment to high-quality patient care; continuing education; skill proficiency; and licensure or certification or both. The paramedic is accountable by law to that level of training and that standard of care. A paramedic who is accountable to the profession is more likely to provide good patient care and make decisions that are ethically acceptable.

Legal Accountability

Through patient care activities, the paramedic also assumes a role in the health care legal system (see Chapter 6). Legal issues often are intertwined with ethical issues. However, ethics is not synonymous with law. (Ethics deals with moral actions; law deals with legal actions.) Many ethical decisions occur outside the boundaries of the law, and many legal decisions may not be ethical. An example is a patient who has a living will in a state in which the legality of advance directives has not been resolved. Another example is a terminally ill patient who requests assisted suicide in a state where the practice is illegal. The paramedic should consider the importance of legal accountability as it relates to medical ethics and abide by the law when ethical conflicts occur.

Moral Accountability

Moral accountability refers to *personal* ethics; that is, personal values and beliefs. Combining moral, legal, and professional accountability may be difficult in an emergency. At times the paramedic must draw on personal ethics to resolve conflicts among these roles and duties. Moreover, the paramedic must decide on a course of action. When dealing with ethical questions, paramedics should remember the following key points[4,5]:

BOX 7-3 American Medical Association Principles of Medical Ethics*

- A physician shall be dedicated to providing competent medical care, with compassion and respect for human dignity and rights.
- A physician shall uphold the standards of professionalism, be honest in all professional interactions, and strive to report physicians deficient in character or competence, or engaging in fraud or deception, to appropriate entities.
- A physician shall respect the law and also recognize a responsibility to seek changes in those requirements which are contrary to the best interests of the patient.
- A physician shall respect the rights of patients, colleagues, and other health professionals, and shall safeguard patient confidences and privacy within the constraints of the law.
- A physician shall continue to study, apply, and advance scientific knowledge, maintain a commitment to medical education, make relevant information available to patients, colleagues, and the public, obtain consultation, and use the talents of other health professionals when indicated.
- A physician shall, in the provision of appropriate patient care, except in emergencies, be free to choose whom to serve, with whom to associate, and the environment in which to provide medical care.
- A physician shall recognize a responsibility to participate in activities contributing to the improvement of the community and the betterment of public health.
- A physician shall, while caring for a patient, regard responsibility to the patient as paramount.
- A physician shall support access to medical care for all people.

*These principles were adopted by the American Medical Association's House of Delegates on June 17, 2001. They also have been adopted by the American College of Emergency Physicians.

BOX 7-4 Perspectives on Ethical Living

Socrates: The unexamined life is not worth living. Know thyself. Morality is the necessity of the heart. The soul is that which is.

Plato: Justice is the harmony of all virtues. Truth belongs to the mind.

Aristotle: Sense reveals only individual existence. The universal is immanent in the individual. Man finds his ethic only in his natural self-realization.

Zoroastrianism and Parsis: Good thoughts, good words, good deeds. The Reality is one, the wise by many men call it.

Buddhism: Let a man lift himself up by his own self; let him not depress himself; for he himself is his friend and he himself is his enemy.

Confucianism: Seek to be in harmony with all your neighbors.

Taoism: Being in one's inmost heart in kindly sympathy with all things.

Christianity: Love thy neighbor as thyself.

Judaism: Perform righteousness on earth that ye may find treasures in heaven.

Islam: Do what God likes, and avoid what He dislikes.

CRITICAL THINKING

Which of the perspectives on ethical living presented in Box 7-4 best speaks for your personal philosophy?

1. *Emotion may not be a reliable determinant for ethical decision making. Conscience should be monitored.* The conscience can be a reasonably good guide if one's conscience is well informed concerning right or wrong. Rational decision making relies on research and prudence to determine what is right. However, as a result of some knowledge deficit, the paramedic may come to a flawed decision.
2. *Decisions must not be based solely on the opinions of others; nor should they be based on global protocols meant to guide, not dictate (e.g., codes of the profession).* If paramedics encounter a situation with which they have not previously dealt, they are likely to make a poor or even an unethical decision. In these circumstances, paramedics should consult with medical direction, coworkers, a supervisor, or a set of guidelines or other resources. Consultation is better than limiting oneself to one's own knowledge base or principles. At times, input from patients and their loved ones can be a key source of information and can lead to a better decision.
3. *Once the ethical question has been answered, the answer becomes a "rule" to guide behavior, at least in that particular setting.* Once the rule has been identified, it should become a barrier to acting in opposition to the rule. Paramedics are expected to avoid breaking the rule without a strong reason for their actions.

DID YOU KNOW?

The Heinz Dilemma

Lawrence Kohlberg was a well-known theorist in the field of moral development. During his research, he posed a moral dilemma (called the *Heinz dilemma*) to young children and asked for a specific course of action to three scenarios. A brief description of each scenario follows.[6]

1. A woman was near death from a unique cancer. A physician had developed a drug that could cure her. The cost of the drug was $4000 per dose, but it cost the physician only $2000 to produce it. The woman's husband (Heinz) could raise only $2000. He asked the physician who developed the drug to accept the $2000 and said that he would pay the remaining $2000 at a later date. The physician refused. *Should Heinz break into the laboratory to steal the drug for his wife. Why or why not?*
2. Heinz broke into the laboratory and stole the drug. The break-in and theft were reported in newspapers the next day. A policeman (Officer Brown), a friend of Heinz, remembered seeing him the previous evening running away from the laboratory. *Should Brown report what he saw? Why or why not?*
3. Officer Brown reported what he saw. Heinz was arrested and brought to court. If convicted, he would face up to 2

years in prison. Heinz was found guilty. *Should the judge sentence Heinz to prison? Why or why not?*

Kohlberg was not interested so much in the answers to the questions in each scenario being wrong or right. He was more interested in the *reasoning* behind the participants' decisions. The responses were then classified into various stages of reasoning in his theory of moral development.

NOTE

With regard to answering ethical questions, no one knows all the answers. In addition, none of the tools or techniques work in every case to arrive at the "right" decision. Nonetheless, paramedics are accountable for personal and professional actions and decisions. Seeking counsel and guidance in such decisions is always prudent.

RAPID APPROACH TO ETHICAL PROBLEMS IN AN EMERGENCY

A method of ethical case analysis, or "rules of thumb" process, has been designed to serve as a way to deal rapidly with ethical problems in an emergency.[7] The steps of this process are as follows:

1. Ask yourself whether you have experienced a similar ethical problem in the past. If so, use that experience as a precedent for this problem and follow the previously established rule. (The paramedic must evaluate these rules periodically.)
2. If you have not already experienced a similar ethical problem, buy time for deliberation and for consulting with co-workers and medical direction.
3. If buying time for deliberation is not an option, use a set of three tests to help you make a decision[8] (Figure 7-1):
   - Test 1 (*impartiality test*): Would you accept the action if you were in the patient's place?
   - Test 2 (*universalizability test*): Would you feel comfortable having this action performed in all relevantly similar circumstances?
   - Test 3 (*interpersonal justifiability test*): Are you able to provide good reasons to justify and defend your actions to others?

The impartiality test is a good means of correcting partiality or personal bias. The universalizability test helps do away with moral decision difficulty. The interpersonal justifiability test requires that the paramedic define reasons for proceeding that others would approve. If all three tests can be answered in the affirmative, the paramedic has a fair probability that the action falls within the scope of being ethically acceptable. Even though disagreement may occur about a specific set of values, general agreement often exists about what constitutes wrong actions.

ETHICAL TESTS IN HEALTH CARE

The most basic question of ethical tests in health care is, "What is in the patient's best interest?" However, doing what is best, or what one thinks is best, is not enough to justify actions. One must determine what the patient wants. The paramedic can do this using statements by the patient (if the patient has decisional capacity) and written statements. Family input also is helpful (if the patient shows altered mental status or a lack of decisional capacity). The role of "good faith" in making ethical decisions ("Am I doing my best to help and not harm my patient?") should be balanced with the wishes of the patient and the family. The global concept of health care is providing patient benefit and avoiding harm. It recognizes and respects the patient's autonomy. The concept also recognizes the various legal issues that affect the delivery of health care (Box 7-5).

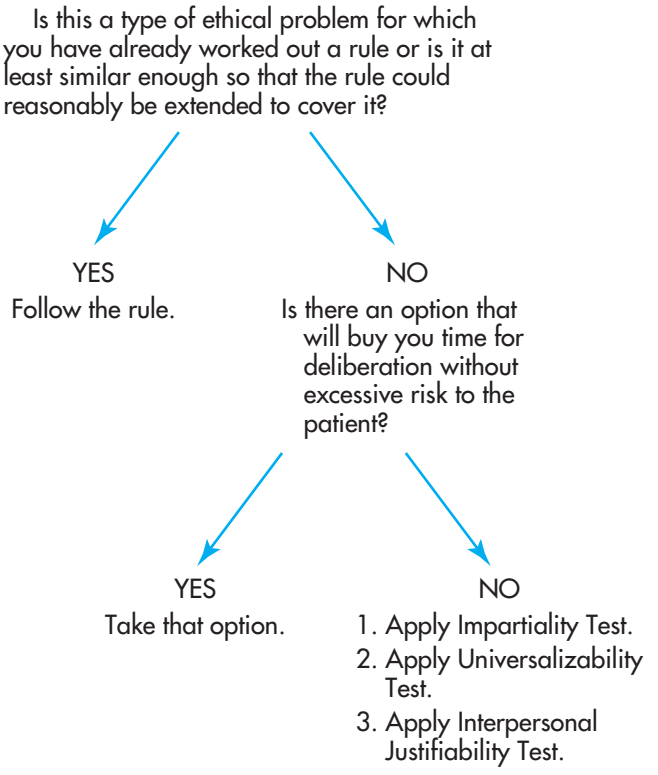

FIGURE 7-1 Rapid approach to resolving ethical problems in an emergency. (Modified from Iserson KV: *An approach to ethical problems in emergency medicine,* Baltimore, 1986, Williams & Wilkins.)

RESOLVING ETHICAL DILEMMAS

At times, ethical dilemmas can be difficult to resolve. This may be the case when global concepts of health care are in conflict. Therefore, the resolution can be guided by the health care community and by the public. The role of the health care community in resolving these conflicts is to set standards of care. The health care community also must provide research and treatment protocols. Finally, the health care community must make prospective and retrospective reviews of decisions and policies. The intent of the reviews is to educate the paramedic and improve the quality of patient care.

BOX 7-5 Global Concepts of Ethical Health Care

For an ancient Greek physician, therapeutic activity was subject to the following rules:

- Help the patient or at least to do no harm
- Refrain from interfering if the illness is incurable and inevitably mortal
- Insofar as possible, attack the cause of the disease therapeutically

Today, these global concepts of ethical health care can be stated as follows:

- Provide patient benefit.
- Do no harm.

BOX 7-6 Commonly Accepted Bioethical Values

Allocation of resources: Consistent access to quality medical services; the distribution of health-related services among various people and uses.

Autonomy: Self-determination; a person's ability to make moral decisions, including those affecting personal medical care. The three components of autonomy are *agency* (awareness of oneself as having desires and intentions and acting on them); *independence* (absence of influences that so control what a person does that it cannot be said the person wants to do it); and *rationality* (rational decision making).

Beneficence: A duty to confer benefits; the practice of good deeds; an obligation to benefit others or seek their good.

Confidentiality: The presumption that certain information will not be revealed to others without the patient's permission. Confidentiality, like privacy, is valued because it protects individual preferences and rights.

Nonmaleficence: The prevention of harm, from the Hippocratic tradition that established *primum non nocere* ("Above all, do no harm"); a prohibition against actions with foreseeable harmful effects.

Personal integrity: Adherence to a personal set of values and moral standards.

The role of the public in managing ethical conflicts in medicine includes creating laws, setting public policy, and allocating resources to protect the patient's rights. It also includes participating in the use of advance directives and other self-determination documents to make the patient's wishes known (see Chapter 6).

LOOK AGAIN
See Chapter 6: Medical and Legal Issues, pp. 102-104.

ETHICAL ISSUES IN PARAMEDIC PRACTICE

All paramedics face ethical issues during the course of their careers. Most issues deal with the patient's right to self-determination and the paramedic's duty to provide patient care (Box 7-6). The concept of the patient's right to self-determination is known as **autonomy,** and the concept of the paramedic's duty to provide patient care is known as **beneficence.** Some of the more common issues (and sample case studies) are described in this section. For each case study, the paramedic should apply the rapid approach to emergency medical problems (described previously) and answer the following ethical questions:

1. What is in the patient's best interest?
2. What are the patient's rights?
3. Does the patient understand the issues at hand?
4. What is the paramedic's professional, legal, and moral accountability?

Allocation of Resources

Fairness in the allocation of resources and obligations is a commonly accepted bioethical value. Fairness is incorporated into society-wide health care policies. This perceived "right" to universal access to an adequate level of health care is a complex economic issue that is affected by the need to contain health care costs. Two factors affect true parity in the allocation of resources. The first is a person's access to health insurance. This may define which medical services are covered or excluded. The second is treatment decisions made when resources are inadequate to meet patient care needs. This may occur, for example, during a disaster involving multiple casualties. When rationing of care is required, it should be based on ethically oriented criteria.[8]

The allocation of resources (*medical rationing*) is more of a policy than a clinical concept. However, allocation can pose ethical dilemmas in prehospital care, as illustrated in the following case study.

CASE STUDY 1

A paramedic crew has been dispatched to the home of a 74-year-old man. The man complains of chest pain and shortness of breath. The patient is in obvious distress and provides a significant cardiac history. He asks to be taken to the Veterans Administration hospital (30 miles away), where he had heart surgery several years ago. Based on the patient's history, the physical examination findings, and the electrocardiogram (ECG), the paramedic crew, in consultation with medical direction, elects to take the patient to a closer hospital so that his condition can be stabilized. The patient becomes anxious and complains of increasing chest pain. He tells the paramedic crew that he has no medical insurance and demands to be taken to the Veterans Administration hospital.

CASE STUDY 2

The paramedic crew has been dispatched to a restaurant where an elderly woman has collapsed. She has suffered cardiac arrest, and a waiter is performing cardiopulmonary

resuscitation. The ECG monitor reveals ventricular fibrillation. Defibrillatory shocks are delivered, but the rhythm remains unchanged. As resuscitation measures are continued, the woman's husband says to the paramedics, "She said she didn't want this. Her living will is at home. Please stop what you're doing and let her go."

Confidentiality

Most people are considered to have a basic right to privacy. The principle of confidentiality refers to a person's private and personal information. This information should not be disclosed by a health care professional to other people without the patient's consent. As is described in Chapter 6, doing so is illegal and may violate laws and regulations designed to protect a patient's privacy, such as state and federal laws and the regulations established by the Health Insurance Portability and Accountability Act (HIPAA).

LOOK AGAIN

See Chapter 6: Medical and Legal Issues, pp. 96-97.

In some cases, the release of such information may be required by law. An example of such a case is the disclosure to others involved in the patient's care that a patient has tested positive for infection with the human immunodeficiency virus (HIV). However, conflict between ethics and confidentiality may arise, particularly if the public health would benefit from the disclosure of confidential information, as described in the following case study.

CASE STUDY 3

The paramedic crew has been dispatched to a motor vehicle crash. A young man struck another car head-on, killing the driver of that car. The patient is shaken but has only minor injuries. As the patient is prepared for transport, he confides to the paramedic that he had used cocaine shortly before the crash. He asks the paramedic to keep the information confidential and not to tell the police officers at the scene.

CRITICAL THINKING

Your partner uses the phone number from the patient care report to contact a former patient and ask for a date. Do you think that action violates any ethical principles? If so, which ones?

CONSENT

As is explained in Chapter 6, patients with decisional capacity have a legal right to decide on the medical care they will receive. This right is a basic element of the relationship between the patient and physician and is described in the American Medical Association's Principles of Medical Ethics. The right also can be inferred from the EMT Code of Ethics. Cases in which patients refuse lifesaving care can produce legal and ethical conflicts, as shown in the following case study.

CASE STUDY 4

The paramedic crew has been dispatched to an office building where a 55-year-old woman collapsed at a business meeting. She is alert and oriented, complains of chest pain, and is pale and diaphoretic. The paramedics advise the patient of the possibility of a heart attack and the need for immediate care and transport for evaluation by a physician. The patient insists on waiting until after the meeting has concluded to seek medical care on her own, and she asks the EMS crew to leave.

OTHER ETHICAL PRINCIPLES FOR PATIENT CARE SITUATIONS

Other ethical principles of patient care arise in cases related to care in futile situations, legal obligations to provide care, patient advocacy and paramedic accountability, and the paramedic's role as a physician extender.

Care in Futile Situations

An action is seen as *futile* if it serves no purpose or is totally ineffective. A paramedic providing care in a case that may be futile should consult with medical direction. Consultation can help the paramedic decide on a course of action. An example of a futile situation in health care is continuing resuscitation initiated by bystanders when the patient clearly has expired. Another example is providing life support measures for a patient who has fatal injuries. The definition of *futility* may pose an ethical dilemma. This may be especially true when a dispute or lack of agreement exists about the goals of treatment. Not all futility judgments are controversial. For example, cardiopulmonary resuscitation is futile in patients with obvious signs of death, such as decapitation, rigor mortis, tissue decompensation, or extreme dependent lividity.[9]

CRITICAL THINKING

You arrive at a home where you find a 3-month-old baby who obviously has been dead for several hours. The mother is screaming, "Help her! Help her!" Your partner decides to proceed with advanced life support care even though it is clearly futile. Is this decision ethical?

Obligation to Provide Care

In the prehospital setting, the paramedic's duty to provide care is seldom an issue; the patient's request for emergency service presents a legal duty to act. In other areas of health care, though, an obligation to provide care other than emergency care may be affected by several factors. Examples include a patient's ability to pay for service, the patient's insurance, or other economic factors. As is described in

Chapter 6, some laws protect well-meaning caregivers from liability (e.g., Good Samaritan legislation). Other laws protect patients from unethical health care practices (e.g., the Emergency Medical Treatment and Active Labor Act [EMTALA]). An example of such practices is "economic triage," in which evaluation of the impact of the patient's care is based on fiscal aspects important to the hospital. Another example is "patient dumping," in which a patient in unstable condition is transferred or discharged from a hospital for financial reasons.

Patient Advocacy and Paramedic Accountability

While providing care, the paramedic serves as the patient's advocate. This advocacy may conflict at times with the paramedic's accountability to the patient, the physician medical director, and the health care system (e.g., health maintenance organization [HMO] protocols). In such a case, the paramedic should discuss all options with medical direction. *As a rule, it is prudent and ethical to err on the side of providing for the needs of the patient when conflict arises.* Examples of ways in which a paramedic can serve as the patient's advocate include the following:

- Educating patients about the delivery of health care and the role they can play to help change the nation's health care system
- Making sure health care decisions are made by patients and their physicians and are based on the patient's medical needs, not financial considerations
- Informing patients of health care reform initiatives in the federal, state, and private sectors
- Promoting patient access to reliable information about state-of-the-art medical technologies and treatments
- Promoting fairness and equality in America's health care system

Paramedic's Role as Physician Extender

As a physician extender, the paramedic generally is responsible for following the orders of the medical director or the director's designee. However, sometimes these orders may not seem appropriate. For example, the paramedic may believe that a medication order is contraindicated for the patient (e.g., giving narcotics when the patient is hypotensive). Also, a medication may be medically acceptable but may not be in the patient's best interest (e.g., an order for an intravenous [IV] drug to treat asthma before the patient's inhaler has been tried). A third example of such a case is a medication that is medically acceptable but morally wrong (e.g., an off-label use of a drug) (see Chapter 13).

The converse also can occur. For example, a paramedic might request treatment in a situation in which the field diagnosis is unsure, or the physician may lack information needed to approve the request. When a conflict occurs between medical direction and the paramedic, communication is the key to resolving short-term and long-term concerns.

CRITICAL THINKING

Your patient is in critical condition, and you cannot secure the airway. Medical direction tells you to divert because the hospital has no open beds in the intensive care unit. You repeat the urgency of your patient's condition and are still told to divert. You elect to override the physician's order and transport the patient to that hospital. Can you justify disobeying the physician's order?

SUMMARY

- *Ethics* is the discipline relating to right and wrong, moral duty and obligation, moral principles and values, and moral character. *Bioethics* is the science of medical ethics. *Morals* refers to social standards or customs.
- Paramedics must meet a standard established by their level of training and regional practice. They must abide by the law when ethical conflicts occur.
- A paramedic must act in a way that is seen as morally acceptable.
- The rapid approach to resolving ethical issues is a process. It involves reviewing past experiences; deliberation (if possible); and performing the impartiality test, universalizability test, and interpersonal justifiability test to reach an acceptable decision.
- Two concepts of ethical health care are to provide patient benefit and to do no harm.
- All resources must be allocated fairly. This is an accepted bioethical value.
- Advance directives, living wills, and other self-determination documents can help the paramedic make decisions about the appropriateness of resuscitation in the prehospital setting.
- A health care professional is not allowed to reveal details supplied by the patient to others without the patient's consent. This is the principle of confidentiality.
- In some cases, patients refuse lifesaving care. These cases can produce legal and ethical conflicts.
- Other areas likely to raise ethical questions in the prehospital setting include providing care in futile situations, the paramedic's obligation to provide care, patient advocacy, and the paramedic's role as physician extender.

CHAPTER

8 Research Principles and Evidence-Based Practice

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Explain the importance of emergency medical services (EMS) research.
2. Describe the differences between types of EMS research.
3. Outline the 10 steps in performing research that are identified in this chapter.
4. Define evidence-based practice.
5. Describe the criteria for evaluating a research paper.

KEY TERMS

alternative time sampling Sampling to prevent bias by assigning a treatment group based on the day, week, or month in which patients are encountered in a study.

blinding A research specification that dictates that parties are not made aware of the study, treatment, or outcome to be measured.

convenience sampling The process of choosing the individuals who are easiest to reach, or sampling that is easily done; the sample does not represent the entire population.

descriptive statistics Numerical facts or data that do not try to infer anything about a subject that goes beyond the data; can be qualitative or quantitative.

evidence-based practice Practice that is based on current scientific evidence.

hypothesis A statement of the relationship between two or more variables.

inferential statistics A form of statistics that enables the researcher to conclude (infer) whether the relationships seen in a sample are likely to occur in the larger population.

institution review board (IRB) A committee that performs critical oversight functions (scientific, ethical, and regulatory) for research conducted on human subjects.

level of significance The risk of committing a type I error.

mean The arithmetic average of a group being studied.

median A number that is found by first arranging the measurement according to size from smallest to largest, then by choosing the one in the middle; the midpoint of a distribution score.

mode The number that occurs more often than any other number in a set of data.

nuisance variables Variables that can make drawing accurate conclusions from a study difficult.

null hypothesis An exact statement that the results are a chance of variation (the opposite of the hypothesis).

parameter An aspect of a population that is difficult or impossible to measure.

population: A large group of people or places or objects that are the main focus of a scientific query.

qualitative analysis The nonnumerical organization and interpretation of observations.

quantitative analysis Use of the mean, median, and mode to describe the most commonly occurring values in a sample.

random sample A subset of individuals chosen from a larger set; a sample chosen randomly and entirely by chance.

sampling error Error that results from observation of a sample rather than the whole population.

selection bias A distortion of evidence or data that arises from the way the data are collected.

statistically significant A descriptive term used when the observed phenomenon represents a significant departure from what might be expected by chance alone.

statistics A summary of characteristics of numerical facts or data.

systematic sampling A statistical method that involves the selection of a population from an ordered sampling so as to ensure equal probability.

type I error Rejection of the null hypothesis when the hypothesis was true.

type II error Failure to accept the alternative hypothesis when the alternative hypothesis was true.

unblinding A research specification by which all parties are made aware of the study, treatment, and outcome to be measured.

EMS systems are committed to providing effective and efficient health care to acutely ill and injured patients. As the National Highway Traffic Safety Administration has said, EMS agencies face a challenge today. Practices have been based on tradition and expert opinion. They need to be transformed into practices based on guidelines and protocols that have been developed through thoughtful, systematic examination of scientific evidence and data.[1] The paramedic of today must have a basic knowledge of research principles. This knowledge is necessary for conducting research and interpreting published studies. Paramedics also must be willing to help collect research data, which provide important information for the continued development of EMS care.

Courtesy Rick Brady

EMS RESEARCH

Research is a desirable activity for an EMS system. In fact, research is essential to the evolution of emergency medical services. Quality EMS research helps shed light on the intended effects and cost-effectiveness of EMS interventions. The National EMS Research Agenda, published in 2001, states, "Research is essential to ensure that the best possible care is provided in the prehospital setting."[2] This research is based on data and can lead to changes in professional standards, training, equipment, procedures, and improved patient care. In addition, EMS research increases respect for EMS professionals (Box 8-1).

NOTE

For too long, prehospital care has been driven more by what we *think* is right than by what we *know* is right.[1] A system-wide process is needed to ensure that prehospital care is based on current and scientific evidence. This is known as **evidence-based practice**.

CRITICAL THINKING

How do you feel about research?

Types of Research

EMS research has many applications. One application involves gathering data to allow conclusions to be drawn about which procedures, techniques, and equipment are sound. Another application involves gathering data to answer clinically valuable questions and to find results that lead to system improvements. Research is carried out through standard research methods, which include the following:

- *Descriptive (observational) method*: A research design in which events are monitored and analyzed without any attempt to manipulate or alter the outcome.
- *Experimental method*: A research design in which an intervention is introduced and the effects are monitored for an outcome.
- *Prospective method*: A research design in which the specific question, hypothesis, and data collection are defined before the study begins.
- *Retrospective method*: A research design in which the specific question, hypothesis, and data collection are defined after the data already exist.
- *Cross-sectional method*: A research design in which a group of subjects is studied during a specified (usually short) period.

BOX 8-1 Importance of Research in Emergency Medical Services

- Production of outcome-based research
- New procedures, medications, and treatment
- Quality assurance
- Improved patient outcomes
- Professionalism

BASIC PRINCIPLES OF RESEARCH

This chapter describes 10 basic steps for conducting research[3] (Figure 8-1):

1. Prepare a question.
2. Write a hypothesis.
3. Decide what to measure and the best way to measure it.
4. Define the population.
5. Identify study limitations.
6. Seek approval of the study.
7. Obtain informed consent.
8. Gather data after conducting pilot trials.
9. Analyze the data with an awareness of the pitfalls in interpreting the data.

10. Determine what to do with the research product (publish, present, perform follow-up studies).

Prepare a Question

EMS research begins with the posing of a specific problem or question. The research then is carried out using the standard research methods described previously. Examples of problems or questions specifically related to EMS might include the following:

- What factors predict success for paramedic students on the National Registry of EMTs written examination?
- Is the incidence of complications greater with prehospital peripheral vascular access than with hospital peripheral vascular access?
- Does the paramedic uniform influence a patient's satisfaction?
- What is the incidence of violence in an EMS system?
- Does the paramedic's shift length influence the number of medical errors?

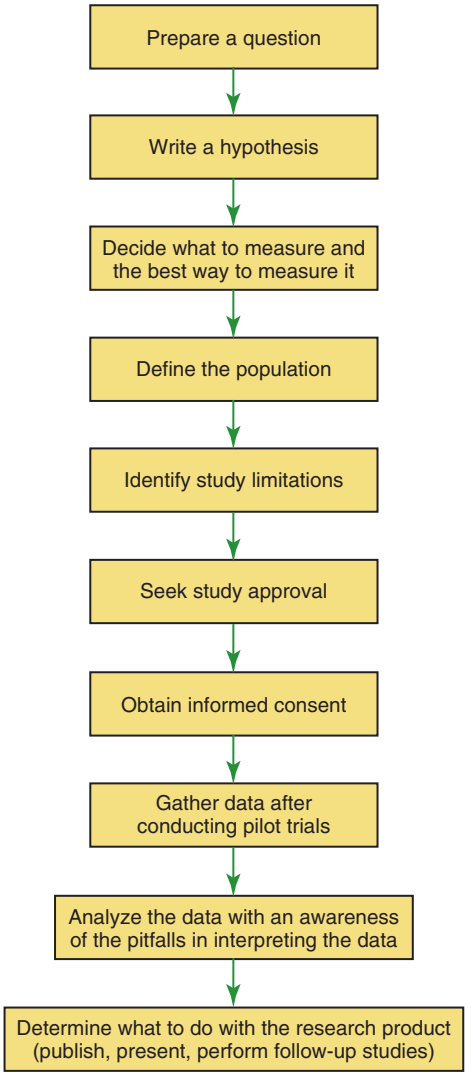

FIGURE 8-1 Ten steps for conducting research.

NOTE

Paramedics should search medical literature for related research. The research should be evaluated for validity and reliability (described later in this text). Reference sources for literature review include peer-reviewed studies, government publications, and literature searches on the Internet.

Write a Hypothesis

After a problem or question to be studied has been identified, a statement to be tested by the study must be defined. This statement is called the **hypothesis.** The hypothesis states the relationship between two or more variables. A *variable* is any factor or entity that can vary in amount or type. For example, the problem might be the ability of one drug to lower a patient's blood pressure more effectively than another drug. A hypothesis for the drug study might be that drug A lowers blood pressure better and with fewer side effects than drug B. A major goal of this step is to decide what to measure and how to measure it.

Define the Population

The next step in the research process is to define the **population** for the study. The population can be any group of people (e.g., all patients with a diastolic blood pressure greater than 100 mm Hg), or any group of places or objects. If the population group is large, the researcher can use a sample (e.g., all patients over 50 years of age who have a diastolic blood pressure greater than 100 mmHg). The researcher should draw the sample randomly. That way, the patients in the study have an equal chance of being assigned to one group (drug A study) or the other (drug B study).

Identify Study Limitations

Drawing a **random sample** prevents **selection bias** (placing the best or worst patients in a study group). The researcher can ensure random sampling with computer software programs, random digits, and even with the flip a coin. Another way to limit bias is with **systematic sampling.** With this method, patients are put into groups in the order in which they are encountered in the prehospital setting. For example, the first patient seen is put into group A, the second into group B, the third into group A, and so on. The researcher also can use **alternative time sampling** to prevent bias by assigning a treatment group based on the day, week, or month in which patients are encountered in the study. **Convenience sampling** is the least preferred method. With this method, patients are assigned to groups when a particular person or crew is working. Even with carefully designed methods, a **sampling error** may occur. Errors result from the fact that even the best sample will not work perfectly to represent the population. This is because of the chance inclusion of one person in the study group rather than the chance inclusion of someone else.

NOTE

A **parameter** is an aspect of a population that is difficult or impossible to measure. For example, determining the exact age (hour of birth) of all patients in a group is nearly impossible. **Nuisance variables** are issues that make drawing accurate conclusions from a study difficult. An example is the use of audible and visual warning devices that can contribute to a rise in a patient's blood pressure. Parameters and nuisance variables are difficult to identify, control, prevent, or eliminate.

In addition to the bias of the researcher, bias can occur on the part of the participants in the study. Bias may be a result of the expectations of the participants. To lessen bias, the researcher can use **blinding** (either single, double, or triple). In a *single blind* method, one party (the patient, the paramedic, or the person gathering the data) is unaware of (blinded to) the treatment at the time it is given. That party also is unaware of the effect to be measured during the study. In a *double blind* study, two parties are blinded. In a *triple blind* study, all parties are blinded. **Unblinding** refers to making all parties aware of the study, treatment, and outcome to be measured.

Seek Approval of the Study

When planning for research involving human subjects, researchers use an **institutional review board (IRB).** IRBs (also known as *independent ethics committees* [IECs] or *ethical review boards* [ERBs]) came into wide use as a result of a mandate from the U.S. Public Health Services in 1966.[4] This mandate required a review by a "committee of institutional associates" for any federally funded research that used human subjects. In the United States, regulations have empowered IRBs to approve research, require modifications in planned research before approval, or disapprove research. These regulations were developed by the U.S. Food and Drug Administration (FDA) and the Department of Health and Human Services (DHHS) (specifically the Office for Human Research Protections [OHRP]). An IRB performs critical oversight functions for research conducted on human subjects. The research is required to be scientific, ethical, and regulatory.

CRITICAL THINKING

Why do you think the development of institution review boards was needed for research?

DID YOU KNOW?

Institution Review Boards

Currently most IRBs involved in EMS research consist of physicians, attorneys, psychologists, ethicists, allied health professionals, and lay members of the community. In fact, many peer-reviewed EMS journals ask for a record that the research was approved by an IRB. Institution review boards seek to reduce the risk of patients unknowingly entering into research that could harm them in any way. In 1981 the U.S. Department of Health and Human Services established the following regulations for research practice (CFR title 45, part 46; revised, 2005).[5] These regulations are observed by most IRBs.

1. Risks to subjects are minimized by using procedures consistent with sound research design that do not unnecessarily expose subjects to risk and, whenever appropriate, by using procedures already being performed on the subjects for diagnostic or treatment purposes.
2. Risks to subjects are reasonable in relation to anticipated benefits, if any, to subjects, and the importance of the knowledge that may reasonably be expected to result. In evaluating risks and benefits, the IRB should consider only risks and benefits that may result from the research (as distinguished from risks and benefits of therapies subjects would receive even if not participating in the research). The IRB should not consider possible long-range effects of applying knowledge gained in the research (e.g., the possible effects of the research on public policy) as among the research risks that fall within the purview of its responsibility.
3. Selection of subjects is equitable. In making this assessment, the IRB should take into account the purposes of the research and the setting in which the research will be conducted, and should be particularly cognizant of the special problems of research involving vulnerable populations, such as children, prisoners, pregnant women, mentally disabled persons, or economically or educationally disadvantaged persons.
4. Informed consent will be sought from each prospective subject or the subject's legally authorized representative in accordance with and to the extent required by *46.116*.
5. Informed consent will be appropriately documented in accordance with and to the extent required by *46.117*.
6. When appropriate, the research plan makes adequate provision for monitoring the data collected to ensure the safety of subjects.
7. When appropriate, adequate provisions are made to protect the privacy of subjects and to maintain the confidentiality of data.
8. When some or all of the subjects are likely to be vulnerable to coercion or undue influence (e.g., children, prisoners, pregnant women, mentally disabled persons, or economically or educationally disadvantaged persons), additional safeguards are included in the study to protect the rights and welfare of these subjects.

Obtain Informed Consent

With informed consent, the subject voluntarily agrees to take part in the research project. The subject has decisional capacity and understands what is being presented. With respect to EMS research and the problems associated with obtaining informed consent in emergency situations, alternatives to informed consent have been developed, including the following[3]:

- *Consent at a distance.* The base station physician administers informed consent to the subject by radio or telephone.

- *Consent by proxy*. The paramedic administers informed consent to the subject.
- *Stepped consent*. The paramedic provides the subject with a brief overview of the experimental therapy. Full informed consent is obtained at the hospital.
- *Cohort consent*. Permission is obtained to enter into the study at some future time (e.g., during an asthma exacerbation or sickle cell crisis).
- *Deferred consent*. This type of consent is used during resuscitation; the subject's condition is stabilized and the person receives experimental therapy without permission, after which the family is approached for traditional informed consent.
- *Surrogate consent*. Lay people are presented with the experimental protocol and are asked to state whether they believe the treatment is appropriate.
- *Consent jury*. A lay panel determines certain aspects of the experimental protocol, particularly potential risks and complications that must be presented during a request for consent.

NOTE

A waiver of informed consent may be permitted in some emergency research. To be granted this waiver, the researchers must prove that they have informed the community about the research. The research team must also solicit feedback from the community about the proposed research. This is known as *community consultation and public disclosure.*

SHOW ME THE EVIDENCE

Nelson and colleagues collected a cross-sectional, standardized survey conducted by two sets of random-digit telephone surveys, paper surveys at community meetings, and Web-based surveys. Their goal was to comply with federal law that allows research to be conducted using very strict criteria without having prior consent of the patient. The surveys were done to fulfill the law's requirement for community consultation and public disclosure. The authors found that community meetings were poorly attended and that phone surveys were effective for gauging public opinion. However, they recommended targeted surveys to reach special populations.

Nelson M et al: Community consultation methods in a study using exception to informed consent, *Prehosp Emerg Care* 12:417-425, 2008.

Gather and Analyze Data

Data from the research study should be gathered and analyzed using statistical methods. The term **statistics** refers to numerical facts or data. These facts or data are classified and put into a chart to present key details about a subject. Statistics can be descriptive or inferential.

DESCRIPTIVE STATISTICS

Descriptive statistics does not try to conclude (infer) anything about a subject that goes beyond the data. This type of statistics provides a description of the sample of objects or people being studied. It does not infer anything from the data; it simply reports it. Descriptive statistics can be qualitative or quantitative.

Qualitative analysis is nonnumerical; it is the organization and interpretation of observations. The sample size in qualitative research usually is very small. Qualitative analysis is used to find key underlying dimensions and patterns in a group. For example, it would show the age and gender of a sample. Qualitative analysis uses text and few numbers to describe the research findings. The conclusions from qualitative research involve themes, trends, or theories derived from interviews, discussion, or observation of the study population.

Quantitative analysis in descriptive statistics uses the mean, median, and mode to describe the most commonly occurring values in a sample. The **mean** is the arithmetic average of the group (e.g., the average age of the people in the sample). The **median** is found first by arranging the measurement according to size from smallest to largest and then by choosing the one in the middle (or the mean of the two that are nearest to the middle). The median sometimes is referred to as the *50th percentile*. The median frequently is used to divide a sample into two halves. The **mode** is the number that occurs more often than any other number in a set of data. The following is an example of quantitative analysis:

Your sample has 13 participants. Their ages are 53, 53, 53, 54, 55, 55, 56, 57, 59, 60, 64, 71, and 79. The *mean* (average) age of the group is 59.15 years; the *median* (middle) age is 56; and the *mode* age is 53.

INFERENTIAL STATISTICS

Inferential statistics is used to infer whether the relationships seen in a sample are likely to occur in the larger population. The researcher can use these statistics to decide whether the results of the study support or contradict the initial hypothesis. To do this, one must assume the opposite of what one may want to prove. This is done by stating a **null hypothesis.** A null hypothesis is a default position, such as that a specific treatment has no effect or that the results are a chance of variation (the opposite of what you expect to prove). This is done in court, where the accused is assumed to be innocent until proved guilty beyond a reasonable doubt. The assumption that the accused is not guilty is a null hypothesis. If the assumption cannot be rejected, the accused goes free. However, this does not always mean that the accused actually is innocent. A *research hypothesis* is the opposite of the null hypothesis (e.g., the accused is guilty until proved innocent).

NOTE

The sureness with which a null hypothesis can be rejected is called *confidence*. The *confidence interval* is the range where a researcher "expects" something to be true, leaving open the possibility of being wrong. The *degree of confidence* measures the probability of that expectation to be true. It is linked with the width of the confidence interval and often is reported in research journals.

It is easy to be very confident that something will be within a very wide range, and vice versa. For example, one can be fairly confident that a classroom of children would prefer soda over water. The degree of confidence and the width of the confidence interval for this study would be quite large. However, if the question to be studied is, "Do children prefer Coke, Pepsi, or Mountain Dew?" the degree of confidence and the width of the confidence interval become narrow.

When a statistical test reveals that the probability is rare that a set of results is attributable to chance alone, this result is called **statistically significant.** *Statistically significant* means that the observed phenomenon represents a significant departure from what might be expected by chance alone.

The **level of significance** is the probability of a **type I error** that an investigator is willing to risk in rejecting a null hypothesis. Generally, the *level of significance* refers to the probability of the event occurring as a result of chance. The level of significance is the acceptable risk of sampling errors and is established through mathematical equations. The level of significance is usually 0.05 (1 chance in 200) or 0.01 (1 chance in 100) that the difference between two groups is larger than expected as a result of chance alone (too large to be reasonably attributed to chance). If the level of significance is lowered from 0.05 to 0.01, the probability of rejecting a true hypothesis is decreased and the probability of accepting a false hypothesis is increased. A **type II error** occurs when an investigator fails to accept the alternative hypothesis when in fact the alternative hypothesis was true. In other words, the null hypothesis was accepted when it was not true. Researchers must set their level of significance before they begin their research.

NOTE

In statistics, rejection of the null hypothesis when it is true (a false alarm) is referred to as a *type I error*. Acceptance of the null hypothesis when it is false (failure to detect a real phenomenon) is a *type II error*. A type II error occurs when the phenomenon is *too* small to see.

Determine What to Do with the Results

The final step in EMS research is to determine what to do with the results of the study. Several options are available, including publishing the results, presenting the results, and performing follow-up studies.

PUBLISHING THE RESULTS

The findings from research may be published in a professional journal for peer evaluation. (Sometimes just an abstract, or summary, of the research is published. Published abstracts have not gone through the same rigorous peer-review process as a full article.) The format for writing a manuscript for scientific literature has five basic sections:

1. The *introduction* provides a brief historical background of the research. It also relates any previously published research. The introduction provides both a rationale for the study and the research hypothesis.
2. The *methods section* describes how the experiment was done so that it can be replicated by others. This section should define the inclusion or exclusion criteria for the study (how patients were chosen). It also should contain the statistical methods used to analyze the data.
3. The *results section* provides answers to study questions and data (e.g., tables and figures). This information supports the research findings.
4. The *discussion section* lets the author interpret the research findings. Limitations of the project usually are also given here. This section frequently offers suggestions for improving the study through follow-up research.
5. The *conclusion* provides a succinct summary of the four preceding sections (Box 8-2).

PRESENTING THE RESULTS AND FOLLOW-UP STUDIES

Presenting the results of a study can help put research into practice. Presentations can be made to peers, professional organizations, and higher education institutions. Clinical studies can lead to improvements in patient outcomes. Funding may be available for follow-up studies. These studies may be done through collaborative efforts with public agencies, corporations, and foundations. Studies also may be funded and supported through state and federal government programs that support research

BOX 8-2 Fifteen Steps for Evaluating and Interpreting Research

1. Was the research peer reviewed?
2. What was the research hypothesis?
3. Was the study approved by an institutional review board and conducted ethically?
4. What was the population studied?
5. What were the inclusion and exclusion criteria for the study?
6. What method was used to draw a sample of patients?
7. How many patient groups participated?
8. How were patients assigned to groups?
9. What type of data was gathered?
10. Does the study appear to have had a sufficient number of patients enrolled?
11. Does the study fail to account for any potential confounding variables?
12. Were the data properly analyzed?
13. Is the author's conclusion logical and based on the data?
14. Could the results apply in local EMS systems?
15. Are the patients in the study similar to those seen in the local EMS system?

consortia. (A *consortium* is a group of individuals and/or organizations that pool resources and information to achieve a common goal.) An example of organizations that may be members of a local research consortium is area hospitals and EMS agencies that collect and share data.

EVIDENCE-BASED PRACTICE

Traditional medical practice has been based on medical knowledge, intuition, and judgment. With the emphasis moving toward evidence-based practice, many medical specialties have developed evidence-based guidelines for specific conditions, such as traumatic brain injury, spinal injury, and ST-segment elevation myocardial infarction. (These conditions are addressed by subject matter later in the text.)

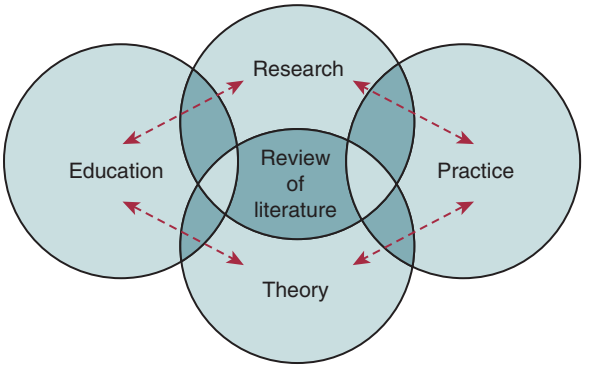

FIGURE 8-2 Relationship of the review of the literature to theory, research, education, and practice. (LoBiondo-Wood G, Haber J: *Nursing research: methods and critical appraisal for evidence-based practice,* ed 7, St Louis, 2010, Mosby.)

NOTE

The National Guideline Clearinghouse (NGC) is a public resource for evidence-based, clinical practice guidelines and related documents. The mission of the NGC is to provide physicians and other health professionals with an accessible means of obtaining objective, detailed information on clinical practice guidelines. Another goal of the NGC is to disseminate practice guidelines for implementation and use.[6]

High-quality patient care should focus on procedures that have been proven useful in improving patient outcomes.[7] Paramedics should participate in EMS research, data collection, and the sharing of information. These efforts aid in the design of a system-wide process for prehospital care that reflects the current state of scientific evidence (Figure 8-2).

Reviewing Research

When reviewing research articles, paramedics should read the article critically to determine whether the findings are relevant to their practice. They should look carefully at the following components[8]:

1. *Population.* Is the sample adequate and is it similar to your practice? For example, a study that evaluates response times without lights and sirens conducted in a rural setting may not be relevant to an urban EMS system. Another example is a study conducted in an area that has a significantly different ethnic makeup than your practice area. This could influence results if the study subject involves disease processes that are more prevalent in some ethnic communities.
2. *Inclusion and exclusion criteria.* A study of patients with chest pain that did not include patients older than age 65, for example, would eliminate a key group at risk for heart disease and death.
3. *Data collection.* Is there anything that could have influenced the data collection? If the study used the experimental method, how were the groups randomized? Was the method clearly described? Could the method have varied based on the person delivering care? Were the conditions in the control group and the experimental group the same?
4. *Results.* Are the numbers presented clearly? When percentages are presented, are the underlying numbers reported? If a statistically significant difference was seen in the outcome, is it also clinically significant?
5. *Discussion and conclusion.* Is the conclusion consistent with the results reported? Did the authors properly report correlations and relationships, rather than predictions? Did they link the research to relevant literature? Were the limitations of the study pointed out clearly? Did the researchers make specific suggestions for future research? Did you identify any major flaws in the conclusion?
6. *How does this research relate to your practice?* Does the research suggest an area of improvement for your system? Does it suggest an area that should be monitored in your quality improvement program? Is there a reason to seek out more literature on the same subject to propose a change in your system?

SUMMARY

- The paramedic must be familiar with research principles. This knowledge is needed to conduct research, collect research data, and interpret published studies.
- Research is essential to improving patient care.
- Two main types of research are the descriptive method and the experimental method. Data are collected by various methods. These methods may be prospective, retrospective, or cross-sectional.
- The 10 steps of EMS research are (1) prepare a question; (2) write a hypothesis; (3) decide what to measure and how to measure it; (4) define the population; (5) identify the study limitations; (6) seek IRB approval; (7) obtain informed consent; (8) gather data after conducting pilot trials; (9) analyze the data; and (10) present the data.
- Descriptive statistics does not try to infer anything about a subject that goes beyond the data.
- Qualitative analysis provides a nonnumerical description of the population. Quantitative data analysis evaluates the data using numbers.
- Inferential statistics infers whether the relationships seen in a sample are likely to occur in the larger population. In this type of study, researchers develop a null hypothesis.
- EMS care should be evidence-based; that is, interventions and procedures should be proven to benefit the patient.
- Paramedics should read research articles critically to determine whether the article is relevant to their practice.

Anatomy and Physiology

Chapter 9: Medical Terminology
Chapter 10: Review of Human Systems
Chapter 11: General Principles of Pathophysiology
Chapter 12: Life Span Development

CHAPTER

9 Medical Terminology

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Explain the use of medical terms to describe organs and processes.
2. Explain the role of a prefix, root word, combining vowel, and suffix in a medial term.
3. Interpret selected examples of medical prefixes, root words, combining vowels, and suffixes.
4. Distinguish between singular and plural forms of medical terms.
5. Use accepted medical abbreviations appropriately.
6. Differentiate between similar medical terms and abbreviations

KEY TERMS

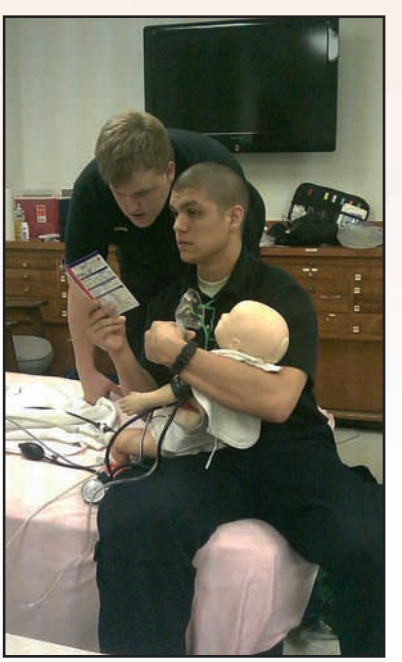
combining vowels Vowels often used between root words and suffixes or between two or more root words.

prefix One or more root syllables at the beginning of a word; a prefix often describes location or intensity.

root words Medical words that may be combined to describe a particular structure or condition.

suffix A word part that appears at the end of a medical word; the suffix often describes a patient's condition or diagnosis.

A necessary skill for working in the health care profession is the ability to speak and understand the language of medicine. This skill is required for conveying patient information to other members of the heath care team. In addition, medical terminology is universally understood. It provides a clear and concise way to document patient care activities.



(Courtesy Kim McKenna, St. Charles, Mo.)

THE LANGUAGE OF MEDICINE

The language of medicine offers intriguing challenges both to medical historians and to linguists. The oldest written sources of Western medicine are the Hippocratic writings from the fourth and fifth centuries BC. This was the beginning of the Greek era of the language of medicine. This era lasted even after the Roman conquest. During the Renaissance (fourteenth to seventeenth centuries), the Greek language was not widely understood. Over time, Greek words

were translated into Latin. As a result, most medical terms today are derived from Greek, and many have Latin roots. Medical terms that describe a disease are usually of Greek origin. Medical terms used to describe anatomy are usually of Latin origin.[1]

NOTE

Most major medical journals are written in English. In addition, English has become the language of choice at international medical conferences. Newer medical terms are being coined from ordinary English words. Examples include *bypass*, *shunt*, *pacemaker*, and *screening*. Non-English-speaking countries often translate these terms into their own language. These countries also accept and use English acronyms, such as AIDS (acquired immune deficiency syndrome) and CPR (cardiopulmonary resuscitation).

WORD PARTS OF MEDICAL TERMINOLOGY

Medical terms (Table 9-1) are used as descriptives for:

- Body structures and systems
- Anatomical regions and locations
- Diseases and other health problems
- Medical and surgical procedures
- Diagnostic tests
- Medical instruments

Most medical terms can be broken down into one or more word parts. For the sake of simplicity, these word parts are known as *prefixes, suffixes, root words,* and some *linking* or *combining vowels*. A knowledge of the basic word parts can help paramedics understand medical terminology and use it correctly (Figure 9-1).

Prefixes

A **prefix** is one or more root syllables at the beginning of a word. In medical terminology, a prefix often describes location and intensity. For example, the word *abnormal* begins with the prefix *ab*, which means "away from." This is followed by *normal*, which means "within a balance." Therefore, *abnormal* describes something that is not within balance. Other common prefixes are listed in Table 9-2.

Suffixes

A **suffix** appears at the end of a medical word. In medical terminology, a suffix often describes a patient's condition or diagnosis. For example, *bronchitis* begins with the root word *bronchi* (a respiratory structure). The root word, *bronchi*, is followed by the suffix *itis*, which means "inflammation." Therefore, *bronchitis* describes inflammation of the bronchi. Other common suffixes are listed in Table 9-3.

Root Words

Root words are medical words that may be combined to describe a particular structure or condition. They usually are derived from Latin or Greek nouns, verbs, or adjectives. For example, *cardiopulmonary* begins with the root word *cardio*, which means "heart"; the next root word is *pulmonary*, which means "lungs." Therefore, *cardiopulmonary* refers to the cardiac and respiratory systems. Other common root words are listed in Table 9-4.

TABLE 9-1 Examples of Medical Terms

Body Structures and Systems

Aden/o: Gland
Cardi/o: Heart
Cyt/o: Cell
Hist/o: Tissue
Neur/o: Nerve
Viscer/o: Internal organs

Anatomical Regions and Locations

Anteroposterior: Pertaining to the front and to the back
Bilateral: Pertaining to two sides
Caudal: Pertaining to the tail
Cephalic: Pertaining to the head
Dorsal: Pertaining to the back

Diseases and Other Health Problems

Aphagia: Without swallowing (inability to swallow)
Carcinoma: Cancerous tumor (malignant)
Dyspnea: Difficulty breathing
Neoplasm: New growth (of abnormal tissue or tumor)
Sepsis: Systemic infection

Medical and Surgical Procedures

Appendectomy: Surgical removal of the appendix
Endoscopy: Visual examination of a hollow organ or body cavity
Hemodialysis: Removal of impurities from the blood
Laryngoscopy: Visual examination of the larynx
Nephrectomy: Surgical removal of a kidney

Medical Instruments

Capnometer: Used to measure carbon dioxide
Ophthalmoscope: Used to evaluate the eye
Otoscope: Used to evaluate the inner ear
Oximeter: Used to measure oxygen
Sphygmomanometer: Used to measure blood pressure

Diagnostic Tests

Arterial blood gases (ABGs): A test performed on arterial blood to determine levels of oxygen, carbon dioxide, and other gases
Computed tomography (CT) scan: Computerized imaging of body organs in sectional slices
Magnetic resonance imaging (MRI): An imaging technique in which magnetic and radio waves are used to produce images of organs and tissues in all three planes of the body
Purified protein derivative (PPD) skin test: A test performed on individuals who have been recently exposed to tuberculosis
Ultrasonography: An imaging technique in which scans are obtained through the use of high-frequency sound waves

NOTE

A medical term must have at least one root word, but it does not have to have either a prefix or a suffix. For example, the term *sternocleidomastoid* can be divided into three root words: *stern, cleid,* and *mastoid*. The sternocleidomastoid is a muscle that has attachments at the sternum, the clavicle, and the mastoid.

Combining Vowels

Combining vowels are also known as *linking vowels*. Combining vowels make medical terms easier to pronounce. The vowel most often used is *o*. An example of the use of a combining vowel is shown in the preceding box for the term *sternocleidomastoid: stern*—**o**—*cleid*—**o**—*mastoid*. Other vowels, such as *i* and *a,* are also used. Combining vowels often are used between root words and suffixes, as well as between two or more root words. They are not used between prefixes and root words. Table 9-5 presents guidelines for the use of combining vowels.

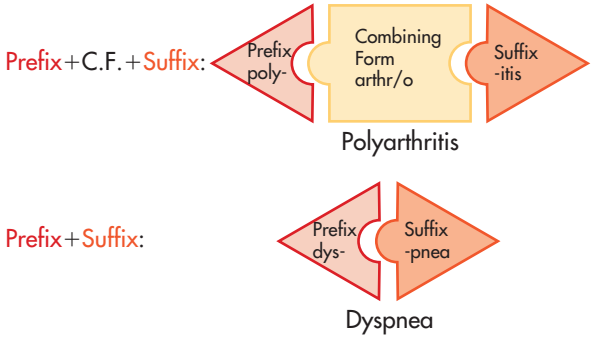


FIGURE 9-1 The relationship of prefixes, suffixes, and combining words. (Leonard PC: *Quick and easy medical terminology,* ed 6, St Louis, 2011, Saunders.)

NOTE

An easy way to learn medical terminology is to use an organized approach to examine the word parts of a medical term. One way to analyze a medical term is to begin with the suffix. Then look at the prefix. The remaining part is the root word. Put the three parts of the term together into a definition of the word.

Example: Pericardial

The suffix is *-al* (pertaining to); the prefix is *peri-* (around); the root word is *cardio* (heart). The definition, then, is: Pertaining to around the heart.

PLURAL FORMS OF MEDICAL TERMS

As do words in any language, medical terms need both a singular form and a plural form. Because most medical terms are Greek or Latin in origin, some unusual rules must be followed to change a singular word into its plural form. These rules are presented in Table 9-6.

TABLE 9-2 Common Prefixes

Prefix	Meaning	Example
a-, an-	without, lack of	apnea (without breath) anemia (lack of blood)
ad-	to, toward	adhesion (something stuck to or remaining close to)
angio-	vessel	angiogram (the study of vessels)
ante-	before, forward	antenatal (occurring or formed before birth)
anti-	against, opposed to	antipyretic (against fever)
arter-	artery	arteriogram (study of arteries)
arthro-	pertaining to a joint	arthroscopy (inspection of a joint)
bi-	two	bilateral (both sides)
bio-	life	biology (the study of life)
brady-	slow	bradycardia (slow heart rate)
cardi-	pertaining to the heart	cardiography (recording the movements of the heart)
cerebr-	brain	cerebral (pertaining to the brain)
cerv-	neck	cervical (pertaining to the neck)
chole-	pertaining to bile	cholelithiasis (stones in the gallbladder)
contra-	against, opposite	contrastimulant (against stimulating)
cost-	pertaining to a rib	costal margin (margin of the lower limit of the ribs)
cyst-	pertaining to the bladder or any fluid-containing sac	cystitis (inflammation of the urinary bladder)
cyt-	cell	cytology (the study of cells)
di-	twice, double	diplopia (double vision)
dys-	with difficulty	dyspnea (difficulty breathing)
ecto-	out from	ectopic (out of place)

TABLE 9-3 Common Suffixes

Suffix	Meaning	Example
-algia	pertaining to pain	neuralgia (pain along a nerve)
-centesis	puncturing	thoracentesis (puncturing into a pleural space)
-cyte	cell	leukocyte (white cell)
-ectomy	a cutting out	tonsillectomy (surgical removal of the tonsils)
-emia	blood	anemia (a decrease in blood hemoglobin)
-esthesia	sensation	anesthesia (without sensation)
-genic	causing	carcinogenic (cancer causing)
-ology	science of	psychology (the science or study of behavior)
-ostomy	creation of an opening	gastrostomy (artificial opening into the stomach)
-osis	condition	psychosis (condition of the mind)
-paresis	weakness	hemiparesis (one-sided weakness)
-phagia	eating	polyphagia (excessive eating)
-pnea	breathing	dyspnea (difficulty breathing)
-pathy	disease	neuropathy (disease of the peripheral nerves)
-phasia	speech	aphasia (loss of the power of speech)
-plasty	repair of, tying of	angioplasty (repair of damaged vessels)
-rhythmia	rhythm	dysrhythmia (variation from a normal rhythm)
-rrhagia	bursting forth	hemorrhage (flowing of blood)
-rrhea	flowing	pyorrhea (discharge of pus)
-scopy	examination by inspection	laparoscopy (examination of the abdominal cavity with a laparoscope)
-uria	pertaining to urine	polyuria (excessive secretion of urine)

TABLE 9-4 Common Root Words

Root Word	Meaning	Root Word	Meaning
adeno-	gland	mal-	bad
arter-	artery	meningo-	meninges
arthro-	joint	myo-	muscle
asthenia-	weakness	nephro-	kidney
bio-	life	neuro-	nerve
bucc-	cheek	noct-	night
burs-	pouch or sac	oculo-	eye
carc-	cancer	orchi-	testicle
cardio-	heart	osteo-	bone
caut-	to burn	oto-	ear
cephalo-	head	ov-	egg
cerv-	neck	pariet-	wall
chole-	bile	phago-	to eat
chondro-	cartilage	pharyngo-	throat
cysto-	bladder	phlebo-	vein
cyto-	cell	photo-	light
dermo-	skin	pneumo-	air
edem-	swelling	procto-	rectum
entero-	intestine	pseud-	false
eryth-	red	psych-	mind
eti-	cause	pyo-	pus
febr-	fever	rhino-	nose
flex-	to bend	sclero-	hardness
gastro-	stomach	sept-	wall
glyco-	sugar	somat-	body
gyn-	female	stern-	chest
hemo-	blood	tact-	to touch
hepato-	liver	thoraco-	chest
hydra-	water	uro-	urinary
iod-	distinct	varic-	dilated vein
leuko-	white	vaso-	vessel

TABLE 9-5 Guidelines for Using Combining Vowels

1. When a word root and a suffix are connected, a **combining vowel** *IS USED* **if the suffix** *DOES NOT BEGIN* **with a vowel.**
   arthr/**o**/pathy
2. When a word root and a suffix are connected, a **combining vowel** *USUALLY IS NOT USED* **if the suffix** *BEGINS* **with a vowel.**
   hepat/ic
3. When two word roots are connected, a **combining vowel** *USUALLY IS USED* **even if vowels are present at the junctions.**
   oste/**o**/arthr/it/is
4. When a prefix and a word root are connected, a **combining vowel** *IS NOT USED*.
   sub/hepat/ic

MEDICAL ABBREVIATIONS, ACRONYMS, AND SYMBOLS

Many EMS systems develop agency-approved medical abbreviations. Medical abbreviations, including acronyms and symbols, promote efficient communication and documentation. Communication and documentation of medical information require thoroughness, precision, and accuracy. Medical abbreviations, acronyms, and symbols are a form of medical shorthand. They are universally understood by other members of the heath care team. Some of the more

TABLE 9-6 Guidelines for Pluralizing Medical Terms

Guideline	Singular Form	Plural Form
1. If the term ends in "a", the plural is formed by adding an "e".	bursa	bursae
2. If the term ends in "ex" or "ix", the plural is formed by changing ex/ix to "ices".	vertebra	vertebrae
	appendix	appendices
	cervix	cervices
3. If the term ends in "is", the plural is formed by changing the is to "es".	diagnosis	diagnoses
	neurosis	neuroses
	metastasis	metastases
4. If the term ends in "itis", the plural is formed by dropping the s and adding "des".	arthritis	arthritides
	meningitis	meningitides
5. If the term ends in "nx" the plural is formed by changing the x to "g" and adding "es".	phalanx	phalanges
	larynx	larynges
6. If the term ends in "on", the plural is formed by dropping the on and adding "a".	criterion	criteria
	ganglion	ganglia
7. If the term ends in "um", the plural is formed by changing um to "a".	diverticulum	diverticula
	ovum	ova
8. If the term ends in "us", the plural is formed by changing us to "i".	alveolus	alveoli
	bronchus	bronchi
	malleolus	malleoli

From National Safety Councils of Canada: *Introduction to medical terminology,* 2005.

common medical abbreviations, acronyms, and symbols used in EMS systems can be found in Box 9-1.

NOTE

Many medical abbreviations and acronyms may have common, multiple meanings. For example, the acronym ***PE*** may be used for *physical examination, pulmonary edema,* or *pulmonary embolism*. Therefore, it is important for every EMS agency or medical direction system to have an approved list of medical abbreviations and acronyms. This helps ensure precision in documentation. It also facilitates patient assessments and patient histories. In addition, approved lists may provide for medical-legal protection if cases are reviewed for litigation.

Do Not Use List

In May, 2005, The Joint Commission (formerly known as the Joint Commission on Accreditation of Healthcare Organizations, or JCAHO) affirmed its "Do Not Use" list of abbreviations (originally created in 2004).[2] The list, which is updated annually, is designed to eliminate the use of abbreviations, acronyms, symbols, and drug dose designations that could be confusing or dangerous and that might result in errors. Many EMS agencies and health care facilities use this list as part of their documentation protocol (Table 9-7).

SHOW ME THE EVIDENCE

Brunetti and colleagues found that nearly 5% of the errors reported to Medmarx, a national database for medication errors, were related to abbreviation use. Many of the abbreviations involved in the errors were on the official "Do Not Use" list of abbreviations established by The Joint Commission (formerly known as the Joint Commission on Accreditation of Healthcare Organizations).

From Brunetti L, Santell JP, Hicks RW: The impact of abbreviations on patient safety, *The Joint Commission Journal on Quality and Patient Safety* 33:576-583, 2007.

PRONUNCIATION OF MEDICAL TERMS

Correct spelling and pronunciation of medical terms are necessary for good communication. These skills are expected of health care professionals. A good way to learn (and remember) the spelling and pronunciation of medical terms is first to consider the way the terms are built. This is done by analyzing the root words, prefixes, and suffixes described earlier in the chapter. Understanding root words and memorizing these terms and their correct spelling, can help paramedics build a medical vocabulary.

The pronunciation of medical terms often varies, because no "rigid rules" exist. In addition, medical terms often are pronounced somewhat differently even among medical professionals. Some medical terms can be acceptably pronounced in more than one way (Table 9-8). A common

BOX 9-1 Common Medical Abbreviations Used by EMS Systems*

°C	degrees Centigrade
°F	degrees Fahrenheit
ABG	arterial blood gas
Ac	before meals
ACS	acute coronary syndrome
ad lib	freely as desired
ADHD	attention deficit/hyperactivity disorder
ADL	activities of daily living
AED	automated external defibrillator
Afib	atrial fibrillation
AICD	automatic implanted cardioverter defibrillator
AIDS	acquired immunodeficiency syndrome
ALS	amyotrophic lateral sclerosis
AM	morning
A.M.A.	against medical advice
AMI	acute myocardial infarction
amp	ampule
ARC	AIDS-related complex
ARDS	acute respiratory distress syndrome
AS	aortic stenosis
ASD	atrial septal defect
BE	barium enema
bid	two times a day
BiPAP	Bilevel positive airway pressure
BLS	basic life support
BM, bm	bowel movement
BNP	brain natriuretic peptide
BMR	basal metabolic rate
BP	blood pressure
BPH	benign prostatic hypertrophy
BPM	beats per minute
BSA	body surface area
BUN	blood urea nitrogen
BVM	bag valve mask
	with
c/o	complains of
Ca	calcium, cancer, carcinoma
CAD	coronary artery disease
cap	capsule
CAT	computed axial tomography
cath	catheter, catheterize
CBC	complete blood count
CBR	complete bed rest
CC	chief complaint
CCU	coronary care unit, critical care unit
CDC	Centers for Disease Control and Prevention
CHF	congestive heart failure
CHO	carbohydrate
Cl	chlorine
cm	centimeter
cm^3	cubic centimeter
CNS	central nervous system
CO	carbon monoxide
CO_2	carbon dioxide
COPD	chronic obstructive pulmonary disease
CPAP	continuous positive airway pressure
CPK	creatine phosphokinase
CPR	cardiopulmonary resuscitation
CSF	cerebrospinal fluid
CT	computed tomography
CVA	cerebrovascular accident, costovertebral angle
CVP	central venous pressure
D&C	dilation and curettage
D_5W	5% dextrose in water
DB	diabetes
dc	discontinue
DIC	disseminated intravascular coagulation
diff	differential blood count
dil	dilute
DJD	degenerative joint disease
dL	deciliter
DM	diastolic murmur
DNR/DNAR	do not resuscitate
DOE	dyspnea on exertion
DVT	deep vein thrombosis
dx, DX	diagnosis
EBV	Epstein-Barr virus
ECF	extracellular fluid
ECG	electrocardiogram
ECT	electroconvulsive therapy
ED	emergency department
EDC	estimated date of confinement
EDD	estimated date of delivery
EEG	electroencephalogram
EKG	electrocardiogram
elix	elixir
EMG	electromyogram
ENG	electronystagmography
ER	emergency room
ESR	erythrocyte sedimentation rate
ESRD	end-stage renal disease
EST	electroshock therapy
$etCO_2$	end-tidal carbon dioxide
ETOH	ethyl alcohol
Fe	iron
FEV	forced expiratory volume
FHR	fetal heart rate
FRC	functional residual capacity
FUO	fever of unknown origin
Fx, fx	fracture, fractional urine test
g, gm, Gm	gram
GCS	Glasgow Coma Scale
GERD	gastroesophageal reflux disease
GI	gastrointestinal
Grava I, II, III, etc.	pregnancy one, two, three, etc.
gt, gtt	drop, drops
GTT	glucose tolerance test
GU	genitourinary
GYN, Gyn	gynecological
H_2O	water
H^+	hydrogen ion

Continued

BOX 9-1 Common Medical Abbreviations Used by EMS Systems—cont'd

h/o	history of
H&P	history and physical examination
HAV	hepatitis A virus
Hb	hemoglobin
HBV	hepatitis B virus
Hct, HCT	hematocrit
Hg	mercury
Hgb	hemoglobin
HIV	human immunodeficiency (AIDS) virus
HSV	herpes simplex virus
HTN	hypertension
IBD	irritable bowel disease
I&O	intake and output
IC	inspiratory capacity
ICP	intracranial pressure
ICU	intensive care unit
IDDM	insulin-dependent diabetes mellitus
Ig	immunoglobulin
IgA, etc.	immunoglobulin A, etc.
IM	Intramuscular
INR	International normalized ratio
IO	intraosseous
IPPB	intermittent positive-pressure breathing
ITD	impedance threshold device
IV	intravenous
IVP	intravenous push; intravenous pyelogram
IVPB	intravenous piggy back
J	joules
K	potassium
kg	kilogram
KUB	kidney, ureters, and bladder (radiograph)
KVO	keep vein open
L	liter
L&A	light and accommodation
LBBB	left bundle branch block
LE	lupus erythematosus
LLL	left lower lobe
LLQ	left lower quadrant
LMP	last menstrual period
LNMP	last normal menstrual period
LP	lumbar puncture
LR	lactated Ringer's solution
LUL	left upper lobe
LUQ	left upper quadrant
LV	left ventricle
LVAD	left ventricular assist device
LVH	left ventricular hypertrophy
M	meter
MAP	mean arterial pressure
min	minim
max	maximum
MAP	mean arterial pressure
mcg, mg	microgram
MCH	mean corpuscular hemoglobin
MCHC	mean corpuscular hemoglobin concentration
MCV	mean cell volume, mean corpuscular volume
mg	milligram
Mg	magnesium
MG	myasthenia gravis
MI	myocardial infarction
min	minute(s)
MICU	medical intensive care unit
mL	milliliter
mm	millimeter
mm^3	cubic millimeter
mm Hg	millimeters of mercury
MOI	mechanism of injury
MRI	magnetic resonance imaging
MS	multiple sclerosis
mV	millivolt
N	nitrogen
Na	sodium
NG	nasogastric
NICU	neonatal intensive care unit
NIPPV	noninvasive positive pressure ventilation
NOI	nature of illness
NPA	nasopharyngeal airway
NPO	nothing by mouth
NS	normal saline
O_2	oxygen
OCD	obsessive compulsive disorder
OD	overdose
OG	orogastric
OPA	oropharyngeal airway
ORIF	open reduction and internal fixation
OT	occupational therapy
OTC	over-the-counter
oz	ounce
$Paco_2$	partial pressure of carbon dioxide (arterial blood)
Pao_2	partial pressure of oxygen (arterial blood)
para I, ... II, etc	unipara, bipara, etc.
PAT	paroxysmal atrial tachycardia
pc	after meals
PCI	percutaneous coronary intervention
Pco_2	partial pressure of carbon dioxide
PCP	pulmonary capillary pressure, phencyclidine
PCV	packed cell volume
PCWP	pulmonary capillary wedge pressure
PE	pulmonary embolism, physical examination
PEEP	positive-end expiratory pressure
PEF	peak expiratory flow
per	through, by way of
PERRLA	pupils equal, round, and reactive to light and accommodation
PET	positron emission tomography
PG	prostaglandin
pH	hydrogen ion concentration (acidity and alkalinity)

BOX 9-1 Common Medical Abbreviations Used by EMS Systems—cont'd

PID	pelvic inflammatory disease
PIH	pregnancy-induced hypertension
PKU	phenylketonuria
PM	postmortem
pm	evening
PMS	premenstrual syndrome
PND	paroxysmal nocturnal dyspnea, postnasal drip
Po_2	partial pressure of oxygen
PO, po	orally
PPD	purified protein derivative
ppm	parts per million
prn	when required, as often as necessary
PSVT	paroxysmal supraventricular tachycardia
PT	physical therapy; prothrombin time
PTSD	post-traumatic stress disorder
PTT	partial thromboplastin time
PVC	premature ventricular complex
q	every
q2h	every 2 hours
q3h	every 3 hours
q4h	every 4 hours
qh	every hour
QID	four times a day
qn	every night
qod	every other day
qns	quantity not sufficient
R/O	rule out
RA	rheumatoid arthritis
RBBB	right bundle branch block
RDS	respiratory distress syndrome
Rh+	positive Rh factor
Rh-	negative Rh factor
RHD	rheumatic heart disease
RLL	right lower lobe
RLQ	right lower quadrant
RML	right middle lobe
ROM	range of motion
ROS	review of systems
ROSC	return of spontaneous circulation
RSI	rapid sequence intubation
RSV	respiratory syncytial virus
RUL	right upper lobe
RUQ	right upper quadrant
Rx	take; treatment
	without
SB	sternal border
sec	second(s)
sib	sibling
SICU	surgical intensive care unit
SIDS	sudden infant death syndrome
Sig	write on label
SL	sublingual
SLE	systemic lupus erythematosus
sol	solution, dissolved
sos	if necessary
sp gr, SG, sg	specific gravity
Sub-Q, subQ	Subcutaneous
SpCO	saturated pressure carbon monoxide
SpMet	saturated pressure methemoglobin
SSS	sick sinus syndrome, specific soluble substance, short-stay surgery
stat	immediately
STD	sexually transmitted disease
STEMI	ST elevation myocardial infarction
susp	suspension
T_3	triiodothyronine
T_4	tetraiodothyronine
T&A	tonsillectomy and adenoidectomy
TAH	total abdominal hysterectomy
TB, TBC	tuberculosis
TCP	transcutaneous pacing
TdP	torsades de pointes
Tdap	tetanus, diphtheria, acellular pertussis
TIA	transient ischemic attack
TIBC	total iron-binding capacity
TID	three times a day
TKO	to keep open
TPN	total parenteral nutrition
TPR	temperature, pulse, and respirations
UA	Unstable angina; urinalysis
URI	upper respiratory infection
UTI	urinary tract infection
VC	vital capacity
VD	venereal disease
VDH	valvular disease of the heart
VDRL	Venereal Disease Research Laboratory (test for syphilis)
VF	ventricular fibrillation
VS	vital signs
VSD	ventricular septal defect
V_T	tidal volume
VF	ventricular fibrillation
VT	ventricular tachycardia
WBC	white blood cell, white blood count
WNL	within normal limits
WPW	Wolff-Parkinson White

*Adapted From Potter PA, Perry AG: Basic nursing: essentials for practice, ed 6, St Louis, 2007, Mosby.

TABLE 9-7 The Joint Commission's "Do Not Use" Abbreviations List

OFFICIAL ''DO NOT USE'' LIST*

Do Not Use	Potential Problem	Use Instead
U (unit)	Mistaken for ''0'' (zero), the number ''4'' (four) or ''cc''	Write ''unit''
IU (International Unit)	Mistaken for IV (intravenous) or the number 10 (ten)	Write ''International Unit''
Q.D., QD, q.d., qd (daily)	Mistaken for each other	Write ''daily''
Q.O.D., QOD, q.o.d., qod (every other day)	Period after the Q mistaken for ''I'' and the ''O'' mistaken for ''I''	Write ''every other day''
Trailing zero (X.0 mg)†	Decimal point is missed	Write X mg
Lack of leading zero (.X mg)		Write 0.X mg
MS	Can mean morphine sulfate or magnesium sulfate	Write ''morphine sulfate''
MSO_4 and $MgSO_4$	Confused for one another	Write ''magnesium sulfate''

ADDITIONAL ABBREVIATIONS, ACRONYMS, AND SYMBOLS (FOR POSSIBLE FUTURE INCLUSION IN THE OFFICIAL ''DO NOT USE'' LIST)

Do Not Use	Potential Problem	Use Instead
> (greater than)	Misinterpreted as the number ''7'' (seven) or the letter ''L''	Write ''greater than''
< (less than)	Confused for one another	Write ''less than''
Abbreviations for drug names	Misinterpreted due to similar abbreviations for multiple drugs	Write drug names in full
Apothecary units	Unfamiliar to many practitioners Confused with metric units	Use metric units
@	Mistaken for the number ''2'' (two)	Write ''at''
Cc	Mistaken for U (units) when poorly written	Write ''mL'' or ''milliliters''
µg	Mistaken for mg (milligrams) resulting in 1000-fold overdose	Write ''mcg'' or ''micrograms''

Joint Commission on Accreditation of Healthcare Organizations, 2010.http://www.jointcommission.org/assets/1/18/Official_Do%20Not%20Use_List_%206_10.pdf. Accessed 4-19-11

*Applies to all orders and all medication-related documentation that is handwritten (including free-text computer entry) or on preprinted forms.

†**Exception:** A ''trailing zero'' may be used only where required to demonstrate the level of precision of the value being reported, such as for laboratory results, imaging studies that report size of lesions, or catheter/tube sizes. It may not be used in medication orders or other medication-related documentation.

TABLE 9-8 Guide to Pronunciation of Medical Terms

The following is a simple guide for practicing the pronunciation of medical terms. The pronunciations are only approximate; however, they are adequate to meet the needs of the beginning student.

In respelling for pronunciation, words are minimally distorted to indicate phonetic sound.

Example:

doctor (dok-tor)
gastric (gas-trik)

A special mark, called the *macron* (¯), is used to indicate long vowel sounds.

Example:

donate (dō-nāt)
hepatoma (hep-a-tō-ma)

ā as in *ate, say*
ē as in *eat, beet, see*
ī as in *I, mine, sky*
ō as in *oats, so*
ū as in *unit, mute*

Vowels with no markings have the short sound.

Continued

TABLE 9-8 Guide to Pronunciation of Medical Terms—cont'd

Example:
discuss (dis-kus)
medical (med-i-kal)
a as in *at, lad*
e as in *edge, bet*
i as in *itch, wish*
o as in *ox, top*
u as in *sun, come*

An accent mark indicates the stress on a certain syllable. The primary accent is indicated by capital letters, and the secondary accent (which is stressed but not as strongly as the primary accent) is indicated by italics.

Example:
altogether (*all*-tū-GETH-er)
pancreatitis (*pan*-krē-a-TĪ-tis)

From LaFleur Brooks M: *Exploring medical language,* ed 7, St Louis, 2009, Mosby.

example is *angina* (an′ jin a) with the emphasis on the first syllable and a short i and (an jin′ a) with the emphasis on the second syllable and a long i. Some medical terms look alike and sound alike but have very different meanings.

NOTE
Paramedics who can spell a medical term accurately usually can also pronounce it correctly.

The pronunciation of medical terms is best perfected by using the word frequently and by saying the word aloud. If the paramedic is unsure of any word, the correct spelling and pronunciation should be checked in a medical dictionary.

DID YOU KNOW?
Confusing Medical Terms
Some medical terms look alike and sound alike, but have very different meanings. Some common ones that are easily confused include:

- **Arterio** means artery. **Athero** means plaque or fatty substance**. Arthro** means joint.
- **Ileum** is a part of the small intestine. **Ilium** means part of the hip bone.
- **Mucous** means resembles mucus. **Mucus** is the substance secreted from the membranes.
- **Myco** means fungus. **Myelo** means both bone marrow and spinal cord. **Myo** means muscle.
- **Palpation** is an examination technique. **Palpitation** means a pounding racing heart.
- **Pyelo** means the renal pelvis. **Pyo** means pus.
- **Viral** means a virus. **Virile** means having masculine traits.

SUMMARY

- Medical terminology is the language of medicine. It is important to know the language to interpret patient information and communicate it to other health care personnel.
- Medical terms are used to describe body structures, systems, and functions; anatomical regions and locations; diseases and other health problems; medical and surgical procedures; diagnostic tests; and medical instruments.
- Medical terms are broken down into several parts. These parts include prefixes, suffixes, root words, and some combining vowels.
- A prefix is a root syllable at the beginning of a word that describes location or intensity.
- A suffix comes at the end of a word and describes a condition or diagnosis.
- Root words describe a structure or condition. Root words may be combined with other root words, a prefix, and/or a suffix.
- Combining vowels join syllables in medical terms to make them easier to pronounce.
- Medical terms are interpreted by analyzing each word part and then combining them to determine the meaning.
- Specific rules govern the conversion of medical terms from the singular form to the plural form. For example, *vertebra* becomes *vertebrae; diagnosis* becomes *diagnoses; phalanx* becomes *phalanges;* and *alveolus* becomes *alveoli.*
- Medical abbreviations, acronyms, and symbols are a form of medical shorthand. It is important for paramedics to use the abbreviations approved within their EMS system.
- Paramedics must be able to pronounce medical terms correctly so that their intended meaning is communicated clearly.

CHAPTER

10 Review of Human Systems

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Discuss the importance of human anatomy as it relates to the paramedic profession.
2. Describe the anatomical position.
3. Properly interpret anatomical directional terms and body planes.
4. List the structures that compose the axial and appendicular regions of the body.
5. Define the divisions of the abdominal region.
6. List the three major body cavities.
7. Describe the contents of the three major body cavities.
8. Discuss the functions of the following cellular structures: the cytoplasmic membrane, the cytoplasm (and organelles), and the nucleus.
9. Describe the process by which human cells reproduce.
10. Differentiate and describe the following tissue types: epithelial tissue, connective tissue, muscle tissue, and nervous tissue.
11. For each of the 11 major organ systems in the human body, label a diagram of anatomical structures; list the functions of the major anatomical structures; and explain how the organs of the system interrelate to perform the specific functions of that system.
12. For the special senses, label a diagram of the anatomical structures of the special senses; list the functions of the anatomical structures of each sense; and explain how the structures of the senses interrelate to perform their specialized functions.

KEY TERMS

abdominal aorta The portion of the descending aorta that passes from the aortic hiatus of the diaphragm into the abdomen, where it divides into the two common iliac arteries.

acetabulum The large, cup-shaped articular cavity at the juncture of the ilium, the ischium, and the pubis that contains the ball-shaped head of the femur.

action potential A change in membrane potential in an excitable tissue that acts as an electrical signal and is propagated in an all-or-none fashion.

adenosine triphosphate (ATP) A nucleotide composed of adenosine, an organic base, with three phosphate groups attached to it; it stores energy in muscles.

adipose tissue A specialized connective tissue that stores lipids; also known as *fat tissue.*

aerobic oxidation A biochemical reaction that increases the positive charges on an atom or the loss of negative charges in the presence of oxygen.

afferent division The division of the peripheral nervous system that transmits impulses from the periphery to the central nervous system.

afferent neurons Neurons that carry action potentials from the periphery to the CNS.

aldosterone A steroid hormone produced by the adrenal cortex to regulate the sodium and potassium balance in the blood.

alveoli Minute air sacs in the lungs through which gas exchange takes place between alveolar air and pulmonary capillary blood.

amino acids Organic chemical compounds composed of one or more basic amino groups and one or more acidic carboxyl groups.

antidiuretic hormone (ADH) A hormone produced in the posterior pituitary gland that regulates the balance of water in the body by accelerating the resorption of water.

anus The distal end or outlet of the rectum.

aorta The main and largest artery in the body.

anatomical position The position of standing erect with the feet and palms facing the examiner.

anterior The front, or ventral, surface.

appendicular region The region comprised of the limbs, or extremities.

appendicular skeleton The bones of the upper and lower extremities.

aqueous humor The clear, watery fluid that circulates in the anterior and posterior chambers of the eye.

arachnoid layer The delicate, weblike, middle membrane that covers the brain.

areola The circular, pigmented area surrounding the nipple.

areolar connective tissue A loose tissue that consists of delicate webs of fibers and a variety of cells embedded in a matrix of soft, sticky gel.

arterioles Small branches of arteries.
arteriovenous anastomoses Vessels that allow blood to flow from arteries to veins without passing through capillaries; also known as *arteriovenous shunts*.
atrial natriuretic factor (ANF) A peptide released from the atria when atrial blood pressure is increased; it lowers blood pressure by increasing urine production, thus reducing blood volume.
atrioventricular node An area of specialized cardiac muscle that receives the cardiac impulse from the sinoatrial node and conducts it to the bundle of His.
atrioventricular valve A valve in the heart through which blood flows from the atria to the ventricles.
auricle The part of the external ear that protrudes from the head; also known as the *pinna*.
autonomic nervous system The division of the peripheral nervous system that acts as a control system for visceral processes; it functions largely below the level of consciousness.
autonomic reflex Any of a large number of normal reflexes governing and regulating the functions of the viscera
autophagia A condition in which the body obtains nutrition through consumption of its own tissues.
axial region The region comprised of the head, neck, thorax, and abdomen.
axial skeleton The bones of the head, neck, and torso.
bacteria Single-celled microorganisms that cause an infection characteristic of that species.
basophils White blood cells that promote inflammation; they readily stain with specific dyes.
bicuspid valve One of the two atrioventricular valves located between the left atrium and ventricle; also known as the mitral valve.
bile A bitter, yellow-green secretion of the liver that is stored in the gallbladder.
blood The fluid and its suspended, formed elements that circulate through the heart, arteries, capillaries, and veins.
bone A highly specialized form of hard, connective tissue; it consists of living cells and mineralized matrix.
bony labyrinth Part of the inner ear; it contains the membranous labyrinth.
Bowman's capsule The expanded beginning of a renal tubule.
bronchioles Small branches of the bronchi.
bulbourethral glands Small glands located just below the prostate gland that lubricate the terminal portion of the urethra and contribute to seminal fluid; also known as Cowper's glands.
bundle of His A band of fibers in the myocardium through which the cardiac impulse is transmitted from the atrioventricular node to the ventricles.
calcaneus The heel bone, the largest of the tarsal bones.
cancellous bone Lattice like tissue normally present in the interior of many bones where spaces usually are filled with marrow; also known as *spongy bone*.
capillaries Tiny vessels that connect arterioles to venules.
cardiac muscle A special striated muscle of the myocardium that contains dark, intercalated disks at the junctions of the abutting fibers; it is characterized by special contractile abilities.
cardiac output The volume of blood pumped each minute by the ventricle.
cardiac sphincter A ring of muscle fibers at the juncture of the esophagus and stomach.
carina A downward and backward projection of the lowest tracheal cartilage, forming a ridge between the openings of the right and left primary bronchi.
carpal bones The bones of the carpus, or wrist.
cartilage Firm, smooth, nonvascular connective tissue.
cartilaginous joints Joints that are slightly movable.
cecum A cul-de-sac constituting the first part of the large intestine.
cell The functional basic unit of life.
central nervous system (CNS) The system composed of the brain and spinal cord.
centrioles Usually paired organelles that lie in the centrosome.
centrosome A specialized zone of cytoplasm close to the nucleus that contains two centrioles.
cerebellum The second largest part of the brain; it plays an essential role in producing normal movements.
cerebral cortex A thin layer of gray matter, made up of neuron dendrites and cell bodies, that comprises the surface of the cerebrum.
cerebrospinal fluid (CSF) The fluid that fills the subarachnoid space in the brain and spinal cord and is found in the cerebral ventricles.
cerebrum The largest and uppermost part of the brain; it controls consciousness, memory, sensations, emotions, and voluntary movements.
cervix The lower part of the uterus.
chromatin granules The material within the cell nucleus from which chromosomes are formed.
chromosomes Organized structures of deoxyribonucleic acid (DNA) and protein that are found in cells.
chyme The semifluid mass of partly digested food passed from the stomach into the duodenum.
cilia Small, hairlike processes on the outer surfaces of some cells.
clitoris Erectile tissue in the vestibule of the vagina.
compact bone Hard, dense bone that usually is found at the surface of skeletal structures, as distinguished from cancellous bone.
conjunctiva A mucous membrane that covers the anterior surface of the eyeball and the lining of the eyelids.
connective tissue Tissue that supports and binds other body tissues and parts.
cornea The convex, transparent, anterior part of the eye.
coronary arteries The two arteries that arise from the base of the aorta and carry blood to the muscle of the heart.
costal cartilages Cartilages that connect the sternum and the ends of the ribs; they allow the chest to move in respiration.

coxae The hip joints; the head of the femur and the acetabulum of the innominate bone.
cranial vault The eight skull bones that surround and protect the brain; the brain case.
cricoid cartilage The most inferior laryngeal cartilage.
cricothyroid membrane The membrane joining the thyroid and cricoid cartilages.
cytoplasm All of the substance of a cell other than the nucleus
cytoplasmic membrane The plasma membrane.
deoxyribonucleic acid (DNA) A type of nucleic acid that comprises the genetic material of cells.
dermatome The skin surface area supplied by a single spinal nerve.
dermis Dense, irregular connective tissue that forms the deep layer of the skin.
diaphragm The dome-shaped, musculofibrous partition that separates the thoracic and abdominal cavities.
diaphysis The shaft of a long bone, consisting of a tube of compact bone that encloses the medullary cavity.
diencephalon The parts of the brain between the cerebral hemispheres and the mesencephalon
differentiation A process in which cells become specialized in one type of function or act in concert with other cells to perform a more complex task.
dorsal root A sensory component that conveys afferent nerve processes to the spinal cord.
ductus deferens A thick, smooth muscular tube that allows sperm to exit from the epididymis through the ejaculatory duct; also known as the *vas deferens*.
duodenum The first subdivision of the small intestine.
dura mater The outermost layer of the meninges.
efferent division The division of the peripheral nervous system that transmits action potentials from the central nervous system to effector organs such as muscles and glands
efferent neurons Neurons that carry impulses away from the central nervous system to the periphery.
electrolytes Cations or anions in solution that conduct an electrical current.
endocrine glands Glands that secrete hormones into the blood rather than through a duct.
endocrine system A collection of glands that produce and secrete hormones.
endoplasmic reticulum A network of connecting sacs or canals that wind through the cytoplasm of a cell, serving as a miniature circulatory system for the cell.
enzymes A protein produced by living cells that catalyzes chemical reactions in organic matter.
eosinophil A white blood cell that inhibits inflammation; it readily stains with acidic dyes.
epicardium The portion of the serous pericardium that covers the heart's surface; also known as the *visceral pericardium*.
epidermis The outer portion of the skin; it is formed of epithelial tissue that rests on or covers the dermis.
epididymis A tightly coiled tube, lying along the top of and behind the testes, where sperm matures.
epidural space The space above or on the dura.
epiglottis A lidlike cartilage that overhangs the entrance to the larynx.
epiphyseal plate The site of bone elongation; also known as the *growth plate*.
epithelial tissue The cellular covering of internal and external surfaces of the body, including the lining of vessels and other small cavities.
erection The condition of hardness, swelling, and elevation observed in the penis and to a lesser degree in the clitoris, usually caused by sexual arousal.
erythrocytes Red blood cells.
esophagus The muscular canal extending from the pharynx to the stomach.
eukaryotes Cells with a true nucleus; they are found in all higher organisms and in some microorganisms.
eustachian tube The auditory canal; it extends from the middle ear to the nasopharynx; also known as the auditory tube.
exocrine gland A gland that secretes chemicals and hormones into a duct.
external ear The portion of the ear that includes the auricle and external auditory meatus; it terminates at the eardrum.
extracellular matrix Nonliving chemical substances located between connective tissue cells.
extracellular Occurring outside a cell or cell tissues or in cavities or spaces between cell layers or groups of cells.
femur The thigh bone, which extends from the pelvis to the knee; the largest and strongest bone in the body.
fibrous connective tissue A connective tissue that consists mainly of bundles of strong, white collagenous fibers arranged in parallel rows.
fibrous joints Joints that are immovable.
fibula The bone of the leg, lateral to and smaller than the tibia.
flat bones Bones that have a thin, flattened shape, such as certain skull bones, the ribs, the sternum, and the scapulae.
gallbladder A pear-shaped excretory sac on the visceral surface of the right lobe of the liver; it serves as a reservoir for bile.
ganglia A group of nerve cell bodies in the peripheral nervous system.
glomerulus The mass of capillary loops at the beginning of each nephron.
glottic opening The vocal cords and the space between them.
glycoproteins A large group of conjugated proteins in which the nonprotein substance is a carbohydrate.
Golgi apparatus Specialized endoplasmic reticulum that concentrates and packages materials for secretion from the cell.
gray matter The gray tissue that makes up the inner core of the spinal column.

hemoglobin A complex protein-iron compound in the blood that carries oxygen to the cells from the lungs and carbon dioxide away from the cells to the lungs.
hematopoietic tissue Tissue related to the process of formation and development of various types of blood cells.
hepatic artery The branch of the aorta that delivers blood to the liver.
histamine An amine released by mast cells and basophils that promotes inflammation.
homeostasis A state of equilibrium in the body with respect to functions and composition of fluids and tissues.
humerus The largest bone of the upper arm, comprising a body, head, and condyle.
hymen A mucous membrane that may partly or entirely occlude the vaginal outlet.
hyoid bone The U-shaped bone between the mandible and the larynx.
hypothalamus A portion of the diencephalon of the brain that activates, controls, and integrates the peripheral autonomic nervous system, endocrine processes, and many somatic functions, such as body temperature, sleep, and appetite.
ileum The distal portion of the small intestine.
iliac crest The upper free margin of the ilium.
ilium One of the three bones that make up the innominate bone.
inferior Toward the feet; below a point of reference in the anatomical position.
inferior vena cava The vein that returns blood from the lower limbs and the greater part of the pelvic and abdominal organs to the right atrium.
inflammatory response A tissue reaction to injury or an antigen; it may include pain, swelling, itching, redness, heat, and loss of function.
inguinal canal The passage through the lower abdominal wall that transmits the spermatic cord in the male and the round ligament in the female.
inner ear The part of the ear that contains the sensory organs for hearing and balance
integumentary system The largest organ system in the body, consisting of the skin and accessory structures.
intercellular Occurring between or among cells.
interstitial fluid Fluid that occupies the space outside the blood vessels and/or outside the cells of an organ or tissue.
intracellular Occurring within cell membranes.
intraocular pressure Pressure within the eye that keeps the eye inflated.
ions Atoms or groups of atoms that carry a charge of electricity by virtue of having gained or lost one or more electrons.
iris The colored contractile membrane of the eye that can be seen through the cornea.
irregular bones Bones that are not representative of the other three categories (long, short, or flat bones).
ischium One of the three parts of the hipbone; it joins the ilium and the pubis to form the acetabulum.
jejunum One of the three portions of the small intestine.
joint capsule A well-defined structure that encloses a joint.
jugular notch The superior margin of the manubrium; it is palpated easily at the anterior base of the neck; also known as the *suprasternal notch*.
kidney One of the pair of organs that cleanse the body of the waste products continually produced by metabolism.
Krebs cycle A sequence of enzymatic reactions, involving the metabolism of carbon chains of sugar, fatty acids, and amino acids, that yield carbon dioxide, water, and high-energy phosphate bonds.
lacrimal gland The tear gland located in the superolateral corner of the orbit.
large intestine The portion of the digestive tract comprising the cecum; the appendix; the ascending, transverse, and descending colons; and the rectum.
laryngopharynx The lowest part of the pharynx.
larynx The voice box, located just below the pharynx.
lateral recumbent A position in which the patient lies on the right or left side.
left atrium One of the four chambers of the human heart; the left atrium receives oxygenated blood from the lungs and pumps it into the left ventricle.
lens The crystalline portion of the eye.
leukocytes White blood cells.
limbic system The part of the brain involved with emotions and olfaction.
lipid bilayer The central layer of the cytoplasmic membrane; it is composed of a double layer of lipid molecules.
lipoproteins Conjugated proteins in which lipids form an integral part of the molecule; lipoproteins are synthesized primarily in the liver.
liver An organ in the upper abdomen that aids in digestion and removes waste products and cellular debris from the blood; the largest solid organ in the human body.
long bones Bones that are longer than they are wide, such as the humerus, ulna, radius, femur, tibia, fibula, and phalanges.
loop of Henle The U-shaped portion of the renal tubule.
lymph nodes Encapsulated masses of lymphoid tissue found among lymph vessels.
lymph nodules Small, densely packed spherical nodes or aggregations of lymph cells embedded in the reticular meshwork of the lymphatic system; they are found mainly in the tonsils, spleen, and thymus.
lymphatic system The network of vessels, ducts, nodes, valves, and organs involved in protecting and maintaining the internal fluid environment of the body.
lymphocytes A type of white blood cell formed in lymphoid tissue.
lysosomes Membranous-walled organelles that contain enzymes, which enable the lysosome to function as an intracellular digestive system.
macrophages Phagocytic cells in the immune system.

mammary glands External accessory sex organs in females; the breasts.
medial malleolus The rounded process on the medial side of the ankle joint.
mediastinum The area of the body that includes the trachea, esophagus, thymus, heart, and great vessels.
medulla The lowest part of the brainstem, which controls vital functions; an enlarged extension of the spinal cord; also known as the *medulla oblongata*.
meninges Fluid-containing membranes surrounding the brain and spinal cord.
mesencephalon One of the three parts of the brainstem; also known as the *midbrain*.
mesentery Connective tissue that holds some of the abdominal organs to the body wall.
metabolism The culmination of all chemical processes that take place in living organisms.
metacarpals The five bones that extend from the carpus to the phalanges.
metatarsals The five bones that comprise the metatarsus.
middle ear An air-filled space in the temporal bone that contains the auditory ossicles.
mitochondria Small, spherical, rod-shaped or thin filamentous structures in the cytoplasm of cells; a site of adenosine triphosphate production.
mitosis Cell division that results in two daughter cells with exactly the same number and type of chromosomes as the mother cell.
monocytes A type of white blood cell found in the lymph nodes, spleen, bone marrow, and loose connective tissue.
mons pubis The prominence caused by a pad of fatty tissue over the symphysis pubis in the female.
motor neuron A neuron that innervates skeletal, smooth, or cardiac muscle fibers; also known as an *interneuron*.
mucus The viscous, slippery secretion of mucous membranes and glands.
mycoplasma A genus of microscopic organisms that lack rigid cell walls; mycoplasma are considered the smallest free-living organisms.
myofilaments Extremely fine, molecular, threadlike structures that help form the myofibril of muscle; thick myofibrils are formed of myosin, and thin myofilaments are formed of actin.
nephron The functional unit of the kidney.
neuroglia The supporting or nonneuronal tissue cells of the central and peripheral nervous system.
neurons The functional units of the nervous system, consisting of the nerve cell body, the dendrites, and the axon.
neutrophils Small, phagocytic white blood cells with a lobed nucleus and small granules in the cytoplasm; neutrophils stains readily with neutral dyes.
nucleoplasm The protoplasm of the nucleus, as contrasted with that of the cell.
nucleus The central controlling body within a living cell.
obturator foramen A large opening on each side of the lower portion of the hipbone, formed posteriorly by the ischium, superiorly by the ilium, and anteriorly by the pubis.
oculomotor nerve The third cranial nerve, which contains sensory and motor fibers; it provides for movement in most of the muscles of the eye, for constriction of the pupil, and for accommodation of the eye to light.
olfactory Of or pertaining to the sense of smell.
oocytes Incompletely developed ova.
optic nerve The nerve that carries visual signals from the eye to the crossing of the optic tracts.
organ A structure made up of two or more kinds of tissues organized to perform a more complex function than any one tissue alone.
organelles Various particles of living substance that are bound within most cells, such as the mitochondria, the Golgi apparatus, the endoplasmic reticulum, the lysosomes, and the centrioles.
ovarian follicles Spherical cell aggregations in the ovary that contain an oocyte.
ovaries The pair of female gonads found on each side of the lower abdomen beside the uterus.
pancreas A fish-shaped, nodular gland located across the posterior abdominal wall in the epigastric region of the body; it secretes various substances, including digestive enzymes, insulin, and glucagon.
parasympathetic nervous system The subdivision of the autonomic nervous system, usually involved in activating vegetative functions such as digestion, defecation, and urination.
parietal peritoneum The serous membrane that covers the body cavity wall.
patella A flat, triangular bone at the front of the knee joint; the kneecap.
penis The external reproductive organ of the male.
pericardial sac The sac that surrounds the heart.
perineum The pelvic floor and associated structures occupying the pelvic outlet, bounded anteriorly by the pubic symphysis, laterally by the ischial tuberosities, and posteriorly by the coccyx.
periosteum Tough connective tissue that covers the bone.
peripheral nervous system A subdivision of the nervous system consisting of nerves and ganglia.
phagocytosis The process by which cells ingest solid substances, such as other cells, bacteria, bits of necrosed tissue, and foreign particles.
phalanges Any bone of a finger or toe.
phospholipids A class of compounds, widely distributed in living cells, that contain phosphoric acid, fatty acids, and a nitrogenous base.
pia mater The innermost layer of the meninges; it directly covers the brain.
pituitary gland A small gland attached to the hypothalamus; it supplies numerous hormones that govern many vital processes.
plasma membrane The outer covering of a cell that contains the cellular cytoplasm; also known as the *cell membrane*.

platelet A fragment of a cell; it contains granules in the central part and clear protoplasm peripherally but has no definite nucleus.

pleural cavity The area of the body that surrounds the lungs.

pleural space The potential space between the visceral and parietal layers of the pleura.

polysaccharides Carbohydrates that contain three or more molecules of simple carbohydrate.

pons The part of the brainstem between the medulla and midbrain.

portal vein A vein that branches like an artery in the liver and ends in capillary-like sinusoids that convey the blood to the inferior vena cava through the hepatic veins.

posterior The back, or dorsal, surface.

precapillary sphincter The smooth muscle sphincter that regulates blood flow through a capillary.

prokaryotes Cells without a true nucleus; instead, nuclear material is scattered throughout the cytoplasm.

prone A position in which the patient lies on the stomach (face down).

prostate gland The gland that lies just below the male bladder; its secretion is one of the components of semen.

puberty The period of life when the ability to reproduce begins.

pubis One of a pair of pubic bones that, with the ischium and the ilium, form the hipbone and join the pubic bone from the opposite side at the pubic symphysis.

pulmonary surfactant Certain lipoproteins that reduce the surface tension of pulmonary fluids, allowing the exchange of gases in the alveoli of the lungs and contributing to the elasticity of pulmonary tissue.

pulmonary trunk The large elastic artery that carries blood from the right ventricle of the heart to the right and left pulmonary arteries.

pulmonary veins The veins that carry oxygenated blood from the lung to the left atrium.

pupil The opening in the center of the iris that regulates the amount of light entering the eye.

Purkinje fibers Myocardial fibers that are a continuation of the bundle of His and that extend into the muscle walls of the ventricles.

radius One of the bones of the forearm; it lies parallel to the ulna.

rectum The segment of the large intestine continuous with the descending sigmoid colon just proximal to the anal canal.

red marrow Specialized soft tissue found in many bones of infants and children; in the spongy bone of the proximal epiphyses of the humerus and femur; and in the sternum, ribs, and vertebral bodies of adults. It is essential in the manufacture of red blood cells.

renal pyramids Pyramidal masses seen on longitudinal section of the kidney; they contain part of the loop of Henle and the collecting tubules.

respiration The process of the molecular exchange of oxygen and carbon dioxide in the body's tissues.

reticular activating system A functional system in the brain that is essential for wakefulness, attention, concentration, and introspection.

reticular formation A small, thick cluster of neurons nestled in the brainstem that controls breathing, the heartbeat, blood pressure, level of consciousness, and other vital functions.

retina The nervous tunic of the eye; it is continuous with the optic nerve.

retroperitoneal Behind the peritoneum.

ribonucleic acid (RNA) A nucleic acid found in the nucleus and the cytoplasm of cells that transmits genetic instructions from the nucleus to the cytoplasm. In the cytoplasm, RNA functions in the assembly of proteins.

ribosome The "factory" of a cell, in which protein is synthesized.

right atrium One of the four chambers of the human heart; it receives deoxygenated blood from the body through the vena cava and pumps it into the right ventricle.

sarcomere The contractile unit of skeletal muscle; it contains thick and thin myofilaments.

sclera The opaque membrane covering the eyeball.

scrotum The sac of skin that contains the testes.

sebaceous glands Glands of the skin, usually associated with a hair follicle, that produce sebum.

sebum The secretion of sebaceous glands; it prevents drying and protects against some bacteria.

semen The male reproductive fluid.

seminal vesicle One of two glandular structures that empty into the ejaculatory ducts; its secretion is one of the components of semen.

septum A thin wall dividing two cavities or masses of soft tissue.

serum Blood plasma without its clotting factors.

short bones Bones that are approximately as broad as they are long, such as the carpal bones of the wrist and the tarsal bones of the ankle.

sinoatrial node An area of specialized heart tissue that generates the cardiac electrical impulse.

sinuses The cavities in the bones of the skull that connect to the nasal cavities by small channels.

skeletal muscle Muscle tissue that appears microscopically to consist of striped myofibrils; also known as *striated muscle* and *voluntary muscle.*

small intestine The longest portion of the digestive tract; it is divided into the duodenum, jejunum, and ileum.

smooth muscle One of two kinds of muscle; it is composed of elongated, spindle-shaped cells in muscles not under voluntary control, such as smooth muscle of the intestines, stomach, and other visceral organs; also known as *visceral muscle, involuntary muscle,* and *nonstriated muscle.*

somatic nervous system The part of the nervous system composed of nerve fibers that send impulses from the central nervous system to skeletal muscle.

somatomotor neurons Neurons that innervate skeletal muscles.

spermatogenesis The process of development of spermatozoa.
spermatozoa The male sex cells, which are composed of a head and a tail; sperm contains genetic information transmitted by the male.
spinal nerve One of 31 pairs of nerves formed by the joining of the dorsal and ventral routes that arise from the spinal cord.
spleen A large, highly vascular lymphatic organ situated in the upper part of the abdominal cavity between the stomach and the diaphragm; it responds to foreign substances in the blood, destroys worn-out erythrocytes, and is a storage site for red blood cells.
sternal angle The point at which the manubrium joins the body of the sternum; also known as the *angle of Louis*.
sternoclavicular joint The double gliding joint between the sternum and the clavicle.
sternomanubrial joint The point at which the manubrium joins the body of the sternum; also known as the sternal angle or angle of Lewis.
sternum The elongated, flattened bone that forms the middle portion of the thorax.
subarachnoid space The area below the arachnoid membrane but above the pia mater that contains cerebrospinal fluid.
subclavian vein The continuation of the axillary vein in the upper body; it extends from the lateral border of the first rib to the sternal end of the clavicle, where it joins the internal jugular to form the brachiocephalic vein.
subcutaneous tissue The adherent layer of adipose tissue just below the dermal layer; also known as the *hypodermis*.
subdural space The space between the dura mater and the arachnoid.
superior Situated above or higher than a point of reference in the anatomical position.
superior vena cava The vein that returns blood from the head and neck, upper limbs, and thorax to the right atrium.
supine A position in which the patient lies on the back (face up).
sweat glands Glands that produce sweat or viscous organic secretions; also known as *sudoriferous glands*.
sympathetic nervous system A subdivison of the autonomic nervous system that usually is involved in preparing the body for physical activity.
symphysis pubis The joint that connects the coxal bones of the pelvis.
synapse Functional membrane-to-membrane contact of a nerve cell with another nerve cell, muscle cell, gland cell, or sensory receptor; it serves to transmit action potentials from one cell to another.
synovial joints Joints that are freely movable.
system Interconnected functions or organs in which a stimulus or an action in one area affects all other areas.
tarsal bones The bones of the ankle.
taste buds The peripheral taste organs that are distributed over the tongue and the roof of the mouth.
testes The male gonads, which produce the male sex cells, or sperm.
thalamus Tissue located just above the hypothalamus; it helps to produce sensations, associates sensations with emotions, and plays a part in arousal.
thymus A single, unpaired gland located in the mediastinum; the primary central gland of the lymphatic system.
thyroid membrane The fibrous membrane that joins the hyoid and the thyroid cartilages.
tibia The second longest bone of the skeleton; it is located at the medial side of the leg.
tonsils Large collections of lymphatic tissue beneath the mucous membrane of the oral cavity and pharynx.
trachea A cylindrical tube in the neck composed of cartilage and membrane; it conveys air to the lungs.
tricuspid valve The valve located between the right atrium and ventricle.
tunic One of the enveloping layers of a part; one of the coats of a blood vessel; one of the coats of the eye; one of the coats of the digestive tract.
tympanic membrane The cellular membrane that separates the external ear from the middle ear; also known as the *eardrum*.
ulna One of the bones of the forearm.
ureters A pair of tubes that carry the urine from the kidneys into the bladder.
urethra A small tubular structure that drains urine from the bladder; in men, it also serves as a passageway for semen during ejaculation.
urinary bladder The muscular, membranous sac in the pelvis that stores urine for discharge through the urethra.
uterine tubes A pair of ducts that open at one end into the uterus and at the other end into the peritoneal cavity, over the ovary; also known as the *fallopian tubes*.
uterus The hollow, pear-shaped internal female organ of reproduction.
uvula The cone-shaped process hanging down from the soft palate that helps prevent food and liquid from entering the nasal cavities.
vagina The part of the female genitalia that forms a canal from the orifice through the vestibule to the uterine cervix.
vascular tunic The choroid, ciliary body, and iris.
ventral root The nerve that conveys efferent nerve processes away from the spinal cord.
ventricles Small cavities; the term usually refers to the right and left ventricles of the heart.
viruses Minute, parasitic microorganisms without independent metabolic activity that can replicate only within a cell of a living plant or animal host.
visceral peritoneum The serous membrane that covers the abdominal organs.
visceral reflex A reflex mediated by autonomic nerves and initiated in the viscera

vitreous humor The transparent, jellylike material that fills the space between the lens and the retina.

vocal cords The two folds of elastic ligaments covered by mucous membrane that stretch from the thyroid cartilage to the arytenoid cartilage; vibration of the vocal cords is responsible for voice production; also known as the *true vocal cords*.

vulva The external genitalia of the female.

xiphoid process The smallest of three parts of the sternum; it articulates caudally with the body of the sternum and laterally with the seventh rib.

yellow marrow Specialized soft tissue (mainly adipose) found in the compact bone of most adult epiphyses.

Human anatomy is the study of how the human body is organized. The paramedic must know anatomy to assess a patient by body region. This knowledge also helps the paramedic communicate well with other members of the health care team.

TERMINOLOGY

Directional terms used by medical professionals refer to the human body in the **anatomical position**. This position describes a person standing erect with the feet and palms facing the examiner. A patient in the **supine** position is lying on the back (face up). A patient in the **prone** position is lying on the stomach (face down). A patient in the **lateral recumbent** position is lying on the right or left side. Regardless of the patient's position, the paramedic should always report patient information with reference to the anatomical position (Figure 10-1).[1]

Directional terms, such as *up* or *down*, *front* or *back*, and *right* or *left*, also are expressed in anatomical terminology (Table 10-1). The terms always refer to the patient, not the examiner (e.g., the patient's left arm).

(Courtesy Florissant Valley Fire Protection District, Florissant, Mo.)

SHOW ME THE EVIDENCE

Walters and colleagues sought to develop a program that would both introduce medical students to continuing education and enhance paramedics' knowledge of anatomy. They chose anatomy because paramedics have some previous knowledge of the subject, and the researchers thought that this knowledge could help the paramedics predict injury based on external physical findings in trauma cases. Five medical students provided anatomy education to 19 paramedics using case-based instruction and cadaver laboratories. At the conclusion, all the paramedics passed the post test and reported above average satisfaction with the program. A survey was performed 3 months later, and the mean paramedic scores indicated that the paramedics believed the course had very likely or absolutely affected their patient care and understanding of injury.

Walters WA, Bailey H, Kaplan L: Can preclinical medical students be integrated into the continuing medical education process by instructing prehospital care providers? *Am J Surg* 179:229-233, 2000.

Anatomical Planes

The relationships of internal body structures are classified into anatomical planes. These planes may be viewed as imaginary straight-line divisions of the human body (Figure 10-2). The *sagittal plane* runs vertically through the middle of the body, creating right and left sections. A plane that is to one side of the midline is said to be *parasagittal*. The transverse (or horizontal) plane divides the body into top and bottom sections. These are known as **superior** and **inferior** sections. The frontal (or coronal) plane divides the body into front and back. These are known as **anterior** and **posterior** sections.

Body Regions

The human body is divided into a number of regions.[2] This division helps to organize anatomical structures. The **appendicular region** is made up of the limbs, or extremities. The **axial region** is made up of the head, neck, thorax, and abdomen. The abdomen usually is divided into four quadrants: the upper right, lower right, upper left, and

FIGURE 10-1 Anatomical position. A person in the anatomical position stands with the feet and the palms of the hands facing forward with the thumbs to the outside. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

lower left (Figure 10-3). The dividing lines consist of two imaginary divisions. These divisions run horizontally through the umbilicus and vertically from the **xiphoid process** through the **symphysis pubis**.

Body Cavities

The three major cavities of the human body are the thoracic cavity, the abdominal cavity, and the pelvic cavity. The thoracic cavity is divided into two portions by a midline structure known as the **mediastinum**. The mediastinum includes the trachea, esophagus, thymus, heart, and great vessels. The lungs are located on either side of this midline structure. The thoracic cavity is surrounded by the rib cage. This cavity is separated from the abdominal cavity by the diaphragm.

The thorax contains two pleural cavities (which contain the lungs) and a pericardial cavity (which contains the heart). These cavities are lined with a serous membrane. The serous membrane that comes in contact with the organ is *visceral.* The serous membrane that comes in contact with the cavity wall is *parietal.* These membranes produce a thin, lubricating film of fluid. This fluid reduces the friction that occurs during movement of organs against other organs or body cavities.

An imaginary plane divides the abdominal cavity from the pelvic cavity. The division is drawn between the symphysis pubis and the sacral promontory. The latter is the projecting portion of the pelvis at the base of the sacrum. The abdominal and pelvic cavities are lined with a thin sheet of membranous tissue. This thin sheet of tissue secretes serous fluid. The serous membrane that covers the abdominal organs is known as the **visceral peritoneum**. The serous membrane that covers the body cavity wall is known as the **parietal peritoneum**. Peritoneal organs are held in place by connective tissue called **mesentery**. The mesentery holds some of the abdominal organs to the body wall and offers a pathway for nerves and vessels to reach the organs. Abdominopelvic organs that do not have mesentery or peritoneum are said to be **retroperitoneal**. This means that they are behind the peritoneum. These organs include the kidneys, adrenal glands, pancreas, portions of the colon, and the urinary bladder. The pelvic cavity is enclosed by the bones of the pelvis. The abdominal and pelvic cavities often are referred to collectively as the *peritoneal* or *abdominopelvic cavity* (Figure 10-4).

CELL STRUCTURE

The **cell** is the basic unit of life. Cells are highly organized units composed of protoplasm, or living matter. The three main parts of all human cells are the cytoplasmic membrane **(plasma membrane)**, cytoplasm, and nucleus.

Cytoplasmic Membrane

The **cytoplasmic membrane** encloses the **cytoplasm** and forms the outer boundary of the cell. The cytoplasmic membrane is believed to have two layers of phosphate-containing fat molecules. These molecules are known as **phospholipids**. The layers form a fluid framework for the cytoplasmic membrane (Figure 10-5). Substances outside this membrane are considered **extracellular** (outside of cells) or **intercellular** (between cells). Substances inside this membrane are **intracellular**. The functions of the cytoplasmic membrane are to enclose and support the cell contents and regulate what moves into and out of the cell.

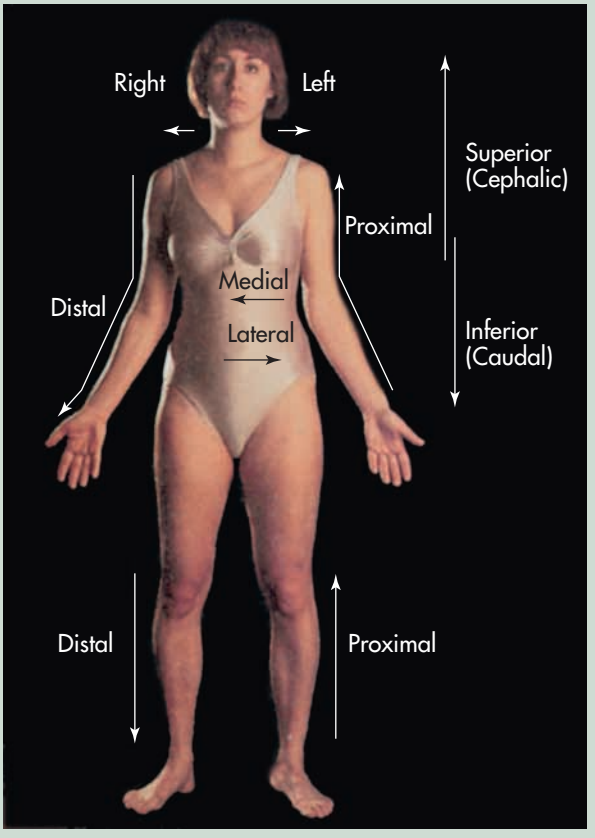
The central layer of the cytoplasmic membrane is a **lipid bilayer**. This layer is composed of a double layer of lipid molecules. The lipid bilayer has a liquid quality, and protein molecules "float" on the inner and outer surfaces. Some of these proteins have carbohydrate molecules bound to them. The protein molecules are thought to function as membrane channels, carrier molecules, receptor molecules, **enzymes**, or structural supports in the membrane (see Chapter 11).

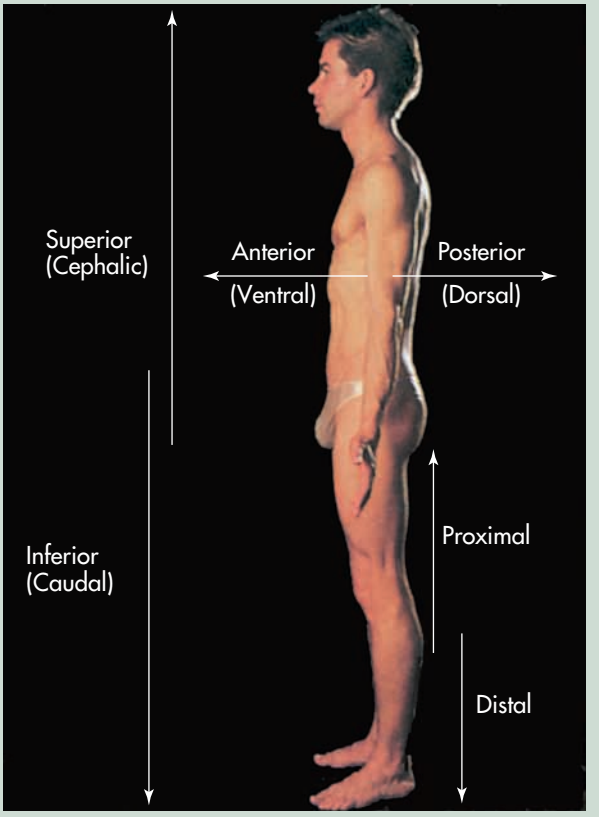
Cytoplasm

The cytoplasm lies between the cytoplasmic membrane and the nucleus. The nucleus can be viewed as a round or spherical structure in the center of the cell. Specialized structures

TABLE 10-1 Directional Terms

Term	Definition
Left	Toward the left side
Right	Toward the right side
Superior	Situated above another structure (usually synonymous with "cephalic")
Inferior	Situated below another structure (usually synonymous with "caudal")
Cephalic	Toward the head of the body
Caudal	Toward the distal end of the spine
Proximal	Closer than another structure to the point of attachment to the trunk
Distal	Farther than another structure from the point of attachment to the trunk
Medial	Toward the midline of the body
Lateral	Away from the midline of the body
Anterior	The front of the body (synonymous with "ventral")
Posterior	The back of the body (synonymous with "dorsal")
Ventral	Pertaining to the front
Dorsal	Pertaining to the back





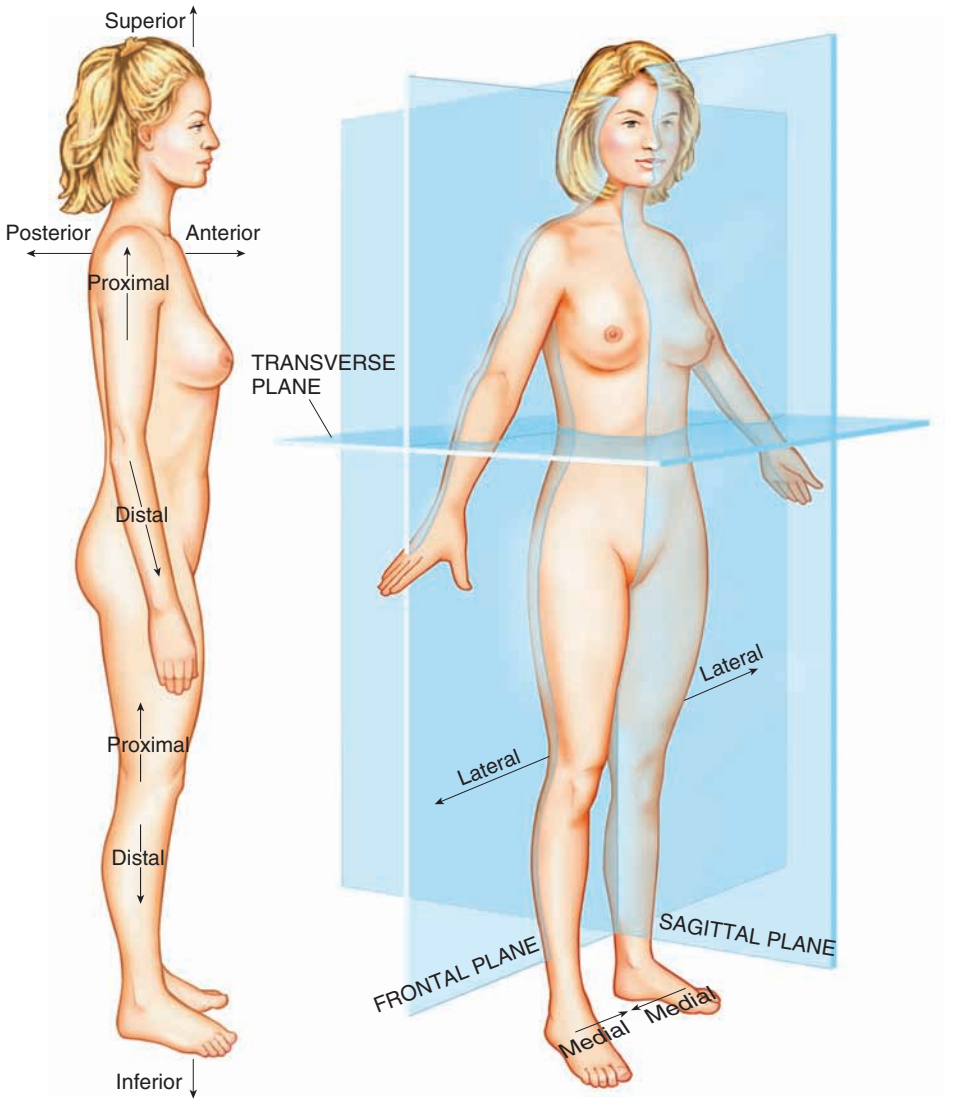


FIGURE 10-2 Body planes. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

in the cell, known as **organelles**, are located in the cytoplasm. These structures perform functions important to the cell's survival (Table 10-2 and Figure 10-6).

The **endoplasmic reticulum** is a chain of connecting sacs or canals that winds through the cytoplasm of the cell. In essence, the endoplasmic reticulum serves as a tiny circulatory system for the cell. The tubular passages or canals in the endoplasmic reticulum carry proteins and other substances through the cytoplasm of the cell from one area to another. The two types of endoplasmic reticulum are *smooth endoplasmic reticulum* and *rough endoplasmic reticulum*. Smooth endoplasmic reticulum is found in cells that handle or produce fatty substances. This organelle also plays a part in detoxification processes through the chemical action of **enzymes**. Rough endoplasmic reticulum is found in cells that produce proteins to be secreted for use outside the cell.

Ribosomes are the "factories" in the cells where protein is synthesized. Ribosomes are macromolecules of protein and **ribonucleic acid (RNA)** that are composed of thousands of atoms. Ribosomes usually are bound to the endoplasmic reticulum but also are found free in cytoplasm. Ribosomes form complexes with strands of RNA, which through the genetic code provide the blueprint for the new protein. Individual **amino acids** are attached in long chains with peptide bonds to form the new proteins.

The **Golgi apparatus** concentrates and packages materials for secretion from the cell. This organelle consists of tiny sacs composed of smooth endoplasmic reticulum. These sacs are stacked one on the other near the nucleus. The Golgi apparatus concentrates and in some cases chemically modifies the proteins. It does this by synthesizing and attaching carbohydrate molecules to the proteins to form **glycoproteins** or by attaching lipids to the proteins to

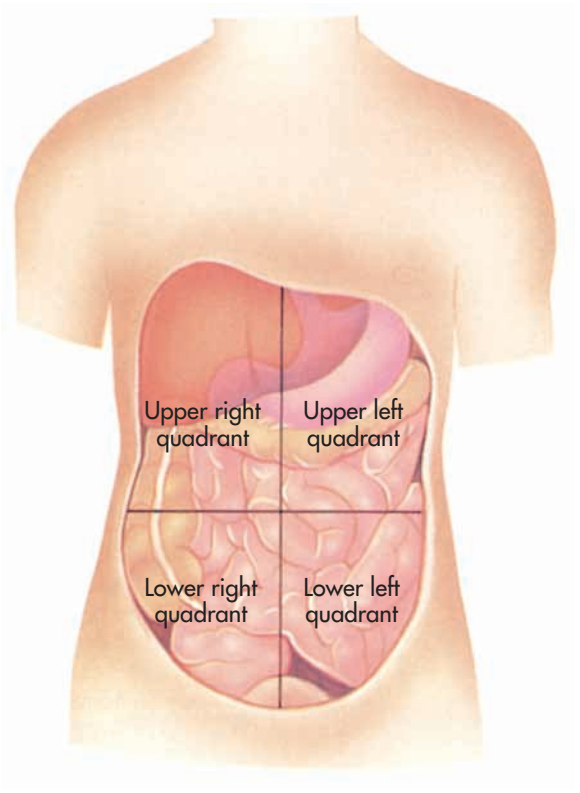

FIGURE 10-3 Abdominal quadrants.

form **lipoproteins**. These concentrated globules move slowly outward to and through the cell membrane. At this point, the globules break open and spill their contents. **Mucus** is an example of a product of the Golgi apparatus.

Lysosomes are membranous-walled organelles that contain enzymes, which enable them to function as intracellular digestive systems. These enzymes include those that digest nucleic acids, proteins, **polysaccharides**, and lipids. Certain white blood cells (leukocytes) have large numbers of lysosomes that contain enzymes to digest engulfed bacteria. If tissues are damaged, these powerful enzymes may escape from ruptured lysosome sacs into the cytoplasm, digesting damaged and healthy cells. Lysosomes also digest organelles of cells that are no longer functional **(autophagia)**.

The **mitochondria** are the "power plants" of the cell. These organelles are found throughout the cell. They are the site of **aerobic oxidation**. In the mitochondria, energy derived from the efficient **metabolism** of nutrients and oxygen via the **Krebs cycle** (further described in Chapter 11) is used to synthesize high-energy triphosphate bonds, such as **adenosine triphosphate (ATP)**. These triphosphate bonds are the energy source for the muscles, nerves, and overall function of the body.

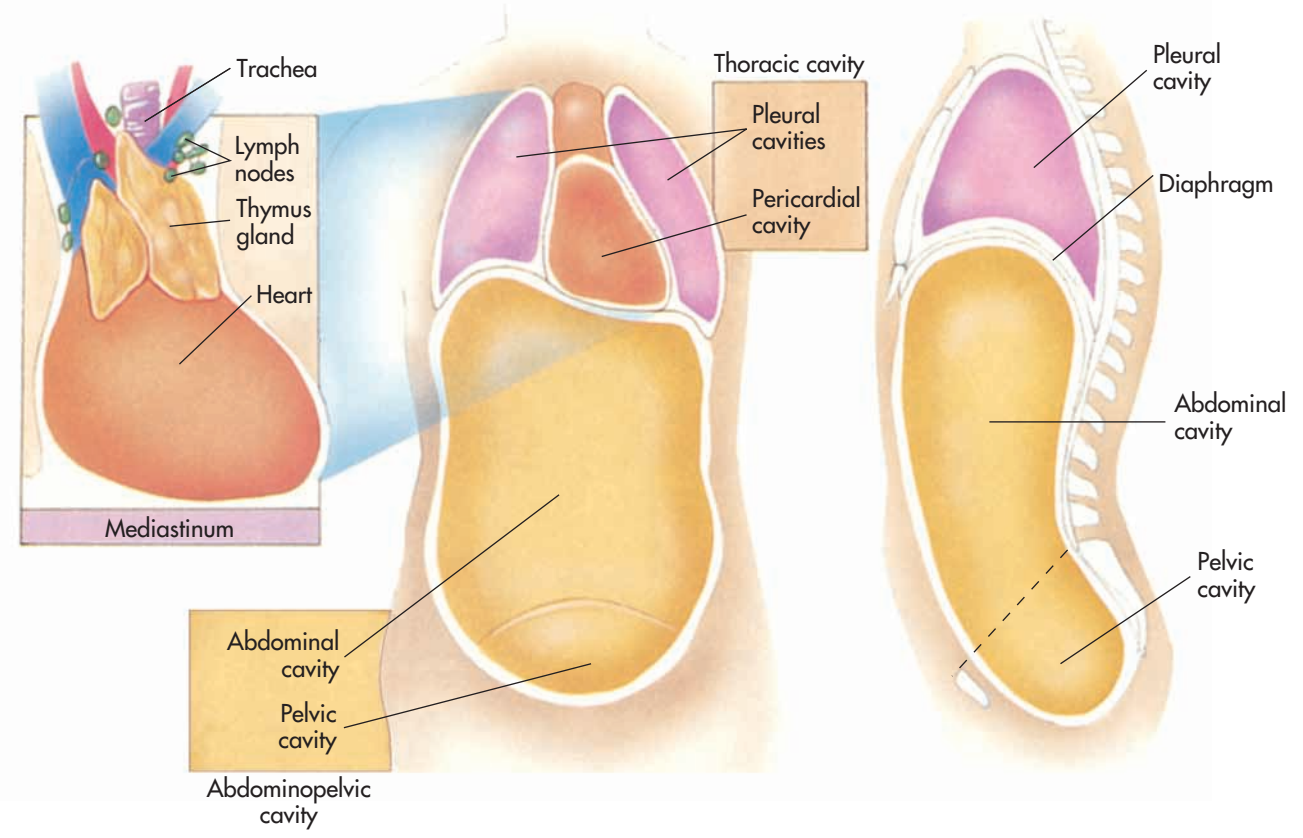

FIGURE 10-4 Body cavities. The thoracic cavity includes the two pleural cavities and the pericardial cavity. Some of the contents of the mediastinum are shown on the left. The abdominopelvic cavity contains the abdominal cavity and the pelvic cavity.

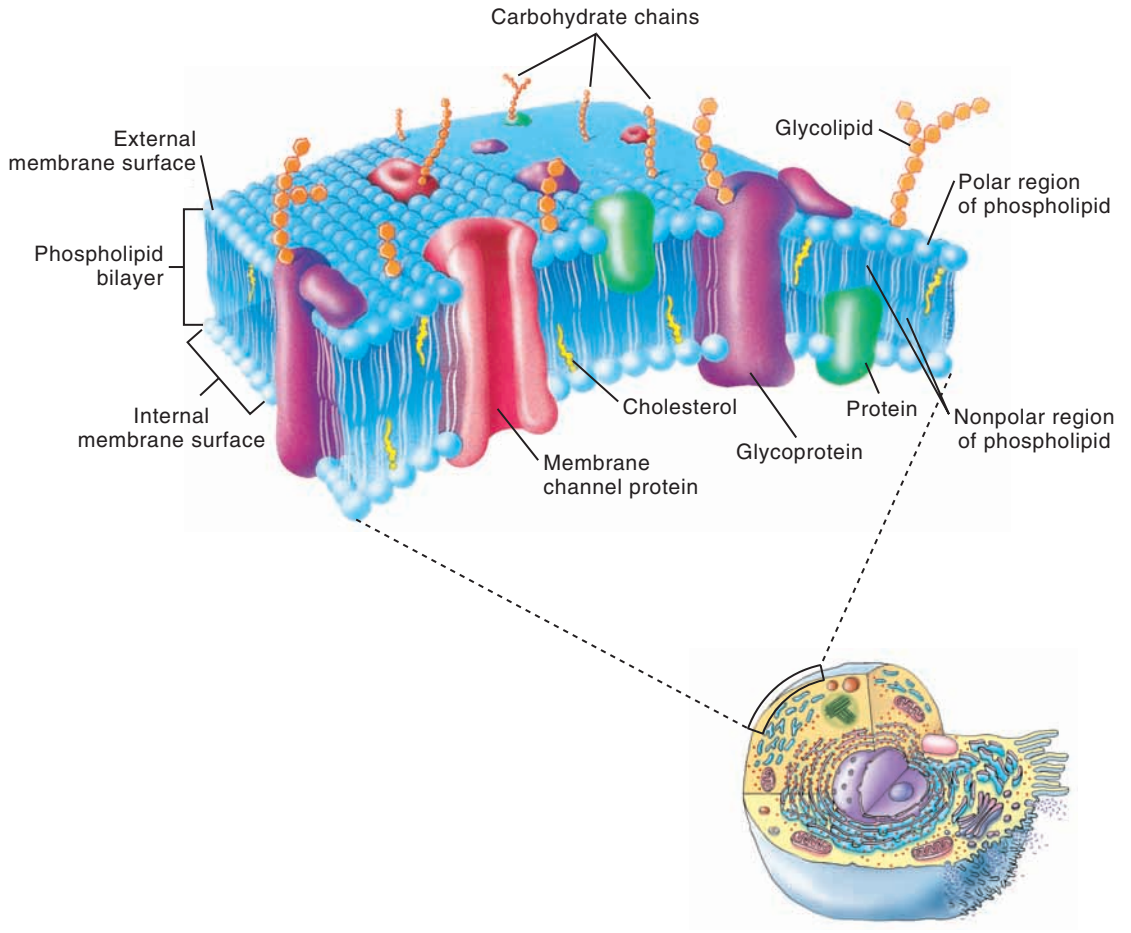

FIGURE 10-5 Fluid mosaic model of the plasma membrane. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

TABLE 10-2 Some Major Cell Structures and Their Functions

Structure	Function
Centrioles	Function in cell reproduction.
Cilia	Short, hairlike extensions on the free surfaces of some cells capable of movement.
Endoplasmic reticulum	Ribosomes attached to rough endoplasmic reticulum synthesize proteins; smooth endoplasmic reticulum synthesizes lipids and certain carbohydrates.
Flagella	Single projections of cell surfaces that are much larger than cilia; the only example in human beings is the "tail" of a sperm cell.
Golgi apparatus	Synthesizes carbohydrates, combines them with proteins, and packages the product as globules of glycoproteins.
Lysosomes	The "digestive system" of the cell.
Mitochondria	Synthesize adenosine triphosphate; the "powerhouses" of the cell.
Nucleoli	Play an essential role in the formation of ribosomes.
Nucleus	Dictates protein synthesis, thereby playing an essential role in other cell activities, namely active transport, metabolism, growth, and heredity.
Plasma membrane	Serves as the boundary of the cell. Protein and carbohydrate molecules on the outer surface of the plasma membrane perform various functions; for example, they serve as markers that identify the cells of each individual or as receptor molecules for certain hormones.
Ribosomes	Synthesize proteins; the "protein factories" of the cell.

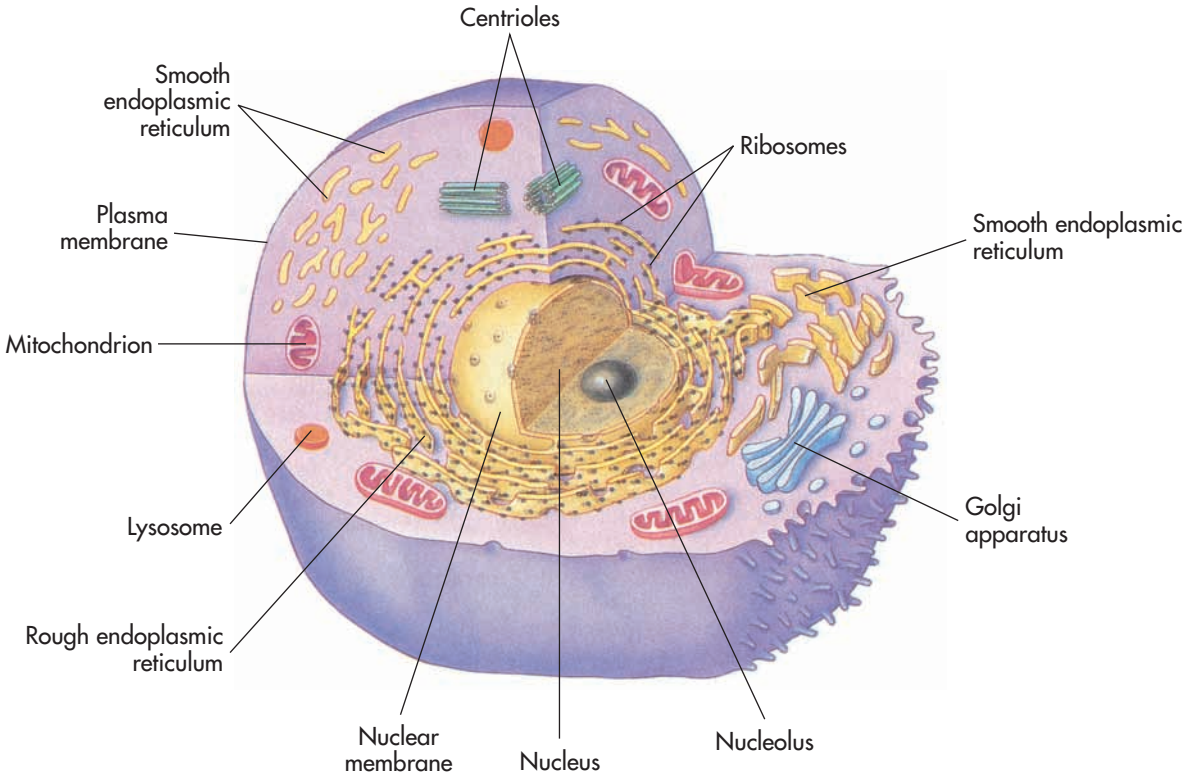

FIGURE 10-6 Artist's interpretation of cell structure. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

CRITICAL THINKING

Your patient has severe lung disease and poor oxygenation. What effect will this have on cellular energy production?

Centrioles are paired, rod-shaped organelles that lie at right angles to each other in a specialized zone of cytoplasm. This zone is known as the **centrosome**. Each centriole is composed of microtubules, which play an important role in the process of cell division. At some point in their existence, all human cells contain a nucleus in which the genetic material of the cell is located. The nucleus is a large, membrane-bound organelle that ultimately controls all other organelles in the cytoplasm. The nucleus may be spherical, elongated, or lobed, depending on the type of cell in which it is found. The nucleus usually is located near the center of the cell; however, some cells, such as red blood cells (erythrocytes), lose their nucleus as they develop. Other cells, such as certain bone cells, have more than one nucleus. The most significant categorizing feature of cells is the presence or absence of a nucleus.

Nucleus

The **nucleus** is a relatively large structure that is not always near the center of the cell. The cell nucleus is surrounded by a nuclear membrane. This membrane encloses a special type of protoplasm known as **nucleoplasm**. The nucleoplasm contains a number of specialized structures. Two of these are the nucleolus and the chromatin granules. The nucleolus consists of **deoxyribonucleic acid (DNA)**, which programs the formation of RNA, and protein, which makes ribosomes. These ribosomes then migrate through the nuclear membrane into the cytoplasm of the cell and produce proteins. **Chromatin granules** are threadlike structures made up of proteins and DNA. During cell division, the chromatin condenses to form the 23 pairs of **chromosomes** characteristic of human cells. The information in nuclear DNA determines most of the chemical events that occur within the cell. The basic functions of the nucleus are cell division and control of genetic information. Not all cells are capable of continuous division, and some cells (e.g., nerve cells) cannot reproduce.

DID YOU KNOW?

Human Genome Project

In 1990 the U.S. Human Genome Project was started through a coordinated effort by the U.S. Department of Energy and the National Institutes of Health. The project was completed in 2003. The goals of the project were the following:

- Identify all of the approximately 20,000 to 25,000 genes found in human deoxyribonucleic acid (DNA)
- Determine the sequences of the 3 billion chemical base pairs that make up human DNA
- Store this information in databases

- Improve tools for data analysis
- Transfer related technologies to the private sector
- Address the ethical, legal, and social issues (ELSI) that may arise from the project

A *genome* is all the DNA in an organism, including its genes. Genes carry information for making all the proteins required by all organisms. These proteins determine, among other things, how the organism looks, how well its body metabolizes food or fights infection, and sometimes even how it behaves.

Knowledge of the effects of DNA variations among individuals can lead to revolutionary new ways to diagnose, treat, and someday prevent the thousands of disorders that affect human beings. Besides providing clues to understanding human biology, learning about nonhuman DNA sequences or organisms can lead to an understanding of their natural capabilities. This knowledge can then be applied to solving challenges in health care, agriculture, energy production, environmental remediation, and carbon sequestration.

Modified from the US Department of Energy, Human Genome Management Information Systems (HGMIS): *About the Human Genome Project*. www.ornl.gov/sci/techresources/Human_Genome/project/about.shtml. Accessed September 11, 2010.

Major Classes of Cells

Free-living cells of multicellular "social" organisms are divided into two major classes. They are divided by the way genetic material is organized inside them. The two main types are **eukaryotes** ("true nucleus") and **prokaryotes** ("before nucleus").

Eukaryotes are larger than prokaryotes and have a more extensive intracellular anatomy. They have a separate membrane-bound nucleus. The nucleus holds the genetic material (chromosomes, DNA). The fluid filling of eukaryotes is divided into the nucleoplasm and the cytoplasm. The nucleoplasm is inside the nuclear membrane. The cytoplasm is outside the nuclear membrane. Nearly all human body cells are eukaryotes, as are those of all living organisms. Exceptions to this are bacteria, cyanobacteria (blue-green algae), and **mycoplasmas;** these are prokaryotes. **Bacteria** and mycoplasmas cause many diseases in human beings and other animals. **Viruses** have a close association with cells but are not classified as cells.

In the simpler, prokaryote cells, the genetic material and enzymes required for energy production, cell growth, and cell division are contained in the jellylike cytoplasm. The cytoplasm is surrounded by the plasma membrane. Unlike eukaryotes, these cells have a simple internal organization. Prokaryotes do not have a nucleus that is bound by a plasma membrane. Their DNA is attached to the plasma membrane.

Chief Cellular Functions

Cells have evolved in myriad ways to fulfill specific tasks in the human body. Through **differentiation** (maturation), cells become specialized in one type of function or act in concert with other cells to perform a more complex task. For example, red blood cells carry out only one function: they transport respiratory gases around the body. The cells in the pancreas synthesize and secrete large amounts of the digestive enzymes required to break down foods. The seven chief cellular functions are as follows:

1. Movement (muscle cells)
2. Conductivity (nerve cells)
3. Metabolic absorption (kidney and intestinal cells)
4. Secretion (mucous gland cells)
5. Excretion (all cells)
6. Respiration (all cells)
7. Reproduction (most cells)

Cell Reproduction

All human cells, with the exception of reproductive (sex) cells, reproduce by a process known as **mitosis**. In this process, cells divide to multiply; one cell divides to form two cells. Many cell types in the body (e.g., epithelial, liver, and bone marrow cells) undergo cell division throughout an individual's life. Other cell types (e.g., nerve and skeletal muscle cells) divide until near the time of birth.

BODY TISSUES

The characteristics of cell structure and composition are used to classify tissue types. Four main types of tissue make up the many organs of the body: epithelial tissue, connective tissue, muscle tissue, and nervous tissue.

Epithelial Tissue

Epithelial tissue covers surfaces or forms structures derived from body surfaces (e.g., glands). This tissue consists almost entirely of cells that have little or no intercellular material between them. The tissue forms continuous sheets that contain no blood vessels. Epithelium covers the outside of the body. It also lines the digestive tract, the blood vessels, and many body cavities.

CRITICAL THINKING

Think about the role of each of the tissue types. Compare these roles with the types of materials used to construct a building. How does each tissue type serve as a component for building a body?

Epithelial tissues can be subdivided by the shape and arrangement of the cells found in each type. If classified according to shape, epithelial cells are *squamous* (flat and scalelike), *cuboidal* (cube-shaped), or *columnar* (more tall than wide). If classified according to arrangement, epithelial cells are *simple* (a single layer of cells of the same shape), *stratified* (multiple layers of cells of the same shape), or *transitional* (several layers of cells of differing shapes).

Connective Tissue

Connective tissue is the most abundant type of tissue in the body. Connective tissue is also the most widely distributed type. It consists of cells separated from each other by intercellular material. This material is known as the

extracellular matrix. This nonliving matrix gives most connective tissue its fundamental characteristics and is the basis for separating connective tissue into the following seven subgroups.

1. **Areolar connective tissue** is a loose tissue. It consists of delicate webs of fibers and a variety of cells embedded in a matrix of soft, sticky gel. Areolar connective tissue is the "loose packing" material of most organs and other tissues. It attaches the skin to the underlying tissues. The areolar connective tissue contains three major types of protein fibers: collagen, reticulum, and elastin.
2. **Adipose tissue** (fat tissue) is a specialized connective tissue that stores lipids. Lipids take up less space per calorie than carbohydrates or proteins. This tissue, therefore, not only acts as an insulator and protector but also as a site of energy storage.
3. **Fibrous connective tissue** is made up mainly of bundles of strong, white collagenous fibers in parallel rows. Tendons are composed of this type of connective tissue. Fibrous connective tissue is characterized by strength and inelasticity.
4. **Cartilage** is made up of cartilage cells (chondrocytes). These cells are located in tiny spaces and are distributed throughout a somewhat rigid matrix. The makeup of cartilage varies by its location and ultimate role. For example, *hyaline cartilage* is found at articulating surfaces and is firm and smooth. *Fibrocartilage* is more flexible and supple. Cartilage makes up part of the human skeleton and covers the articulating surfaces of bones. In addition, cartilage forms the major skeletal tissue of the embryo before it is replaced by bony tissue. The type of cartilage depends on the relative amounts of collagen, elastin, and ground substance. Ground substance is composed of nonfibrous protein and other organic molecules and fluid. Increased amounts of collagen or elastin allow cartilage to spring back after being compressed. Because blood vessels do not penetrate the substance of cartilage, cartilage heals slowly after injury.
5. **Bone** is a highly specialized form of hard, connective tissue. It consists of living cells and mineralized matrix. The strength and rigidity of this matrix allow bone to support and protect other tissues and organs. Bones are classified according to their shape. **Long bones**, for example, are longer than they are wide (Figure 10-7). The humerus, ulna, radius, femur, tibia, fibula, and phalanges are long bones. **Short bones** are about as broad as they are long. Examples of short bones are the carpal bones of the wrist and the tarsal bones of the ankle. **Flat bones** have a thin, flattened shape. Examples of flat bones are certain skull bones, the ribs, sternum, and scapulae. **Irregular bones** are bones that do not fit any of the other three categories. Examples of irregular bones include vertebrae and facial bones.

   Each growing long bone consists of a **diaphysis** (shaft), an *epiphysis* at the end of each bone, and an **epiphyseal plate** (growth plate). The epiphyseal plate is the site of bone elongation. When bone growth stops, the epiphyseal plate becomes ossified. The plate then is called the *epiphyseal line*. An injury to this area can impair bone growth if it is not recognized and treated properly (see Chapter 44).

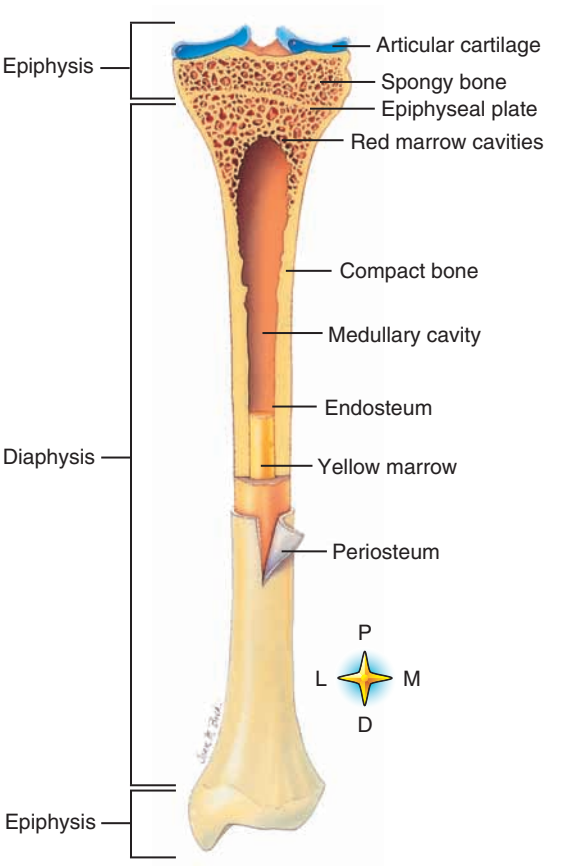

FIGURE 10-7 Long bone. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

CRITICAL THINKING

Intraosseous infusion is a critical intervention that can save a life. It is used to administer fluids and drugs. This infusion requires the insertion of a needle into the humerus or bone of the leg. Why could failure to identify anatomical landmarks or to place the needle correctly in the epiphysis in a child be harmful?

Bones contain large cavities and smaller cavities. An example of a large cavity is the medullary cavity in the diaphysis. Smaller cavities include the epiphyses of long bones and throughout the interior of other bones. These spaces are filled with **yellow marrow** (mainly adipose tissue) or **red marrow** (the site of blood formation). Blood supply to most bones is excellent. Therefore, some bones, such as the tibia and sternum, are suitable choices for venous access by means of intraosseous infusion (described in Chapter 14).

Bones can be classified further as cancellous or spongy bone and compact bone. **Cancellous bone** has spaces between the plates of the bone and resembles a sponge. **Compact bone** is essentially solid. Unlike cartilage, bone has a rich blood supply and can repair itself much more readily than cartilage.

6. **Blood** is a unique connective tissue because the matrix between the cells is liquid. The liquid matrix of blood allows it to flow rapidly through the body. Blood carries nutrients, oxygen, waste products, and other materials.
7. **Hematopoietic tissue** is the connective tissue in the marrow cavities of bones. This tissue also is in organs such as the spleen, tonsils, and lymph nodes. This tissue is responsible for the formation of blood cells and cells of the lymphatic system that are important in the defense against disease.

Muscle Tissue

Muscle tissue is a contractile tissue and is the force behind all body movement. It is highly specialized to contract or shorten forcefully. Muscle tissue is classified as skeletal, cardiac, and smooth (visceral) muscle, according to the anatomical location and function. When classified by appearance, muscle is *striated* or *nonstriated*. When classified by function, muscle is *voluntary* (consciously controlled) or *involuntary* (not normally consciously controlled). The three types of muscles are *striated voluntary* (skeletal) muscle, *striated involuntary* (cardiac) muscle, and *nonstriated involuntary* (smooth) muscle.

Skeletal muscle attaches to bones. It represents a large portion of the total weight of the human body. Contraction of these muscles is responsible for body movement. **Cardiac muscle** is the muscle of the heart. Contraction of the cardiac muscle pumps blood throughout the body. **Smooth muscle** is widespread throughout the body and is responsible for a variety of functions. Examples include movement in the digestive, urinary, and reproductive systems.

Nervous Tissue

Nervous tissue is characterized by its ability to conduct electrical signals, which are known as **action potentials**. Nervous tissue consists of two basic kinds of cells: neurons and neuroglia.

Neurons, or nerve cells, are the actual conducting cells of nervous tissue. They are composed of three major parts: cell body, dendrite, and axon. The cell body contains the nucleus and is the site of general cell functions. Dendrites and axons are nerve cell processes (projections of cytoplasm surrounded by membrane). Dendrites receive electrical impulses and conduct them toward the cell body. Axons usually conduct impulses away from the cell body. Neurons take many different sizes and shapes, especially in the brain and spinal cord.

Neuroglia are the support cells of the brain, spinal cord, and peripheral nerves. These cells are divided into several subgroups that nourish, protect, and insulate neurons.

ORGAN SYSTEMS

An **organ** is a structure made up of two or more kinds of tissues that are organized to perform a more complex job than any one tissue can perform. A **system** is a group of organs arranged to perform a more complex job than any one organ can perform (Figure 10-8). The human body has 11 major organ systems[3]:

1. Integumentary system
2. Skeletal system
3. Muscular system
4. Nervous system
5. Endocrine system
6. Circulatory system
7. Lymphatic system
8. Respiratory system
9. Digestive system
10. Urinary system
11. Reproductive system

Integumentary System

The **integumentary system** is the largest organ system of the body. It consists of the skin and accessory structures such as hair, nails, and a variety of glands. The functions of this system include protecting the body against injury and dehydration. The integumentary system also defends against invading microorganisms and regulates temperature.

CRITICAL THINKING

Consider your knowledge of the functions of the skin. What signs, symptoms, or complications would you expect in a patient with burns covering half the body?

SKIN

The skin is a sheetlike organ composed of two distinct layers of tissue, the epidermis and the dermis (Figure 10-9). The **epidermis** is the outermost layer of the skin. It consists of tightly packed epithelial cells. Cells of the innermost layer of the epidermis can undergo mitosis and can repair themselves if injured. Because of this characteristic, the body can maintain an effective barrier against infection, even when subjected to injury and normal wear and tear.

The **dermis** is the deeper of the two layers of the skin. The dermis is largely made up of connective tissue. It is much thicker than the epidermis and contains collagenous and elastic fibers. The dermis also contains a specialized network of nerves and nerve endings. These nerves provide sensory information about pain, pressure, touch, and temperature. At various levels of the dermis are muscle fibers, hair follicles, sweat and sebaceous glands, and many blood vessels.

The layers of the skin are supported by a thick layer of loose connective tissue and fat. This is known as **subcutaneous tissue**. Subcutaneous tissue insulates the body from temperature extremes. It serves as a source of stored energy

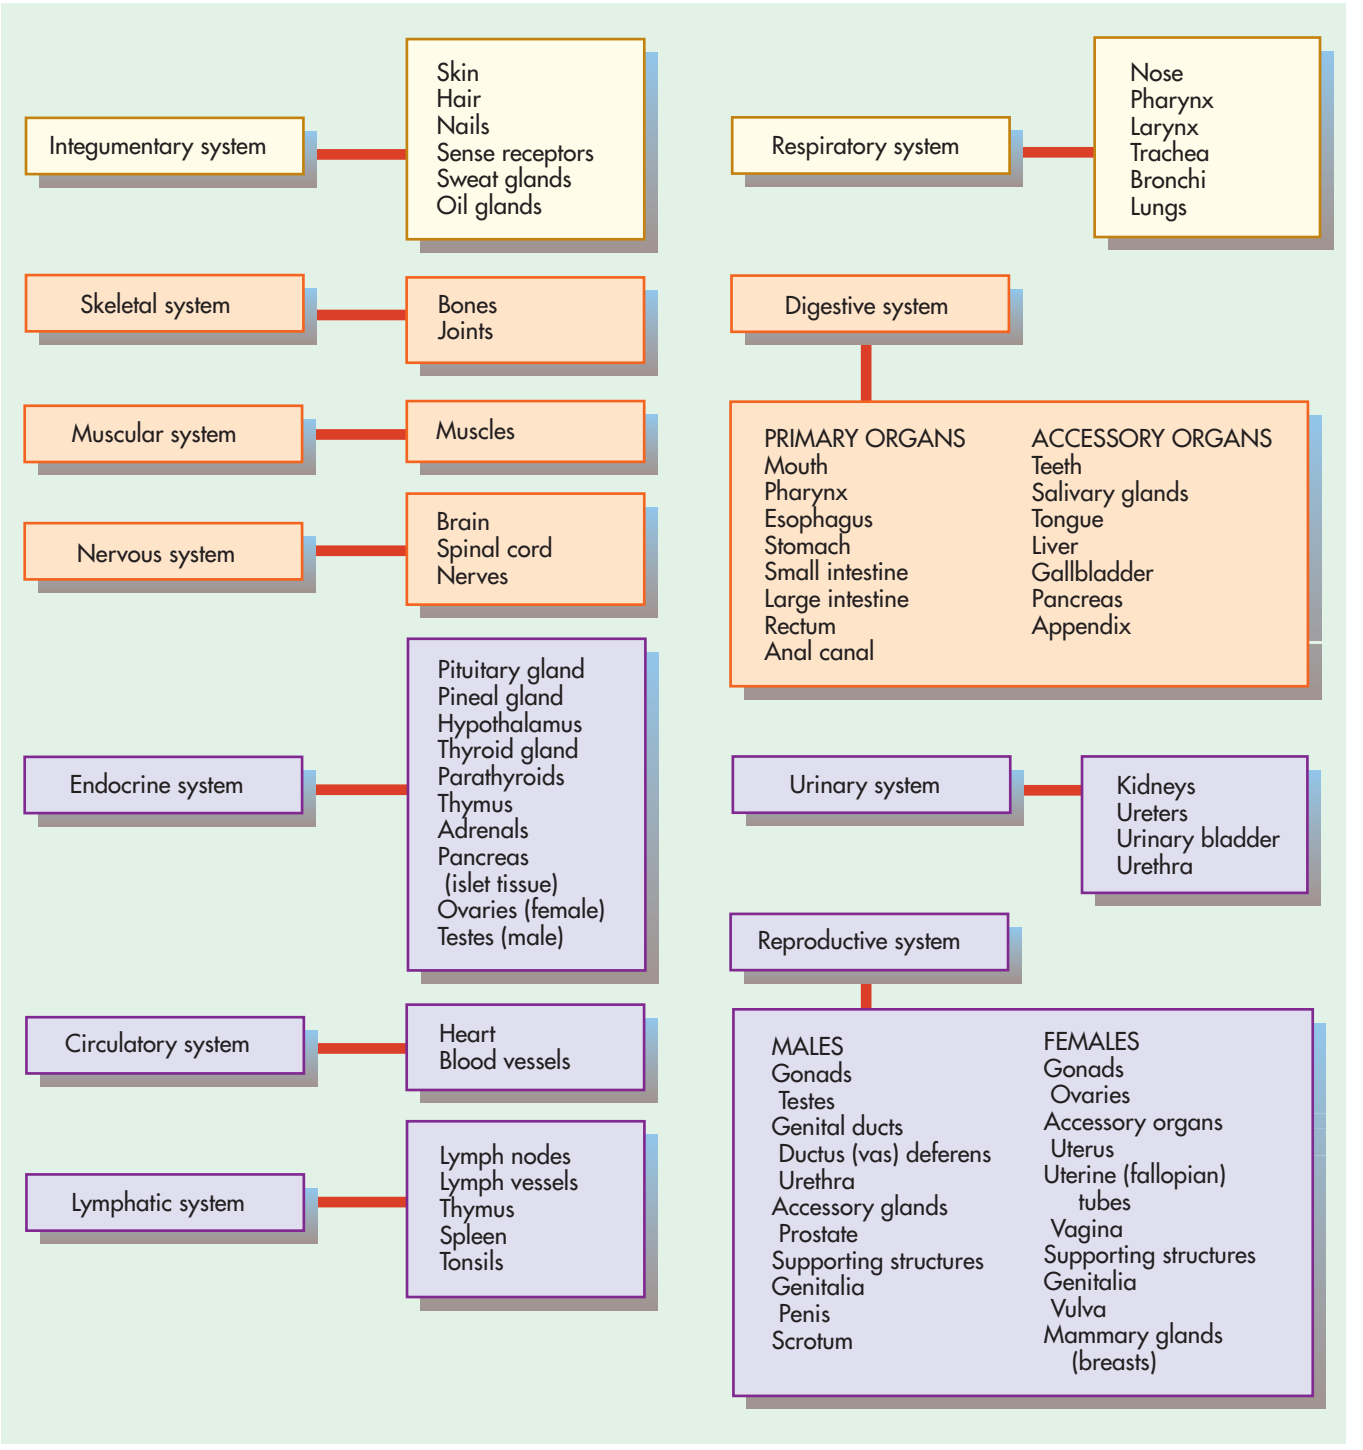

FIGURE 10-8 Body systems and their organs.

and acts as a shock absorber to protect underlying tissue from injury.

HAIR

Hair growth begins when cells of the epidermal layer of the skin grow into the dermis, forming a small tube called the *hair follicle*. Hair growth begins from a small, cap-shaped cluster of cells called the *hair papilla*. The part of the hair that lies hidden in the follicle is known as the *root,* and the visible part is called the *shaft*. Smooth muscles known as *arrector pili* are associated with each hair follicle. Movement of the hair follicle by the arrector pili produces pressure on the skin (resulting in "goose bumps") and pulls the hairs upward.

NAILS

Nails are produced by cells in the epidermis. The visible part of the nail is the *nail body*. The root of the nail lies in a

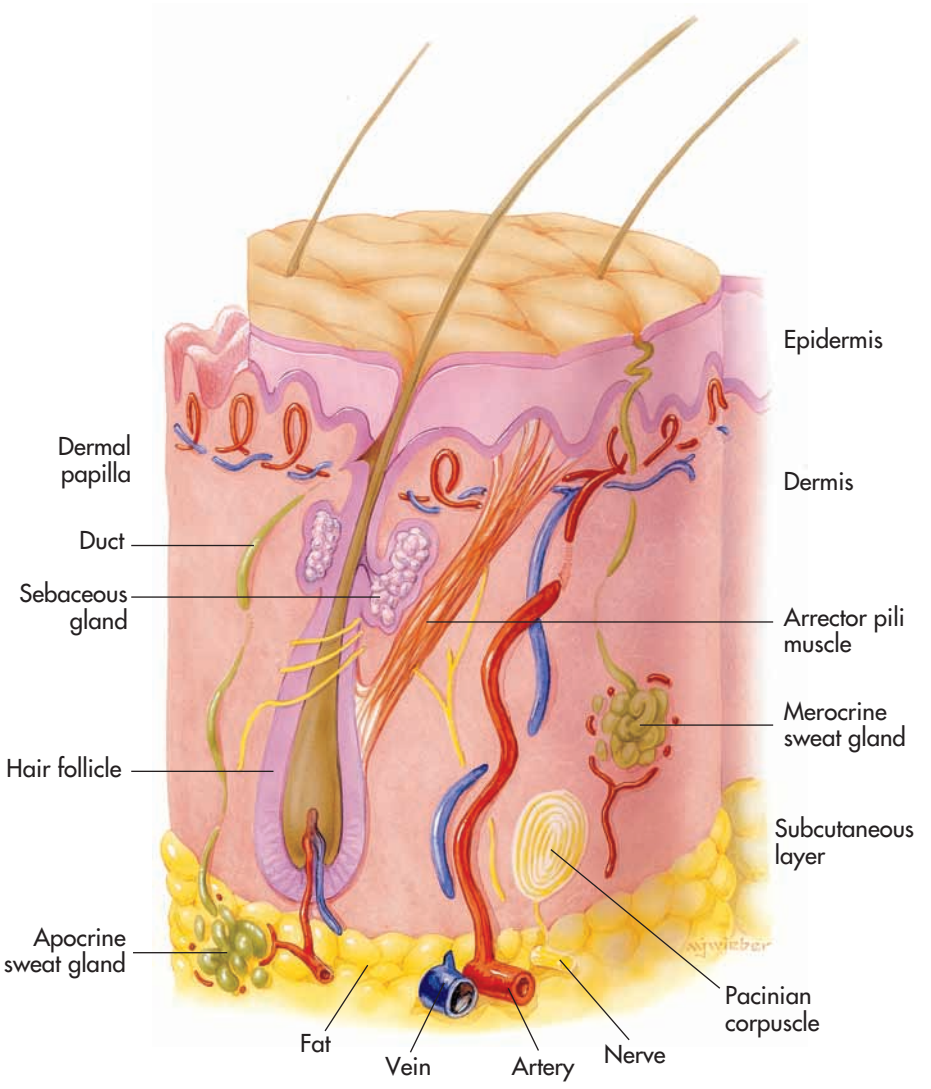

FIGURE 10-9 Microscopic view of the skin.

groove and is hidden by a fold of skin known as the *cuticle*. The crescent-shaped white area of the nail is called the *lunula* and is most visible on the thumbnail. The nail bed that lies under the nail contains many blood vessels. In healthy individuals, this layer of epithelium appears pink through the translucent nail body.

GLANDS

The major glands of the skin are the sebaceous and sweat glands. Most **sebaceous glands** are found in the dermis and secrete oil **(sebum)** for the hair and skin. This oil prevents drying and protects against some bacteria. Sebum secretion increases during adolescence, stimulated by increased blood levels of the sex hormones. Other skin glands include the *ceruminous glands* of the external auditory meatus, which produce cerumen (earwax), and the *mammary glands*.

Sweat glands (sudoriferous glands) are the most numerous skin glands. They usually are classified as merocrine or apocrine, according to their mode of secretion. *Merocrine sweat glands* are the most common. They open directly onto the surface of the skin through sweat pores. The coiled portion of the gland produces a fluid that is mostly water but also contains some salts (mainly sodium chloride) and small amounts of ammonia, urea, uric acid, and lactic acid. As the body temperature rises, the sweat glands produce sweat. The sweat evaporates and cools the body. *Apocrine glands* usually open into hair follicles. These glands are found in the axillae and genitalia and around the anus. These glands become active at puberty through the influence of sex hormones. Apocrine glands secrete an organic substance that is odorless when released but is quickly metabolized by bacteria to cause body odor.

CRITICAL THINKING

The ability to sweat is impaired in the elderly. What implications does this have?

Skeletal System

The skeletal system consists of bones and associated connective tissues. These tissues include cartilage, tendons, and ligaments. The skeletal system offers a rigid framework for support and protection. It also provides a system of levers on which muscles act to produce body movements. The skeletal system contains 206 bones. Bones are divided into two groups, the axial skeleton and the appendicular skeleton (Figure 10-10).

AXIAL SKELETON

The **axial skeleton** is made up of the skull, hyoid bone, vertebral column, and thoracic cage. The skull is composed of 28 bones. These bones are divided into three groups: the auditory ossicles, the cranial vault, and the facial bones (Figure 10-11). The six auditory ossicles (three on each side of the head) are located inside the cavity of the temporal bone. The auditory ossicles function in hearing.

The **cranial vault** consists of six bones that surround and protect the brain. They are the *parietal*, *temporal*, *frontal*, *occipital*, *sphenoid*, and *ethmoid* bones.

The 14 facial bones form the structure of the face in the anterior skull. However, these bones do not contribute to the cranial vault. They include the *maxilla*, *mandible*, and *zygomatic*, *palatine*, *nasal*, *lacrimal*, *vomer*, and *inferior nasal concha* bones. The frontal and ethmoid bones contribute to the cranial vault and the face.

The **hyoid bone** is attached to the skull by muscles and ligaments and "floats" in the superior aspect of the neck, just below the mandible. The hyoid bone serves as the attachment point for several important neck and tongue muscles.

The vertebral column consists of 33 bones, which can be divided into five regions: 7 cervical vertebrae, 12 thoracic vertebrae, 5 lumbar vertebrae, 5 sacral vertebrae (fused), and 4 coccygeal vertebrae (fused) (Figure 10-12).

The weight-bearing portion of a vertebra is a bony disk called the *body*. Intervertebral disks are located between the bodies of adjacent vertebrae. The disks serve as shock absorbers for the vertebral column. They also provide additional support for the body. In addition, the disks prevent the vertebral bodies from rubbing against each other. The spinal cord is protected by the vertebral arch and the dorsal portion of the body. A *transverse process* extends laterally from each side of the arch, and a single *spinous process* is present at the point of junction. Much vertebral movement is accomplished by the contraction of skeletal muscles attached to the transverse and spinous processes.

The thoracic cage protects vital organs in the thorax. It also prevents the thorax from collapsing during respiration. The thoracic cage consists of the thoracic vertebrae, ribs with their associated **costal cartilages**, and the **sternum** (Figure 10-13).

The 12 pairs of ribs can be divided into *true ribs* or *false ribs*. The superior seven ribs (the true ribs) articulate with the thoracic vertebrae and attach directly through their costal cartilages to the sternum. The inferior five ribs (the false ribs) articulate with the thoracic vertebrae but do not attach directly to the sternum. The eighth, ninth, and tenth ribs are joined to a common cartilage, which is attached to the sternum. The eleventh and twelfth ribs are "floating" ribs that have no attachment to the sternum.

The sternum is divided into three parts: the manubrium, the body, and the xiphoid process. At the superior margin of the manubrium is the **jugular notch** (also known as the *suprasternal notch*). This notch can be easily palpated at the anterior base of the neck. The point where the manubrium joins the body of the sternum is the **sternal angle** (also known as the *angle of Louis*). The second rib is found lateral to the sternal angle and is used clinically as a starting point for counting the other ribs.

APPENDICULAR SKELETON

The **appendicular skeleton** consists of the bones of the upper and lower extremities. It also consists of their girdles, by which they are attached to the body.

The scapula and clavicle form the pectoral girdle. This girdle attaches the upper limbs to the axial skeleton. The direct point of attachment between the bones of the appendicular and axial skeletons occurs at the **sternoclavicular joint** between the clavicle and the sternum.

The **humerus** is the second longest bone in the body. The head of the humerus articulates with the scapula. The *greater and lesser tubercles* are on the lateral and anterior surfaces of the proximal end of the humerus. There the tubercles act as sites of muscle attachments. The humerus articulates with the **radius** and **ulna** at its distal end. The *capitulum* (lateral aspect of the humerus) articulates with the head of the radius. The *trochlea* (medial aspect of the humerus) articulates with the ulna. Proximal to the trochlea and capitulum are the *medial* and *lateral epicondyles*, respectively. These sites act as muscle attachments for the muscles of the forearm. Figure 10-14 illustrates the bones of the upper extremity.

The large bony process of the ulna (the *olecranon process*) can be felt at the point of the elbow. This process fits into a large depression on the posterior surface of the humerus known as the *olecranon fossa*. The structural relationship between these two processes makes movement of the joint possible. The distal end of the ulna has a small head that articulates with the radius and wrist bones. The posterior-medial side of this head has a small *styloid process* to which the ligaments of the wrist are attached. The proximal end of the radius articulates with the humerus. The medial surface of the head constitutes a smooth cylinder where the radius rotates against the radial notch of the ulna. Major anterior arm muscles (biceps brachii) are attached to the *radial tuberosity*.

The wrist is composed of eight carpal bones, which are arranged in two rows of four each. Five **metacarpals** are attached to the **carpal bones** and constitute the bony framework of the hand. Twenty-eight **phalanges** make up

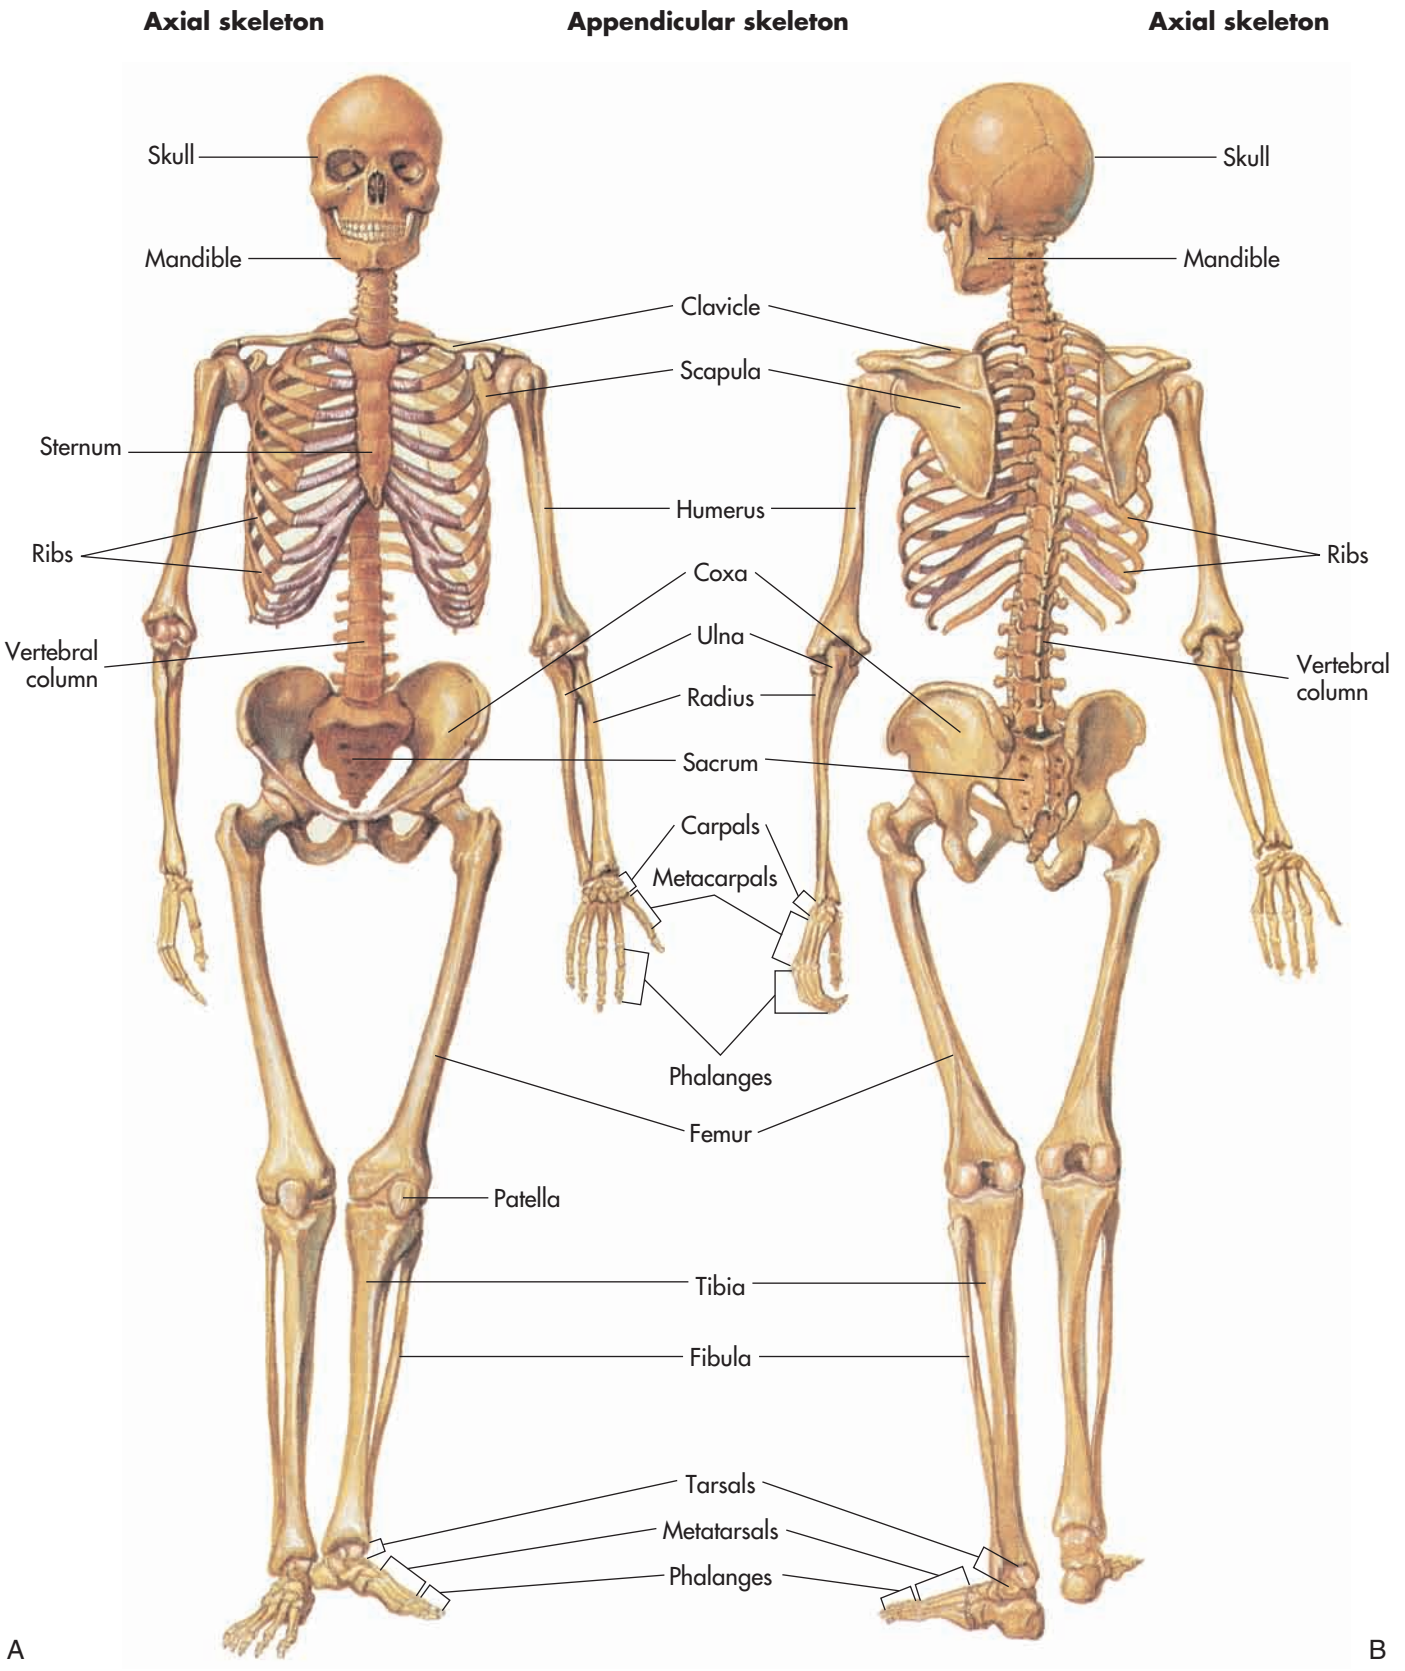

FIGURE 10-10 Anterior view **(A)** and posterior view **(B)** of the skeleton.

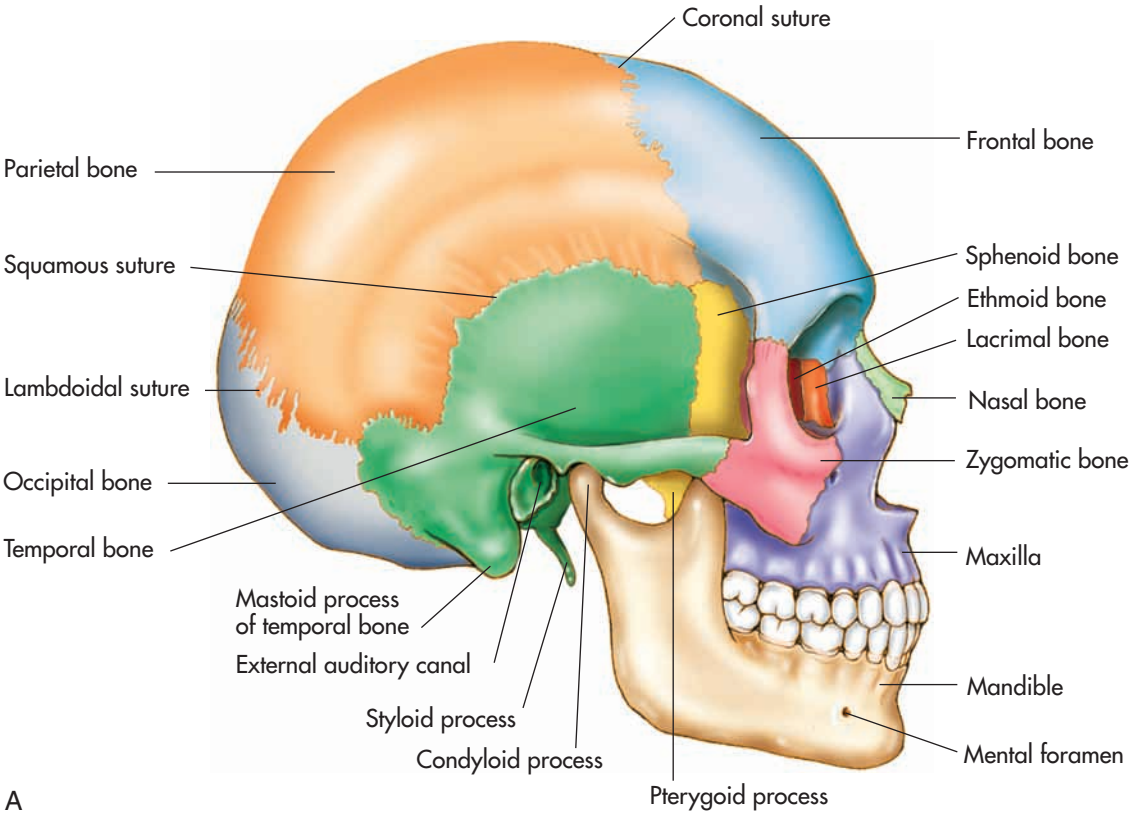

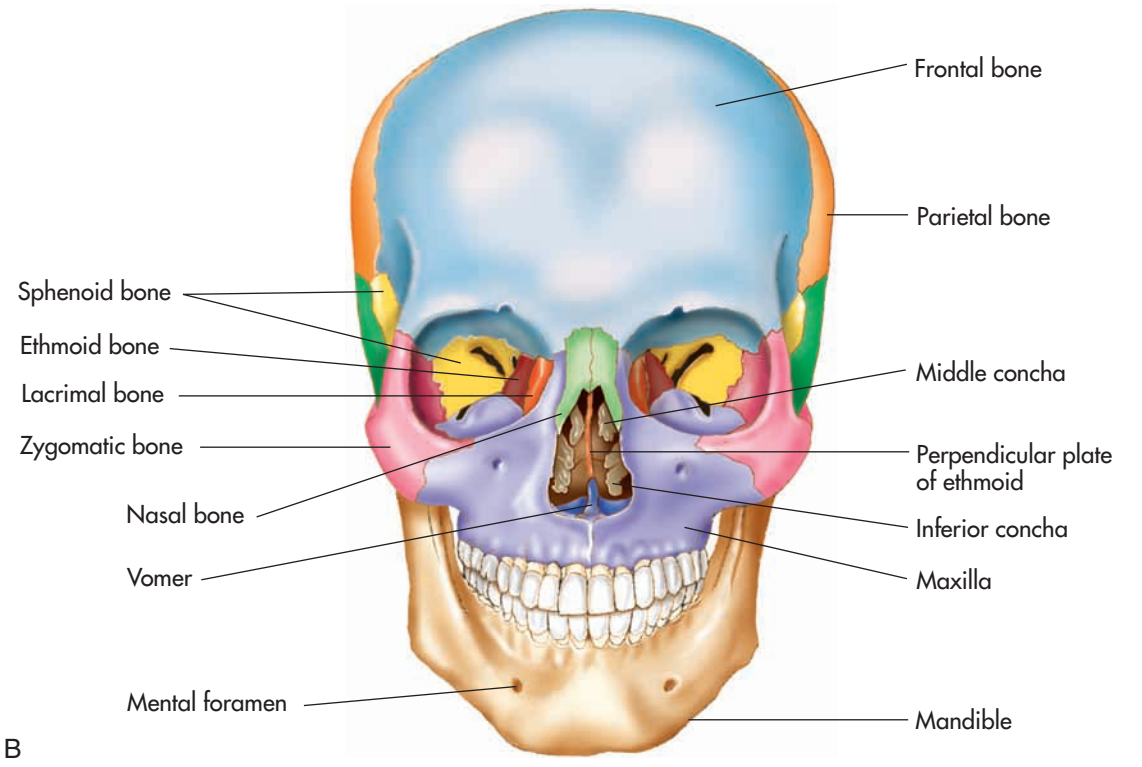

FIGURE 10-11 Skull viewed from the right side **(A)** and the front **(B)**.

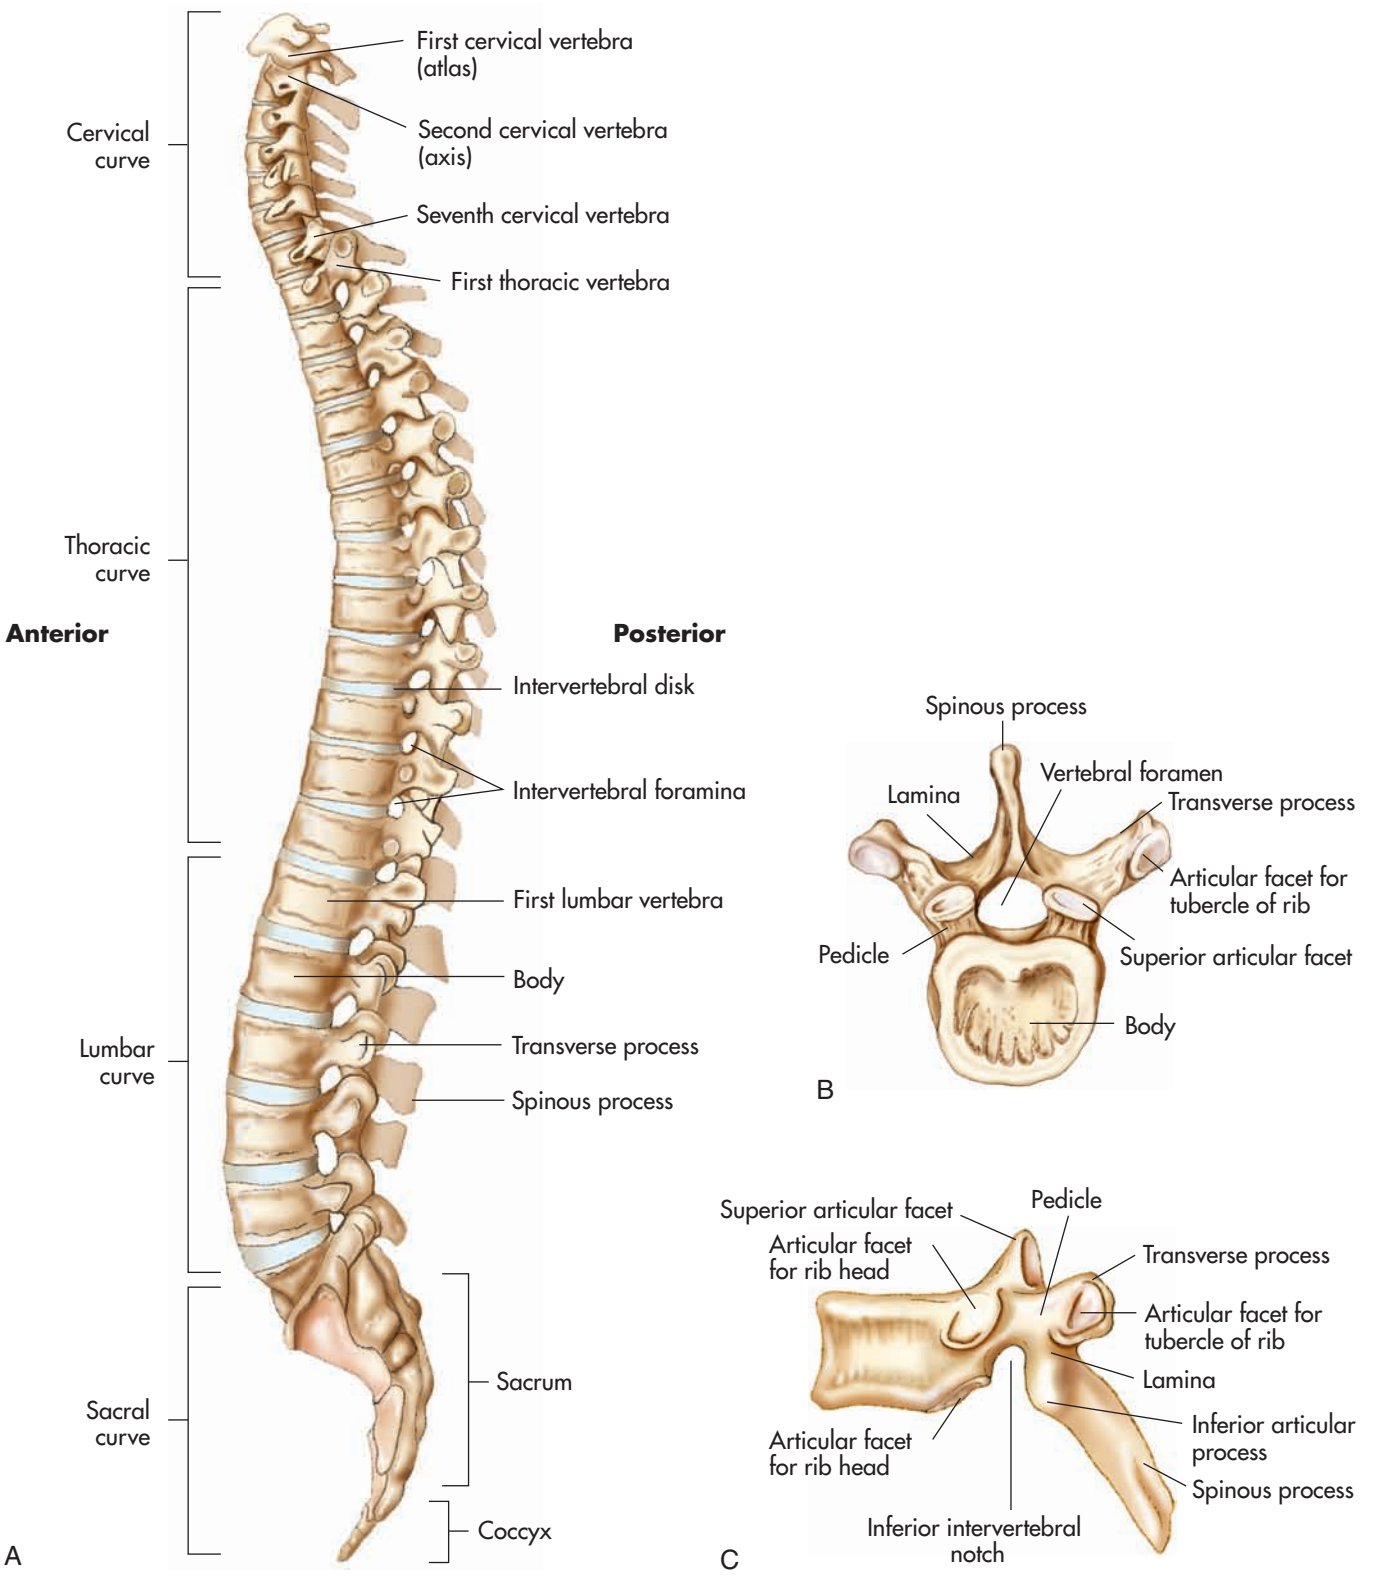

FIGURE 10-12 **A,** Vertebral column viewed from the left side. **B,** Superior view of the vertebrae. **C,** Lateral view of the vertebrae.

the 10 digits of the hands. Each thumb has two phalanges, and each finger has three phalanges.

The pelvic girdle attaches the legs to the trunk (Figure 10-15). The girdle consists of two **coxae** (hip bones). One is located on each side of the pelvis. Each coxa surrounds a large **obturator foramen**, through which muscles, nerves, and blood vessels pass to the leg. A fossa called the **acetabulum** is located on the lateral surface of each coxa. The acetabulum is the point of articulation of the lower limb with the girdle. During development, each coxa is formed by the fusion of three separate bones: the **ilium**, the **ischium**, and the **pubis**. The superior portion of the ilium is the **iliac crest**. The crest ends anteriorly as the anterior-superior iliac spine and posteriorly as the posterior-superior iliac spine.

The **femur** is the longest bone in the body. The femur has a neck that is well defined. It also has a prominent rounded head that articulates with the acetabulum. The proximal shaft has two tuberosities: a *greater trochanter,* which is lateral to the neck, and a smaller or *lesser trochanter,* which is inferior and posterior to the neck. Both trochanters are attachment sites for muscles that attach the hip to the thigh. The distal end of the femur has *medial* and *lateral condyles* that articulate with the tibia. Located laterally and proximally to the condyles are the *medial* and *lateral epicondyles*. These are sites of muscle and ligament attachment. Figure 10-16 illustrates the bones of the lower extremity.

CRITICAL THINKING

Why should you anticipate blood loss when large bones are fractured?

Distally, the femur also articulates with the **patella**, which is located in a major tendon of the thigh muscle. The patella allows the tendon to turn the corner over the knee.

The two bones of the leg are the tibia and the fibula. The **tibia** is the larger of the two and supports most of the weight of the leg. A *tibial tuberosity* can be seen and palpated just inferior to the patella. The proximal end of the tibia has *flat medial* and *lateral condyles* that articulate with the condyles of the femur. The distal end of the tibia forms the **medial malleolus**, which helps to form the medial side of the ankle joint.

The **fibula** does not articulate with the femur. However, the fibula does have a small proximal head that articulates with the tibia. The distal end of the fibula forms the lateral malleolus to create the lateral aspect of the ankle joint.

The foot consists of seven **tarsal bones** (Figure 10-17). The talus articulates with the tibia and the fibula to form the ankle joint. The **calcaneus** is located inferior and just lateral to the talus, supporting the bone. The calcaneus protrudes posteriorly where the calf muscles attach to it. The calcaneus is identified easily as the heel. The foot consists of tarsals, **metatarsals**, and phalanges. These bones are arranged in a manner similar to the metacarpals and phalanges of the hand, the great toe being analogous to the thumb. The ball of the foot is the junction between the metatarsals and the phalanges. Strong ligaments and leg muscle tendons normally hold the foot bones firmly in their arched position.

BIOMECHANICS OF BODY MOVEMENT

With the exception of the hyoid bone, every bone in the body connects to at least one other bone.

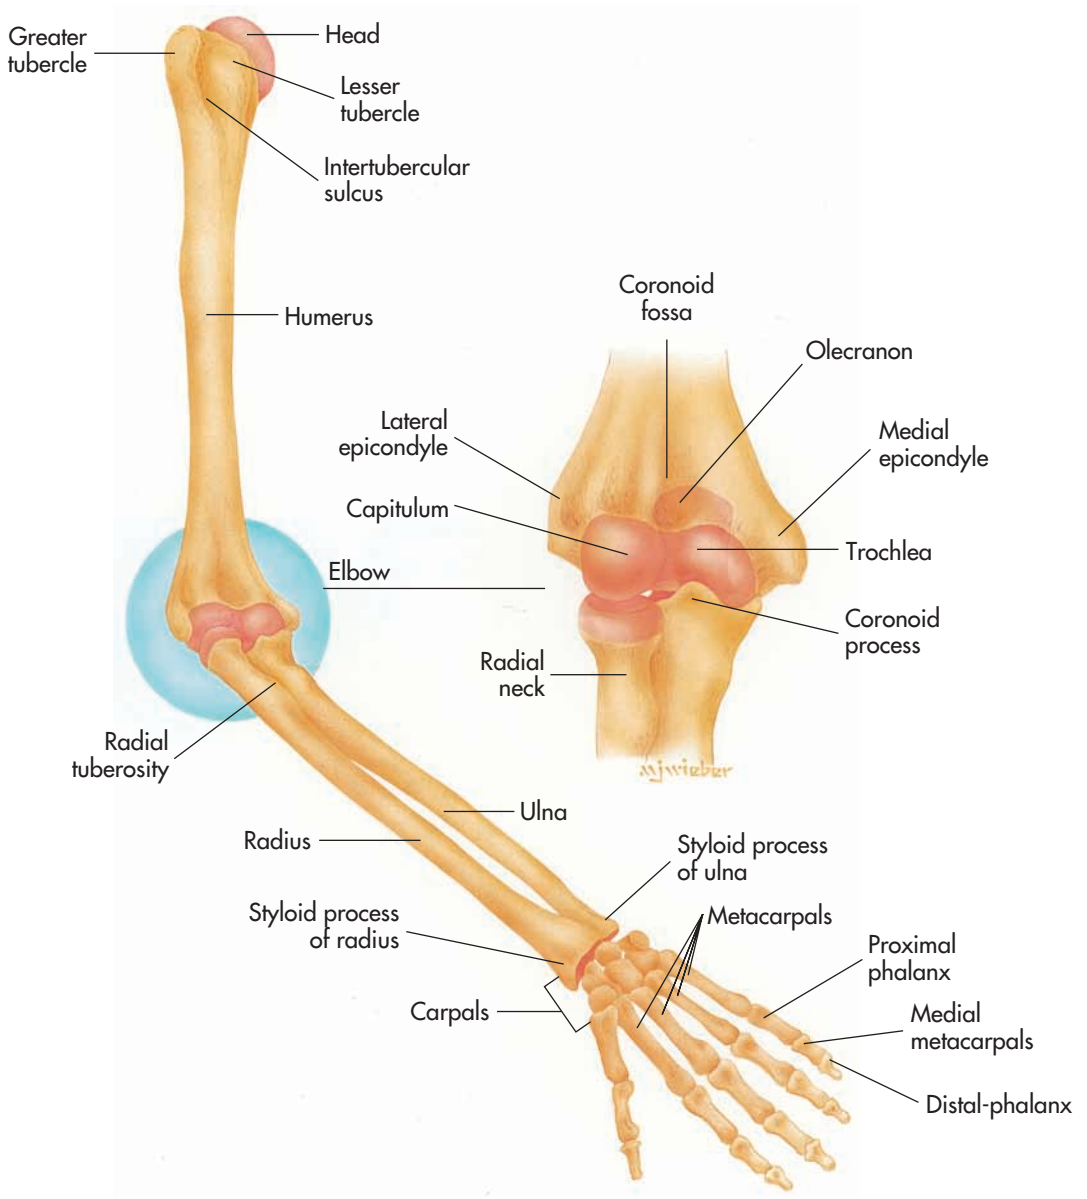

FIGURE 10-14 Bones of the upper extremity.

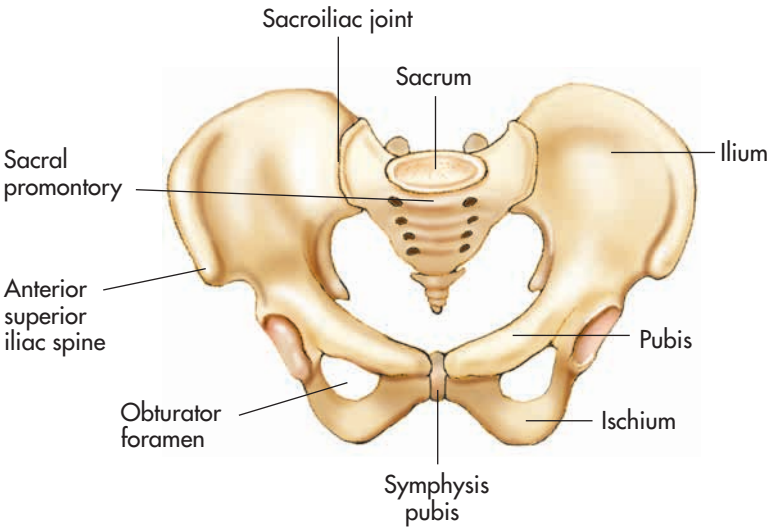

FIGURE 10-15 Complete pelvic girdle (anterior view).

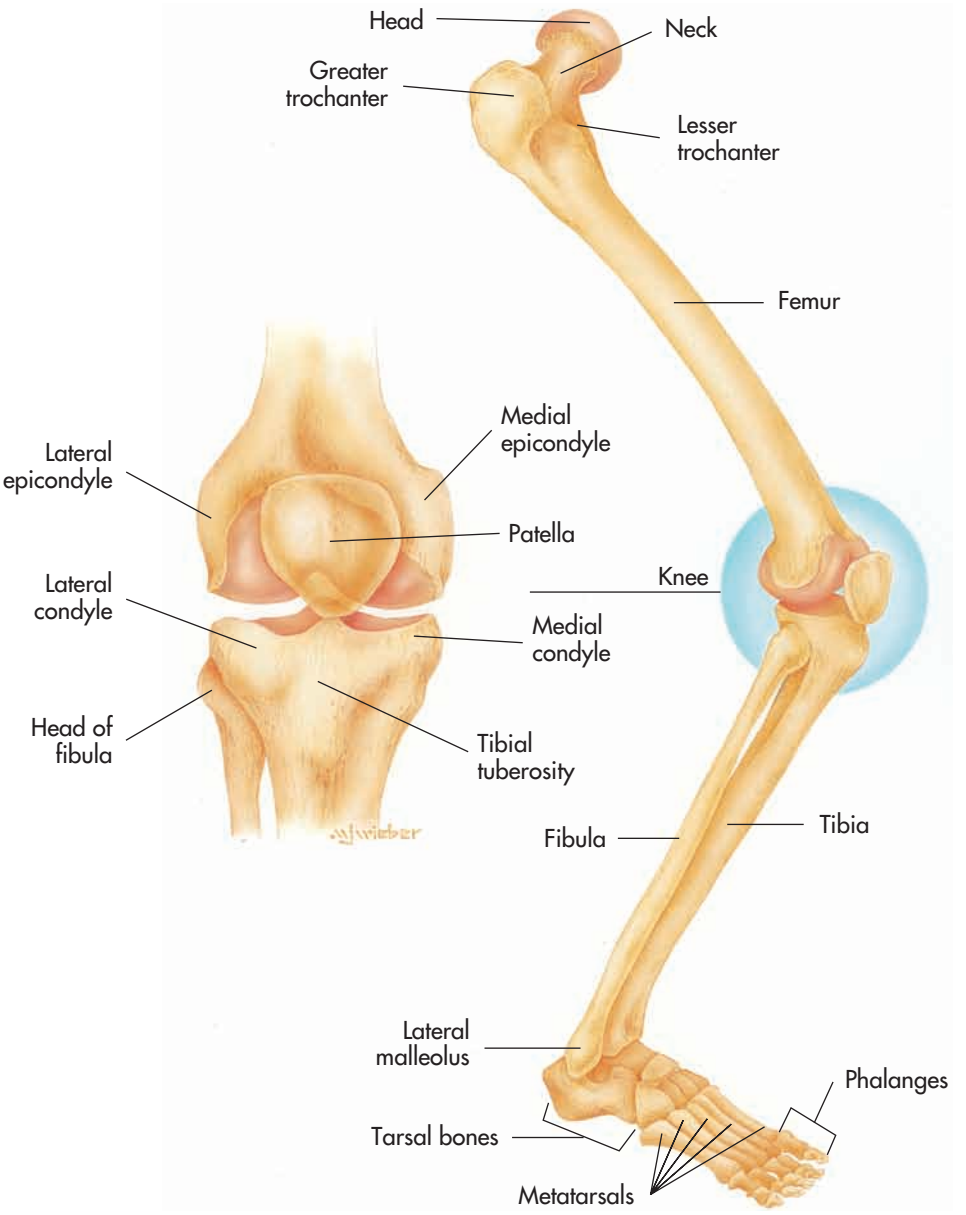

FIGURE 10-16 Bones of the lower extremity.

The connections, or joints, commonly are named according to the bones or portions of bones that are united at the joint. The three major classifications of joints are fibrous joints, cartilaginous joints, and synovial joints.

Fibrous Joints. Fibrous joints consist of two bones united by fibrous tissue; these joints have little or no movement. Fibrous joints are further classified, based on structure, as sutures, syndesmoses, or gomphoses. *Sutures* (seams between flat bones) are located in the skull bones and may be completely immobile in adults. In newborns, the sutures have gaps between them, called *fontanels* (Figure 10-18); these gaps are fairly wide to allow "give" to the skull during birth and to allow growth of the head during development.

A *syndesmosis* is a fibrous joint in which the bones are separated by a greater distance than in a suture and are joined by ligaments. These ligaments may provide some movement of the joint. An example of this type of joint is the *radioulnar syndesmosis,* which binds the radius and ulna together (Figure 10-19).

CRITICAL THINKING

Why might the structure of the skull sutures be a disadvantage with head trauma in an adult?

A *gomphosis* consists of a peg that fits into a socket. The peg is held in place by fine bundles of collagenous

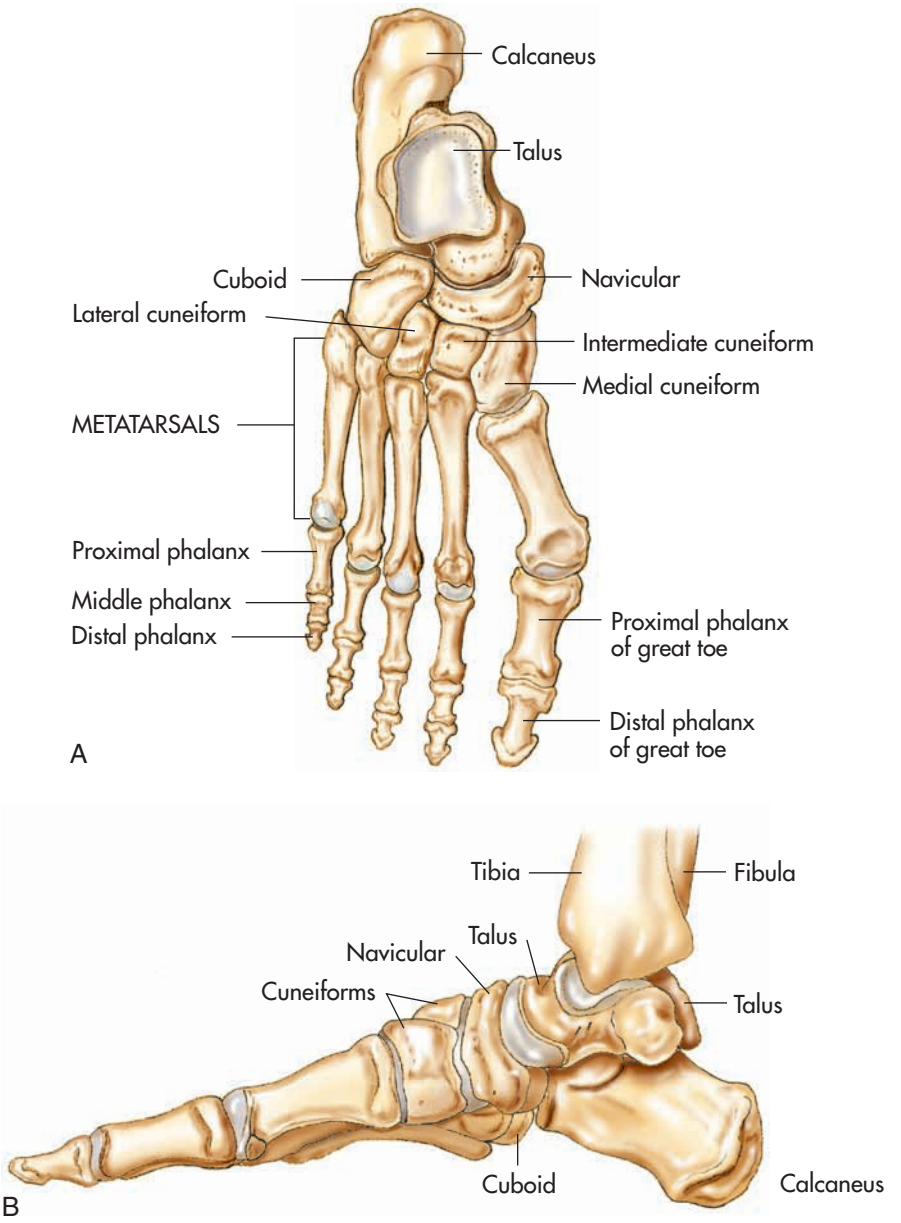

FIGURE 10-17 Bones of the right ankle and foot. **A,** Dorsal view. **B,** Medial view.

connective tissue. The joints between the teeth and the sockets along the processes of the mandible and maxilla are examples of gomphoses.

Cartilaginous Joints. Cartilaginous joints unite two bones by means of hyaline cartilage (synchondroses) or fibrocartilage (symphyses). A synchondrosis allows only slight movement at the joint. A common example of this type of joint is the epiphyseal plate of a growing bone. Another example is the cartilage rod between most of the ribs and the sternum. Symphyseal joints are slightly movable because of the flexible nature of the fibrocartilage. Symphyses include the junction between the manubrium and the body of the sternum in adults, the symphysis pubis of the coxae, and the intervertebral disks.

Synovial Joints. Synovial joints contain synovial fluid, which is a thin lubricating film that allows considerable movement between articulating bones. Most joints that unite the bones of the appendicular skeleton are synovial. The articular surfaces of bones in synovial joints are covered with a thin layer of hyaline cartilage. This cartilage provides a smooth surface where the bones meet. The joint is enclosed by a **joint capsule**. The capsule consists of an outer fibrous capsule and an inner synovial membrane. The synovial membrane lines the joint and produces synovial fluid. Synovial joints are classified into six divisions according to the shape of the adjoining articular surfaces (Figure 10-20):

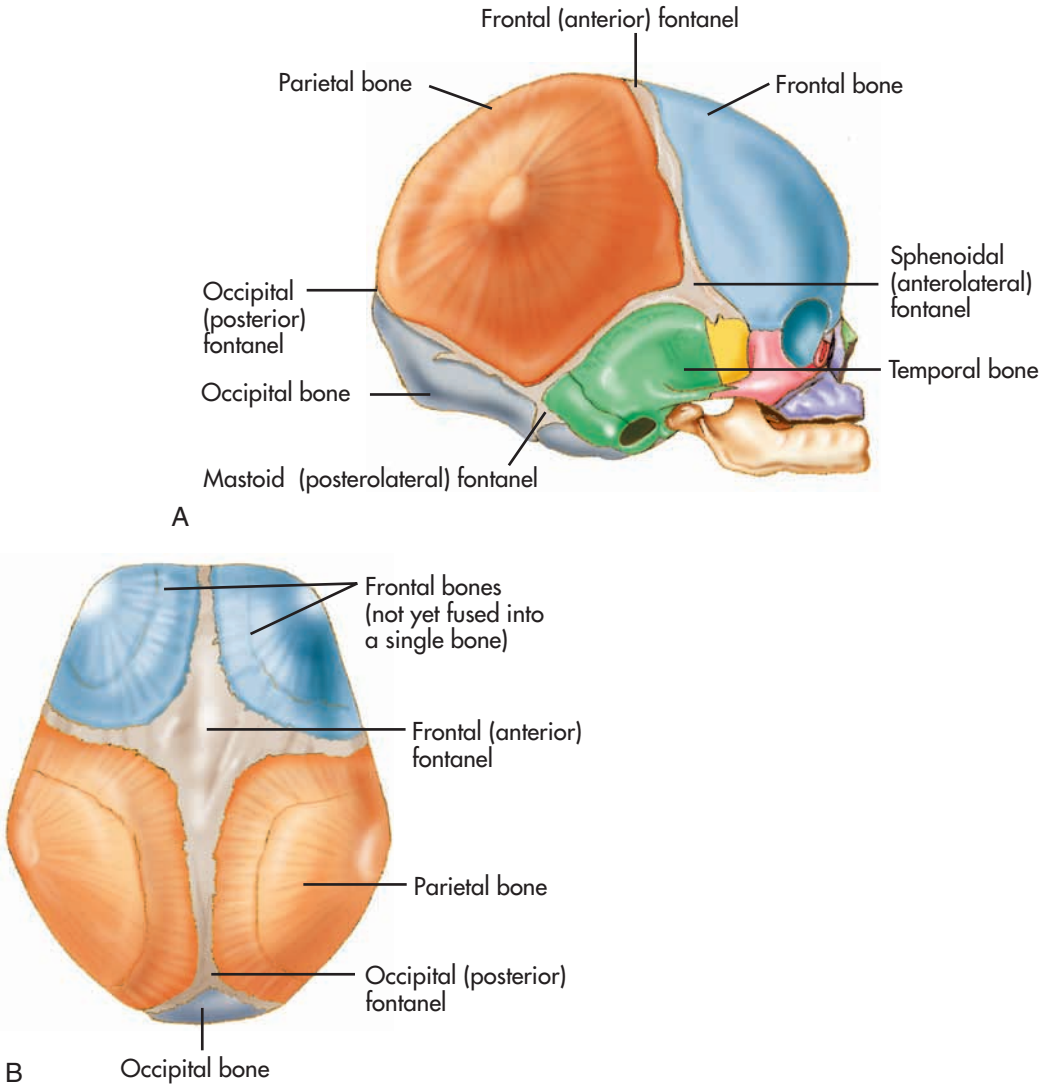

FIGURE 10-18 Fetal skull showing the fontanels. **A,** Lateral view. **B,** Superior view.

1. *Plane* or *gliding joints* consist of two opposed flat surfaces that are about equal in size. Examples of these joints are the articular processes between the vertebrae.
2. *Saddle joints* consist of two saddle-shaped articulating surfaces oriented at right angles to each other. Movement in these joints can occur in two planes. An example of a saddle joint is the carpometacarpal joint of the thumb.
3. *Hinge joints* consist of a convex cylinder in one bone applied to a corresponding concavity in another bone. These joints permit movement in one plane only. Examples of hinge joints are the joints of the elbow and knee.
4. *Pivot joints* consist of a relatively cylindrical bony process. This process rotates within a ring composed partly of bone and partly of ligament. An example of a pivot joint is the articulation of the head of the radius with the proximal end of the ulna.
5. *Ball-and-socket joints* consist of a ball (head) at the end of one bone and a socket in an adjacent bone into which a portion of the ball fits. These joints allow wide ranges of movement in almost any direction. Examples are the shoulder and hip joints.
6. *Ellipsoid joints* are modified ball-and-socket joints. The articular surfaces are ellipsoid rather than spherical. The shape of the joint limits movement, making it similar to a hinge motion, but the motion occurs in two planes. The *atlantooccipital joint* is an ellipsoid joint.

Types of Movement. Movement may be described as it relates to the position of the body.[3] In other words, movement can be described by motion away from the anatomical position or motion toward it. (Table 10-3 lists examples of each type of movement; also see Figures 10-21 to 10-25.)

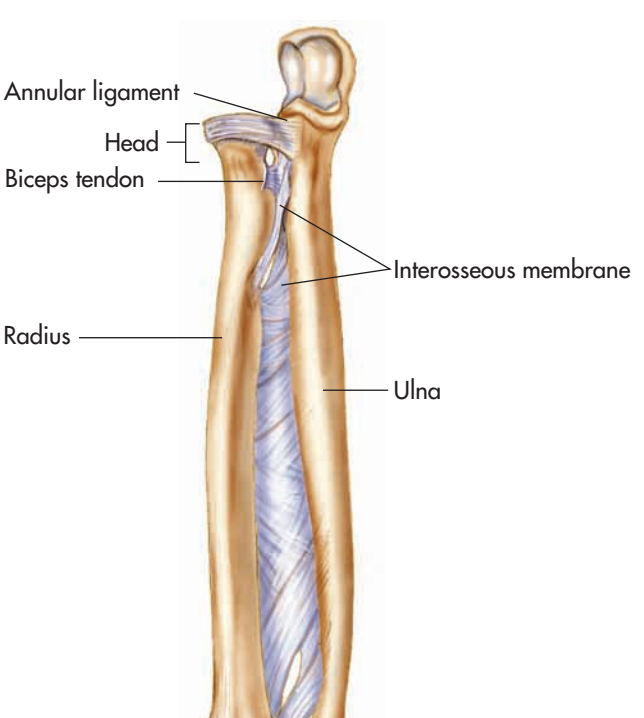

FIGURE 10-19 Radioulnar syndesmosis of the right forearm.

TABLE 10-3 Body Movement Terminology

Term	Definition
Flexion	Bending
Extension	Stretching out
Protraction	Movement in the anterior direction
Retraction	Movement in the posterior direction
Abduction	Movement away from the midline
Adduction	Movement toward the midline
Inversion	Turning inward
Eversion	Turning outward
Excursion	Movement from side to side
Rotation	Movement of a structure around its axis
Circumduction	Movement in a circular motion
Pronation	Rotation of the forearm so that the anterior surface is down
Supination	Rotation of the forearm so that the anterior surface is up
Elevation	Movement of a structure in a superior direction
Depression	Movement of a structure in an inferior direction
Opposition	Movement of the thumb and little finger toward each other
Reposition	Movement of a structure to its original position

CRITICAL THINKING
Why would it be an asset to use movement terms in your radio report or written patient care report?

Muscular System

The three primary functions of the muscular system are movement, postural maintenance, and heat production. As previously discussed, the major types of muscles are skeletal, cardiac, and smooth muscle. Skeletal muscle is far more common than other types of muscle in the body and is the focus of this section. Cardiac and smooth muscle are presented later in this text. (Table 10-4 compares these muscle types.)

PHYSIOLOGY OF SKELETAL MUSCLE

Muscle tissue is made up of specialized contractile cells or muscle fibers. Skeletal muscle contracts in response to electrochemical stimuli. Nerve cells regulate the function of skeletal muscle fibers by controlling the series of events that results in muscle contraction.

Each skeletal muscle fiber is filled with thick and thin **myofilaments**. These are fine, threadlike structures. The *thick myofilaments* are formed from the protein *myosin*. The *thin myofilaments* are composed of the protein *actin*. The **sarcomere**, the contractile unit of skeletal muscle, contains thick and thin myofilaments. During the contraction process, energy obtained from ATP molecules enables the two types of myofilaments to slide toward each other, shortening the sarcomere and eventually the entire muscle.

A nervous impulse enters the muscle fiber through a specialized nerve known as a **motor neuron**. The point of contact between the nerve ending and the muscle fiber is the neuromuscular junction, or **synapse** (Figure 10-26). Each muscle fiber receives a branch of an axon. Each axon innervates more than a single muscle fiber. When a nerve impulse passes through this junction, specialized chemicals are released, causing the muscle to contract.

CRITICAL THINKING
Consider that exposure to a chemical nerve weapon caused too much chemical stimulation at the synapse for the muscles of the eye. What might you find in your examination of the eye?

SKELETAL MUSCLE MOVEMENT

Most muscles extend from one bone to another and cross at least one joint. Muscle contraction causes most body movements by pulling one of the bones toward the other across the movable joint. The points of attachment of each muscle are the origin and the insertion. The *origin* is the end of the muscle attached to the more stationary of the two bones. The *insertion* is the end of the muscle attached to the bone undergoing the greatest movement. Some muscles of

TABLE 10-4 Comparison of Muscle Types

Features	Skeletal Muscle	Cardiac Muscle	Smooth Muscle
Location	Attached to bones	Heart	Walls of hollow organs, blood vessels, eyes, glands, and skin
Cell shape	Long and cylindrical (1-40 mm in length; may extend the entire length of a muscle; 10-100 µm in diameter)	Cylindrical and branched (100-500 µm in length; 100-200 µm in diameter)	Spindle-shaped (15-200 µm in length, 5-10 µm in diameter)
Nucleus special features	Multiple, peripherally located	Single, centrally located Intercalated disks join the cells to each other	Single, centrally located
Striations	Yes	Yes	No
Control	Voluntary	Involuntary	Involuntary
Capable of spontaneous contraction	No	Yes	Yes
Function	Body movement	Pumps blood	Food movement through the digestive tract, emptying of the urinary bladder, regulation of blood vessel diameter, change in pupil size, contraction of many gland ducts, movement of hair, and many other functions

the face are not attached to bone at both ends; rather, they attach to the skin, which moves when muscles contract.

As some muscles contract and others relax at the same time, movement is created. Muscles that work together to cause movement are called *synergists*. A muscle that opposes another muscle (moves the structure in an opposite direction) is called an *antagonist*. The muscle that is the main cause of a movement is called the *prime mover*. For example, the biceps brachii, brachialis, and triceps brachii muscles are involved in flexion and extension of the forearm at the elbow joint. The *biceps brachii* is the prime mover during flexion. The *brachialis* is the synergistic muscle. When the biceps brachii and the brachialis muscles flex the forearm, the *triceps brachii* relaxes. The triceps is the antagonist. During extension of the forearm, the triceps brachii is the prime mover. The biceps and brachialis are the antagonistic muscles. The synergists and antagonists coordinate their activity, making movement smooth (Figure 10-27).

Types of Muscle Contraction. Muscle contractions can be labeled as *isometric* or *isotonic*. This depends on the type of contraction that predominates. In isometric contractions the length of the muscle does not change. However, the amount of tension increases during the contraction. Isometric contractions are responsible for the constant length of the postural muscles of the body. During isotonic contractions, the amount of tension created by the muscle is constant, but the length of the muscle changes. An example of isotonic contraction is the movement of the arms or fingers. Most muscle contractions are a mix of the two types of contractions.

Postural Maintenance. Postural maintenance is a result of muscle tone, the constant tension produced by muscles of the body for long periods. This tone keeps the back and legs straight, the head in an upright position, and the abdomen from bulging. These positions balance the distribution of weight. Therefore, they put less strain on muscles, tendons, ligaments, and bones.

Heat Production. The energy needed to create muscle contraction is derived from ATP. Most of the energy released in the breakdown of ATP during a muscular contraction is used to shorten the muscle fibers. Some energy, though, is lost as heat during the chemical reaction. The normal body temperature comes in large part from this metabolism in skeletal muscle. If the body temperature drops below a certain level, the nervous system induces shivering. Shivering is rapid contractions of skeletal muscle that produce shaking rather than coordinated movements. The muscle movement increases heat production up to 18 times that of resting levels. The heat made during shivering can exceed that from moderate exercise. This helps to raise the body temperature to its normal range.

CRITICAL THINKING

Children under 3 months of age cannot shiver. How will you account for that in your prehospital care for patients in this age group?

Nervous System

The nervous system and the endocrine system are the main regulatory and coordinating systems of the body. The nervous system rapidly sends out information. This occurs by means of nerve impulses conducted from one area of the body to another. The endocrine system sends out information more slowly. This takes place by means of chemicals secreted by ductless glands into the bloodstream. These chemicals and hormones then are circulated to other parts of the body. The constancy of the internal environment of the body is **homeostasis**. This constancy is sustained to a large degree by these regulatory and coordinating actions.

DIVISIONS OF THE NERVOUS SYSTEM

The human body has a single nervous system. This is the case even though some of its subdivisions are referred to as separate systems. Each subdivision has structural and functional aspects that distinguish it from the others (Figure 10-28).

The **central nervous system (CNS)** is made up of the brain and spinal cord. These organs are encased in and protected by bone. The brain and spinal cord are continuous with each other. The **peripheral nervous system (PNS)** consists of the nerves and ganglia. The **ganglia** are collections of nerve cell bodies located outside the CNS. Forty-three pairs of nerves originate from the CNS to form the PNS; 12 pairs, the cranial nerves, originate from the brain, and the remaining 31 pairs, the spinal nerves, originate from the spinal cord. The **afferent division** transmits action potentials from the sensory organs to the CNS. The **efferent division** transmits action potentials from the CNS to effector organs such as muscles and glands (Figure 10-29). The efferent division is divided further into the **somatic nervous system** and the **autonomic nervous system**. The somatic nervous system transmits impulses from the CNS to skeletal muscle. The autonomic nervous system transmits action potentials from the CNS to smooth muscle, cardiac muscle, and certain glands.

CRITICAL THINKING

How are the cranial nerves like the Supreme Court?

CENTRAL NERVOUS SYSTEM

As stated before, the CNS consists of the brain and spinal cord. The adult brain has four major regions: the brainstem (consisting of the medulla, pons, and midbrain); the diencephalon (which includes the thalamus and hypothalamus); the cerebrum; and the cerebellum (Figure 10-30). Table 10-5 describes the functions of these divisions.

Brainstem. The medulla, pons, and midbrain constitute the brainstem. The brainstem connects the spinal cord to the remainder of the brain and is responsible for many essential functions. All but two of the 12 cranial nerves enter or exit the brain through the brainstem.

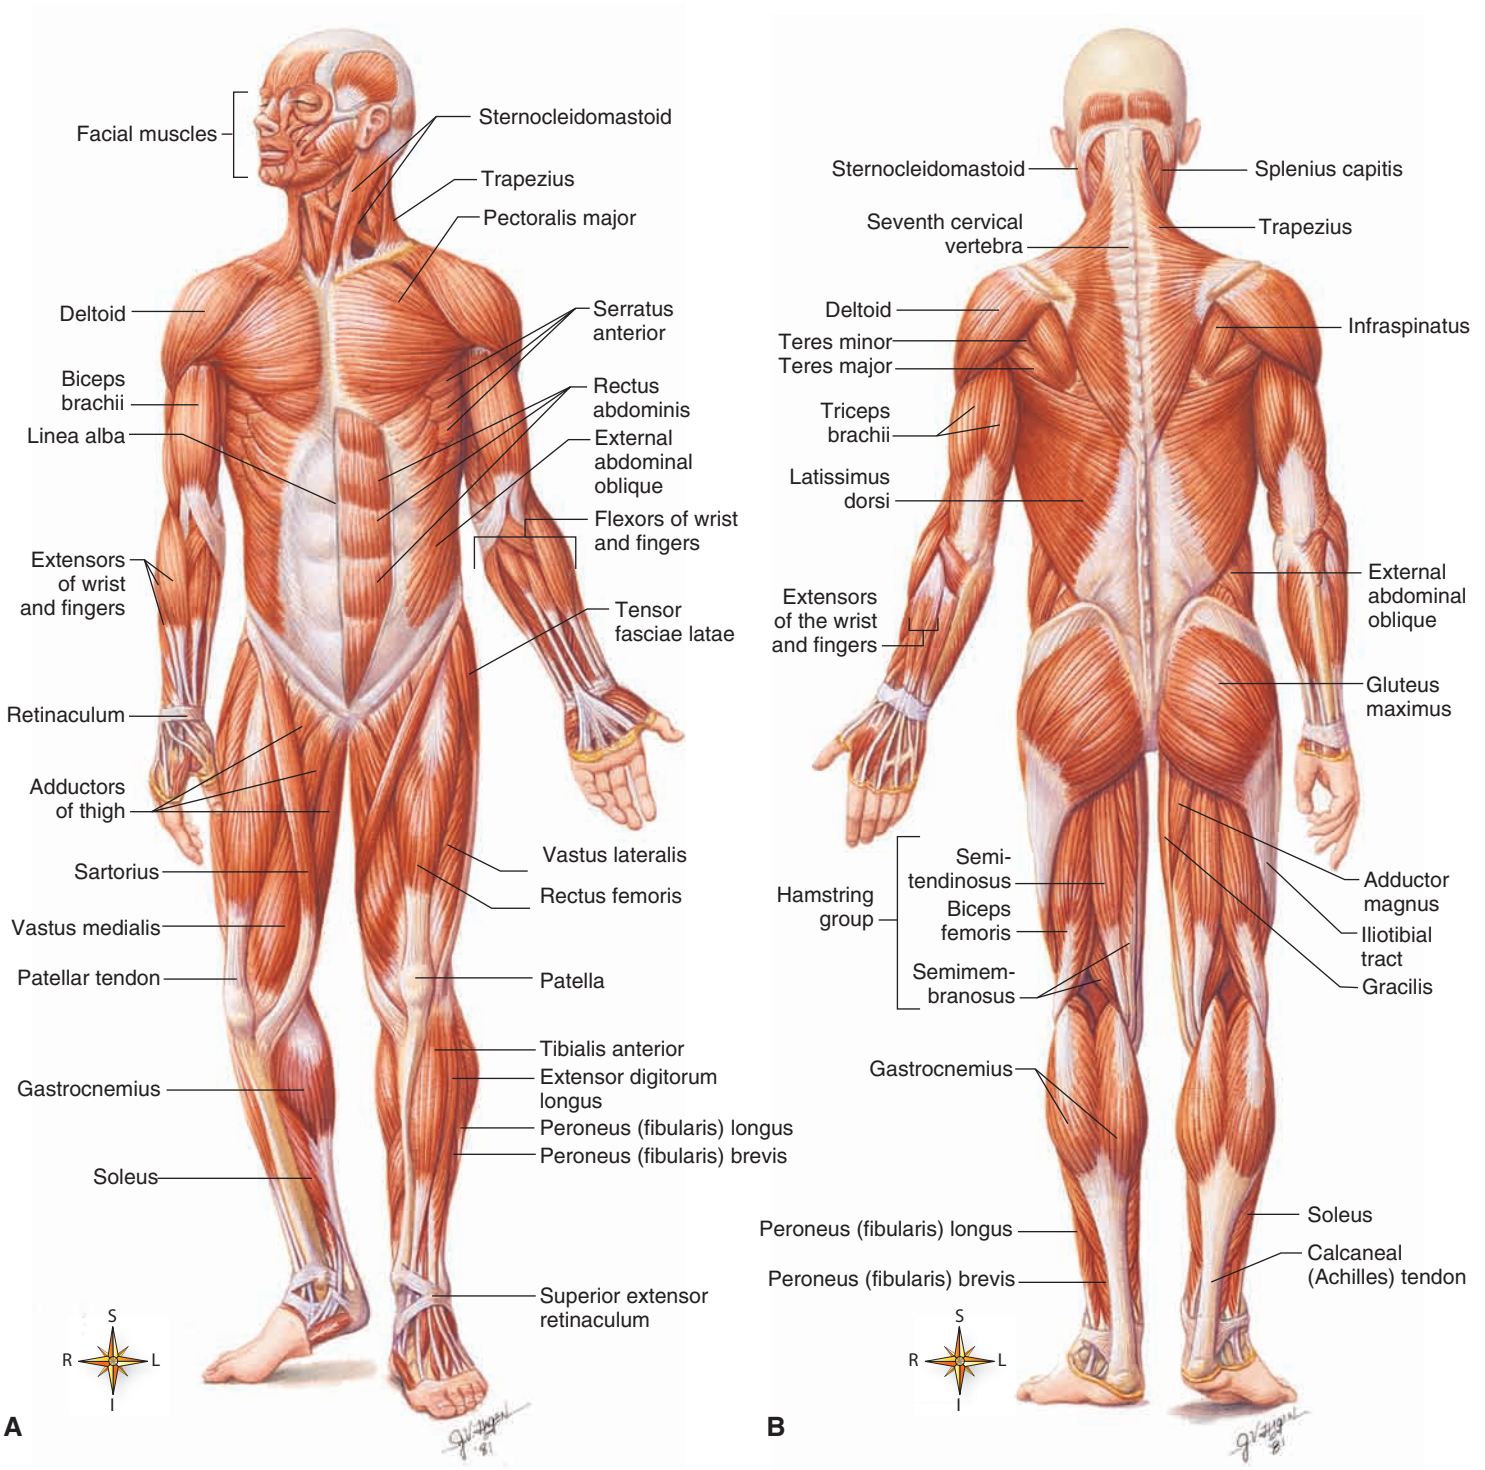

FIGURE 10-27 **A,** Anterior view of the body's musculature. **B,** Posterior view of the body's musculature. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

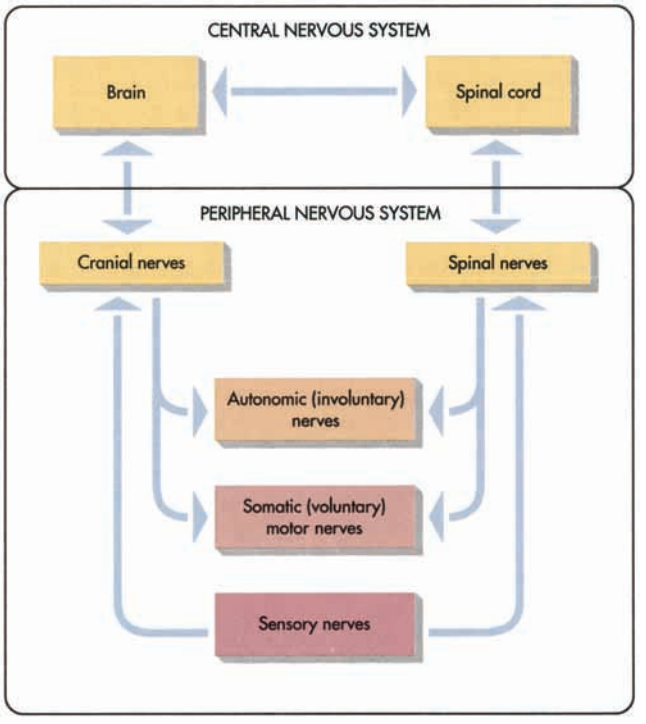

FIGURE 10-28 Divisions of the nervous system. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

The **medulla**, also known as the *medulla oblongata,* is the most inferior portion of the brainstem. The medulla acts as a conduction pathway for ascending and descending nerve tracts. It controls several body functions, such as regulation of the heart rate, blood vessel diameter, breathing, swallowing, vomiting, coughing, and sneezing.

CRITICAL THINKING

You have a patient with an injury that affects the medulla. What is the initial prehospital management priority? Why?

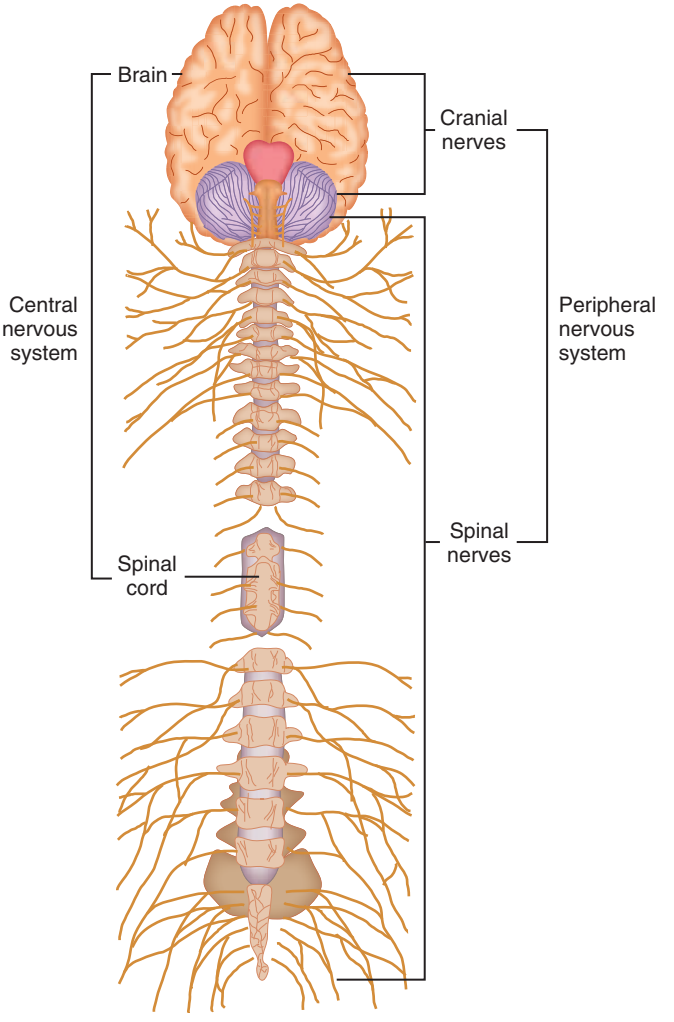

FIGURE 10-29 The central nervous system consists of the brain and spinal cord. The peripheral nervous system consists of the cranial nerves, which arise from the brain, and the spinal nerves, which arise from the spinal cord.

The **pons** contains ascending and descending nerve tracts. It relays information from the cerebrum to the cerebellum. In addition, the pons houses the sleep center and respiratory center that, along with the medulla, help control breathing.

The midbrain, or **mesencephalon**, is the smallest region of the brainstem. The midbrain is involved in hearing through audio pathways in the CNS. The midbrain also is involved in visual reflexes such as visual tracking of moving objects and turning of the eyes. Other parts of the midbrain help regulate the automatic functions that require no conscious thought. These functions include, for example, coordination of motor activities and muscle tone.

The **reticular formation** is a group of nuclei scattered throughout the brainstem. It receives axons from a large number of sources, especially from the nerves that innervate the face. The reticular formation and its connections are known as the **reticular activating system**. This system is involved in the sleep-wake cycle. The reticular activating system also is important in arousing and maintaining consciousness. Coma after head injury results from damage to this system.

Diencephalon. The **diencephalon** is the part of the brain between the brainstem and the cerebrum. Major components of this organ include the thalamus and hypothalamus. The **thalamus** is the largest portion of the diencephalon. It receives sensory input from various sense organs of the body and relays these impulses to the **cerebral cortex**. The thalamus also has other functions, such as influencing mood and general body movements linked with strong emotions such as fear or rage.

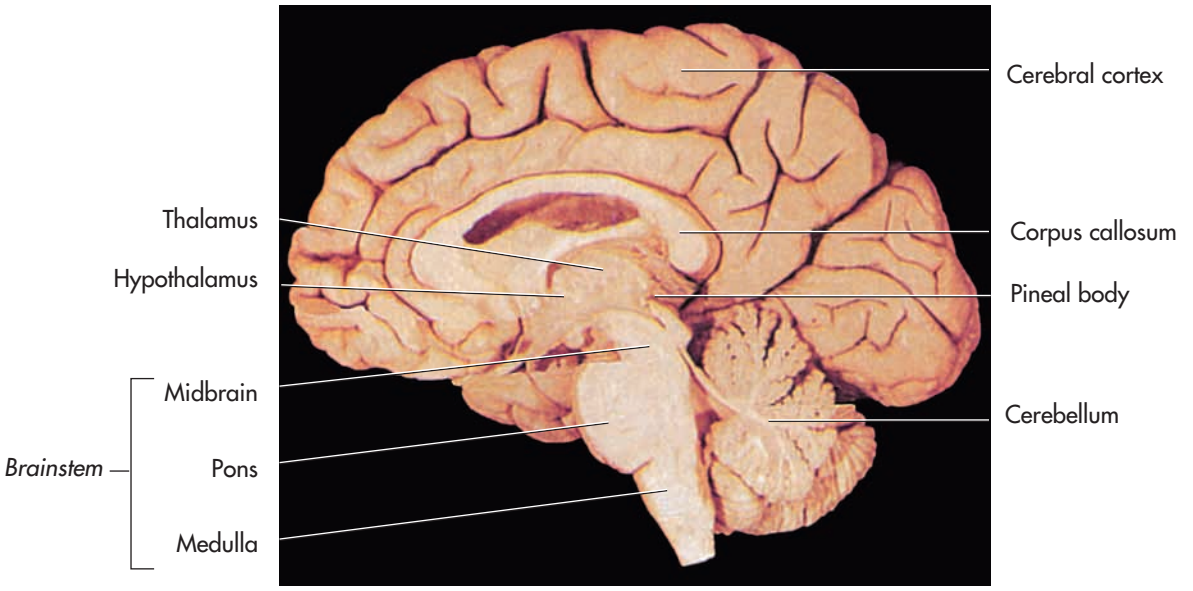

FIGURE 10-30 Section of preserved brain. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

TABLE 10-5 Functions of Major Divisions of the Brain

Brain Area	Function
Brainstem	
Medulla	Two-way conduction pathway between the spinal cord and higher brain centers; cardiac, respiratory, and vasomotor control centers
Pons	Two-way conduction pathway between areas of the brain and other regions of the body; influences respiration
Midbrain	Two-way conduction pathway; relay point for visual and auditory impulses
Diencephalon	
Hypothalamus	Regulation of body temperature, water balance, sleep-cycle control, appetite, and sexual arousal
Thalamus	Sensory relay station from various body areas to cerebral cortex; emotions and alerting or arousal mechanisms
Cerebellum	Muscle coordination; maintenance of equilibrium and posture
Cerebrum	Sensory perception, emotions, willed movements, consciousness, and memory

The **hypothalamus** is a major controller in the brain. It acts as a gatekeeper in determining what information is passed along to the cerebrum. The hypothalamus is an active participant in emotions, hormonal cycles, and sexuality. (Table 10-6 gives a summary of the various hypothalamic functions.)

Cerebrum. The **cerebrum** is the largest portion of the brain. It is divided into left and right hemispheres, and each hemisphere is divided into lobes named for the bones that lie over them (Figure 10-31).

The *frontal lobe* is important in voluntary motor function, motivation, aggression, and mood. The *parietal lobe* is the major center for the reception and evaluation of most sensory information, except for smell, hearing, and vision. The *occipital lobe* functions in the reception and integration of visual input. The occipital lobe is not distinctly separate from other lobes. The *temporal lobe* receives and evaluates olfactory and auditory input. The temporal lobe plays a key role in memory. A thin layer of **gray matter**, made up of neuron dendrites and cell bodies, composes the surface of the cerebrum (cerebral cortex).

The **limbic system** is made up of portions of the cerebrum and diencephalon. This system influences emotions, visceral responses to those emotions, motivation, mood, and sensations of pain and pleasure.

Cerebellum. The **cerebellum** is the second largest part of the human brain. It is involved in gross motor coordination and helps produce smooth movements. A major job of the cerebellum is to compare impulses from the motor cortex with those from moving structures (e.g., the position of the body or of body parts that innervate the joints and tendons of the structure being moved). The cerebellum compares the intended movement with the actual one. If a difference is detected, the cerebellum sends impulses to the motor cortex and the spinal cord to correct the discrepancy. Loss of cerebellar functioning results in inability to make exact movements.

Spinal Cord. The spinal cord lies within the spinal column and extends from the occipital bone to the level of the second lumbar vertebra. The spinal cord has a *central*

TABLE 10-6 Hypothalamic Functions

Function	Description
Autonomic	Helps control heart rate, urine release from the bladder, movement of food through the digestive tract, and blood vessel diameter.
Endocrine	Helps regulate pituitary gland secretions and influences metabolism, ion balance, sexual development, and sexual functions.
Muscle control	Controls muscles involved in swallowing and stimulates shivering in several muscles.
Temperature regulation	Promotes heat loss when the hypothalamic temperature increases by increasing sweat production (anterior hypothalamus) and promotes heat production when the hypothalamic temperature decreases by promoting shivering (posterior hypothalamus).
Regulation of food and water intake	Hunger center promotes eating, and satiety center inhibits eating; thirst center promotes water intake.
Emotions	Large range of emotional influences over body functions; directly involved in stress-related and psychosomatic illnesses and with feelings of fear and rage.
Regulation of the sleep-wake cycle	Coordinates responses to the sleep-wake cycle with other areas of the brain (e.g., the reticular activating system).

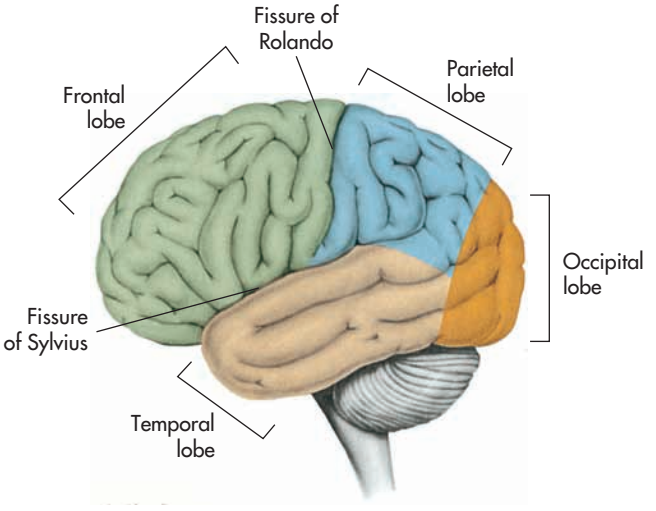

FIGURE 10-31 Lobes of the cerebrum. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

gray portion and a *peripheral white portion*. The white matter consists of nerve tracts, and the gray matter consists of nerve cell bodies and dendrites. The **dorsal root** conveys afferent nerve processes to the cord, and the **ventral root** conveys efferent nerve processes away from the cord. Spinal ganglia, or dorsal root ganglia, contain the cell bodies of sensory neurons (Figure 10-32).

CRITICAL THINKING

An older adult patient has a new onset of staggering gait. What area of the brain do you suspect has altered function?

The spinal cord is the main reflex center of the body. Many of these reflexes are **autonomic** or **visceral**. An example of this is an increased heart rate in response to decreased blood pressure. Another example is the stretch reflex (knee-jerk reflex). The body also has withdrawal reflexes (i.e., removing a limb or other body part from a painful stimulus). In addition to acting as a primary reflex center, the spinal cord tracts carry impulses to the brain in afferent, ascending tracts. These tracts also carry motor impulses from the brain in efferent, descending tracts. (Ascending and descending pathways are addressed further in Chapter 25.)

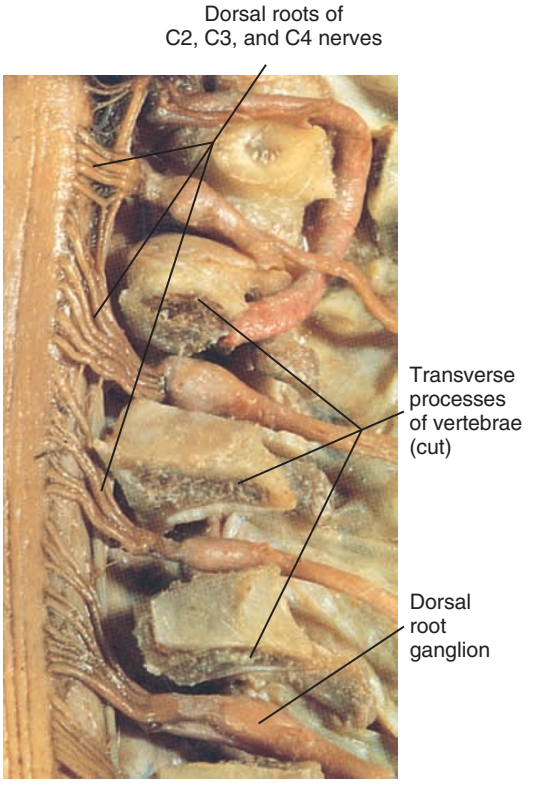

FIGURE 10-32 Dissection of the cervical segment of the spinal cord. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

The organs of the nervous system are surrounded by a tough, fluid-containing membrane. This membrane is known as the **meninges**. The meninges are surrounded by bone and have three connective tissue layers. The most superficial and thickest layer is the **dura mater**. It consists of two layers around the brain and one layer around the spinal cord. The two layers of the dura mater are fused around most of the brain but are separate in several places. The dura mater of the brain is attached tightly and is continuous with the **periosteum** of the cranial vault, whereas the dura mater of the spinal cord is separated from the periosteum of the vertebral canal by the **epidural space**.

The **arachnoid layer** is the second meningeal layer. The space between this layer and the dura mater is known as the **subdural space**, which contains a small amount of serous fluid. The third meningeal layer is the pia mater. The **pia mater** lies external to a basement membrane formed by special cells called the *glia limitans*, which completely envelops the CNS. The space between the pia mater and the arachnoid layer is the **subarachnoid space**. This space is filled with blood vessels and cerebrospinal fluid (Figure 10-33).

The **cerebrospinal fluid (CSF)** is similar to plasma and **interstitial fluid** (the fluid that occupies the space outside the blood vessels). CSF bathes the brain and spinal cord and acts as a cushion around the CNS. It is formed continually from fluid filtering out of the blood in a network of brain capillaries and cells known as the *choroid plexus*. This special fluid fills the ventricles of the brain, the subarachnoid space, and the central canal of the spinal cord.

PERIPHERAL NERVOUS SYSTEM

The PNS collects information from numerous sources inside the body and on the body surface. The PNS relays this information by way of afferent fibers to the CNS. The CNS then evaluates the information. Efferent fibers in the PNS relay information from the CNS to various parts of the body, primarily to muscles and glands.

Spinal Nerves. The **spinal nerves** arise from many rootlets along the dorsal and ventral surfaces of the spinal cord. All of the 31 pairs of spinal nerves, except for the first pair of spinal nerves and the spinal nerves in the sacrum, exit the vertebral column though adjacent vertebrae. The first pair of spinal nerves exits between the skull and the first cervical vertebrae. The spinal nerves in the sacrum exit through the bone. Eight spinal nerve pairs exit the vertebral column in the cervical region, 12 in the thoracic region, 5 in the lumbar region, 5 in the sacral region, and 1 in the coccygeal region (Figure 10-34).

Each spinal nerve except the first has a specific cutaneous sensory distribution. Detailed mapping of the skin surface reveals a close relationship between the source on the cord of each spinal nerve and the level of the body it innervates. (A grasp of this relationship is vital when the paramedic examines a patient with a spinal cord injury.) The skin surface areas supplied by a single spinal nerve are known as **dermatomes** (Figure 10-35).

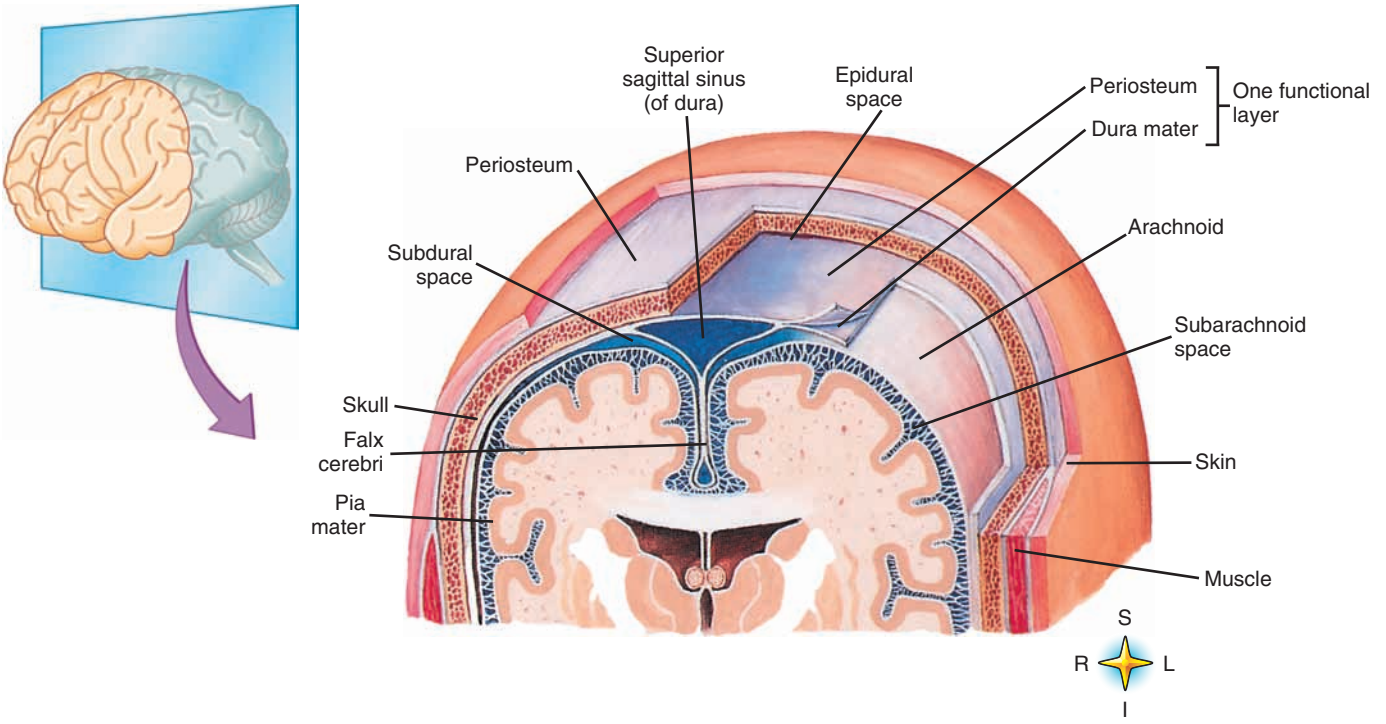

FIGURE 10-33 Meningeal coverings of the brain and spinal cord. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

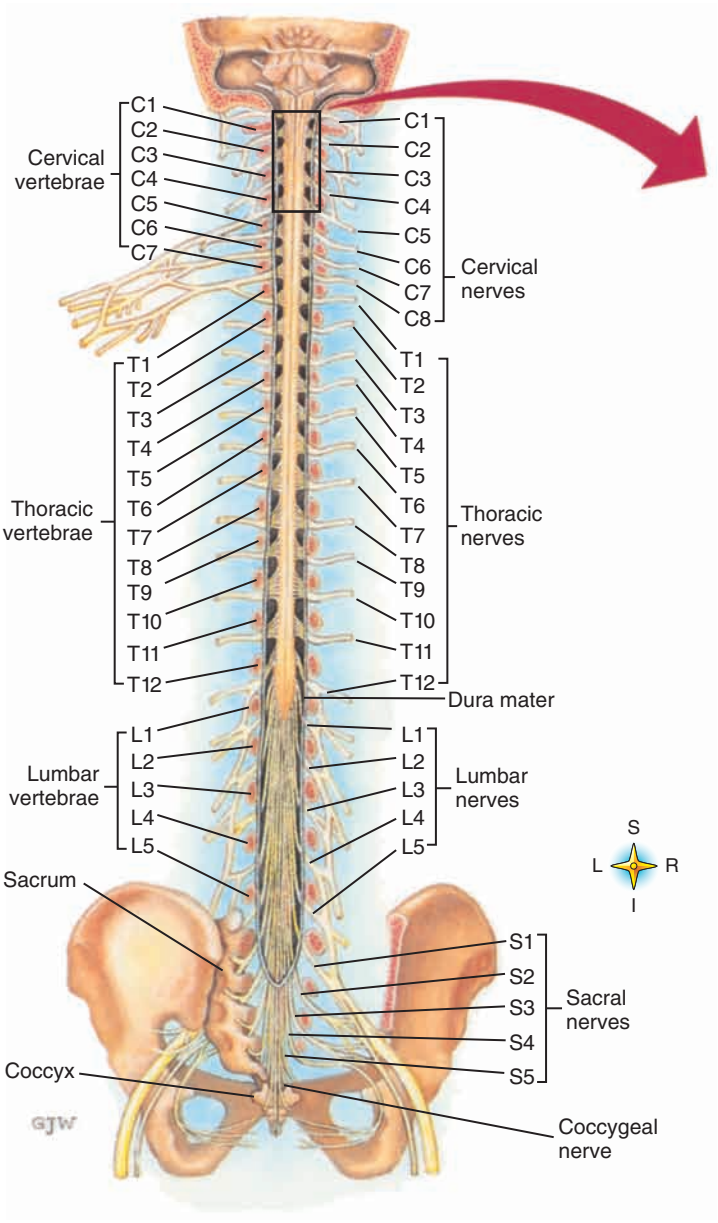

FIGURE 10-34 Spinal cord and spinal nerves. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

CRITICAL THINKING
Does a person with a spinal cord injury at the C5 level have movement in the hands?

Cranial Nerves. The 12 cranial nerves are divided into three general groups: sensory, somatomotor and proprioception, and parasympathetic (Figure 10-36). *Sensory functions* include the special senses, such as vision. They also include the more general senses, such as touch and pain. *Somatomotor functions* control the skeletal muscles through motor neurons. *Proprioception* provides the brain with information about the position of the body and its various parts, including joints and muscles. *Parasympathetic function* involves the regulation of glands, smooth muscle, and cardiac muscle (functions of the autonomic nervous system). Some cranial nerves have only one of the three functions. However, other cranial nerves have more than one function (Table 10-7).

AUTONOMIC NERVOUS SYSTEM

As stated before, the PNS is made up of afferent and efferent neurons. **Afferent neurons** carry action potentials from the periphery to the CNS. **Efferent neurons** carry action potentials from the CNS to the periphery. Afferent neurons give information to the CNS. These data may stimulate somatomotor and autonomic reflexes. Therefore, afferent neurons cannot be put easily into groups by function. However, efferent neurons clearly differ structurally and functionally. They can be put into the somatomotor nervous system or the autonomic nervous system.

Somatomotor neurons innervate skeletal muscles. These neurons play a key role in locomotion, posture, and equilibrium. The movements controlled by the somatomotor nervous system usually are conscious movements. The effect of these neurons on skeletal muscle is always excitatory. Neurons of the autonomic nervous system innervate smooth muscle, cardiac muscle, and glands. These neurons usually are controlled unconsciously. The effect of autonomic neurons on their target tissue is inhibitory or excitatory.

The autonomic nervous system is made up of two divisions, the **sympathetic nervous system** and the **parasympathetic nervous system**. Both of these divisions consist of autonomic ganglia and nerves. The action potentials in sympathetic neurons generally prepare a person for physical activity. Parasympathetic stimulation, however, activates vegetative functions such as digestion, defecation, and urination.

The functions of the autonomic nervous system help to maintain homeostasis or to quickly restore homeostasis (Table 10-8). Many internal organs receive fibers from parasympathetic and sympathetic divisions (Figure 10-37). Therefore, they are continually bombarded by sympathetic and parasympathetic impulses. These impulses influence the function of these organs in opposite or antagonistic ways. For example, the heart receives sympathetic impulses that increase the heart rate. The heart also receives parasympathetic impulses that decrease the heart rate. The ratio between these two forces determines the actual heart rate.

CRITICAL THINKING
You administer a drug that blocks the action of the parasympathetic nervous system. What happens to the patient's heart rate?

Endocrine System

The **endocrine system** is made up of glands. These glands secrete hormones into the circulatory system (Figure 10-38). The endocrine and nervous systems have considerable

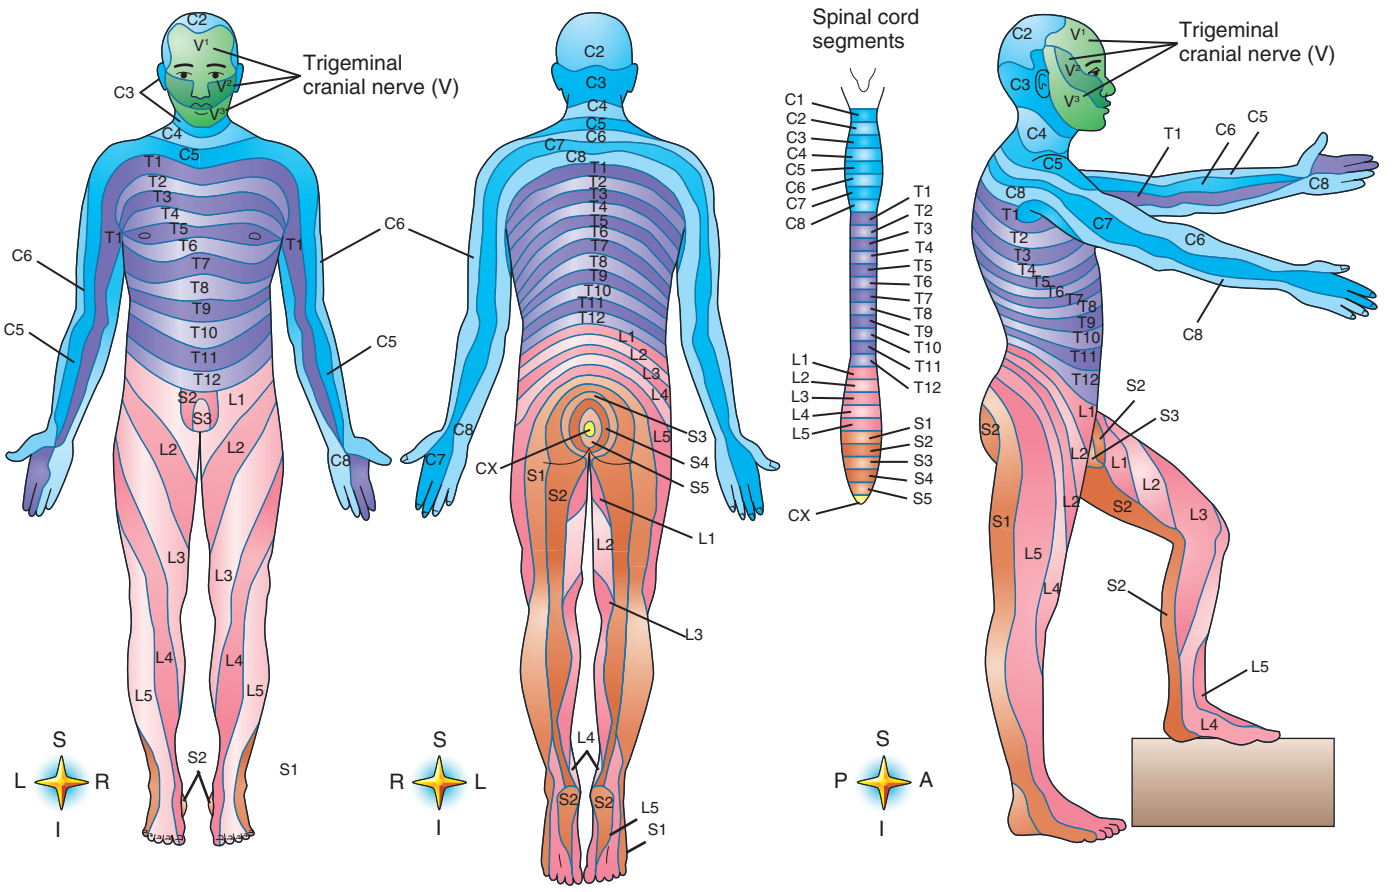

FIGURE 10-35 Dermatome map. Letters and numbers indicate the spinal nerves innervating a given region of the skin. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

overlap. The overlap is functional and anatomical. Some neurons secrete regulatory chemicals that function as hormones *(neurohormones)*, such as **antidiuretic hormone (ADH)**, into the circulatory system. Other neurons innervate **endocrine glands** and influence their secretory activity. However, some hormones secreted by the endocrine glands affect the nervous system.

Hormones, including neurohormones, are classified as proteins, polypeptides, derivatives of amino acids, or lipids. Lipid hormones are steroids or derivatives of fatty acids. Hormones are dissolved in blood plasma and are distributed quickly throughout the body. In general, the amount of hormone that reaches the target tissue directly correlates with the concentration of the hormone in the blood. (Table 10-9 lists endocrine glands, hormones, and their functions.)

Some hormones are present in fairly constant levels in the circulatory system. Amounts of other hormones change suddenly in response to certain stimuli. Still others change in fairly constant cycles. For example, *thyroid hormones* in the blood vary within a small range of concentrations. Their concentration is maintained continuously. *Epinephrine* is released in large amounts in response to stress or exercise. The concentration of epinephrine changes greatly. *Reproductive hormones* increase and decrease cyclically in women during their reproductive years.

Circulatory System

Blood vessels extend throughout the body. These vessels carry blood to and from all tissues. Blood performs a number of important functions: (1) it transports nutrients and oxygen to tissues; (2) it carries carbon dioxide and waste products away from tissues; (3) it carries hormones produced in the endocrine glands to their target tissues; (4) it plays a key role in temperature regulation and fluid balance; and (5) it protects the body from bacteria and foreign substances. These and other functions of blood help to maintain homeostasis.

BLOOD COMPONENTS

Blood is a special form of connective tissue. It consists of cells and cell fragments *(formed elements)* surrounded by a liquid intercellular matrix (plasma). About 95% of the volume of formed elements consists of red blood cells

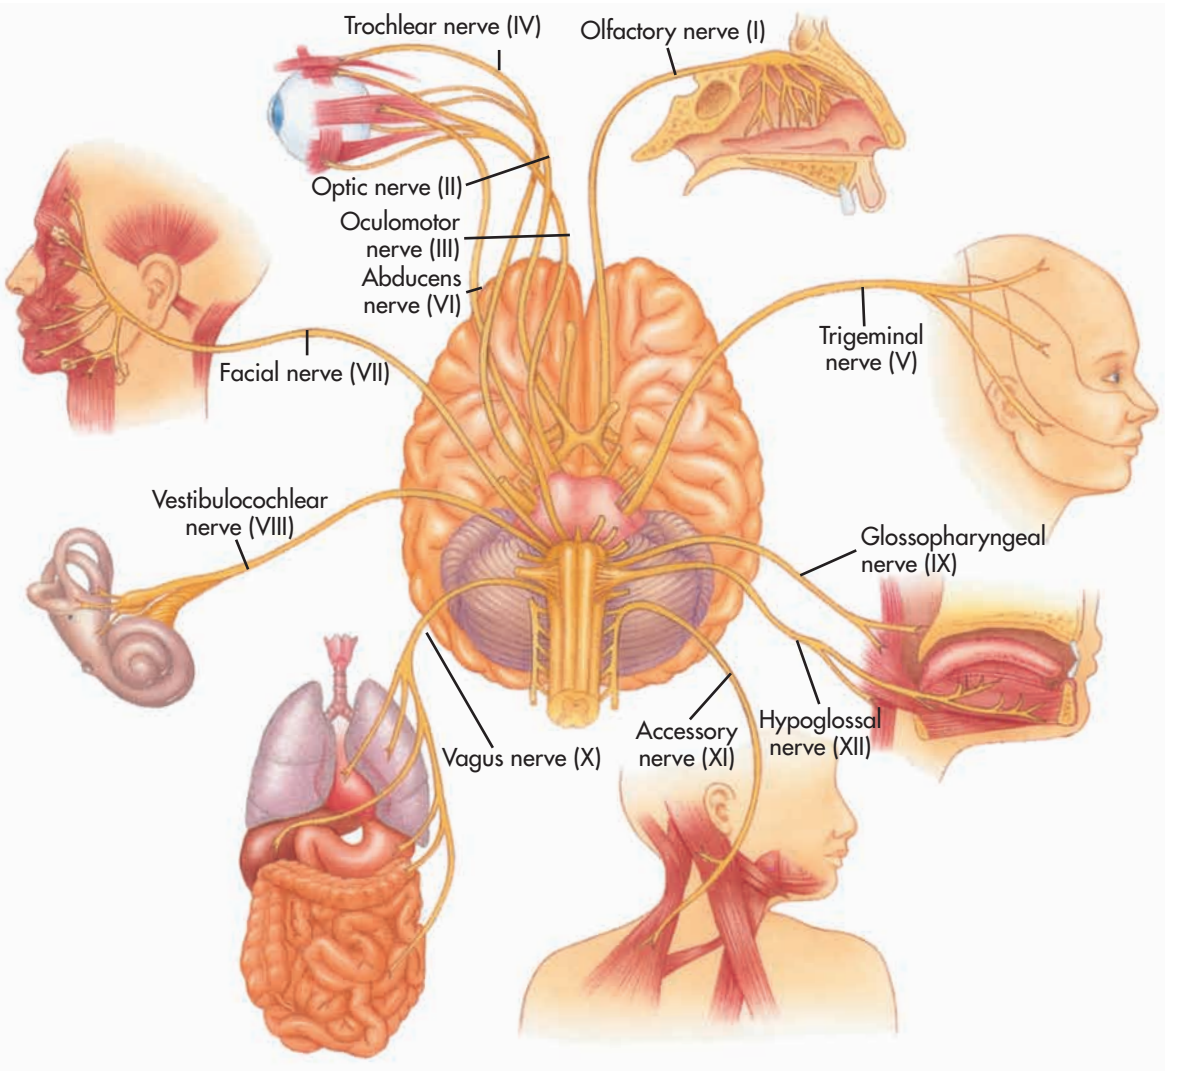

FIGURE 10-36 Origin of the cranial nerves. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

(erythrocytes). The remaining 5% consists of white blood cells (leukocytes) and cell fragments called *platelets.*

Plasma. Plasma is a pale yellow fluid composed of about 92% water and 8% dissolved or suspended molecules. Plasma contains proteins such as *albumin, globulins,* and *fibrinogen*. When the proteins that produce clots are removed from the plasma, the remaining fluid is called **serum**.

Formed Elements. Three formed elements of blood are erythrocytes, leukocytes, and platelets or thrombocytes (cell fragments) (Table 10-10). Formed elements are produced in the embryo and fetus. They are also produced in tissues such as the liver, thymus, spleen, lymph nodes, and red bone marrow.

1. **Erythrocytes** are the most numerous of the formed elements. One drop of male blood has about 5.2 million erythrocytes; one drop of female blood has about 4.5 million erythrocytes. The major erythrocyte contents include lipids, ATP, and the enzyme *carbonic anhydrase*. The main component of erythrocytes is **hemoglobin**. This is the protein that gives blood its red color. The primary functions of erythrocytes are to transport oxygen from the lungs to the various tissues of the body and to transport carbon dioxide from the tissues to the lungs. Under normal conditions, about 2.5 million erythrocytes are destroyed and replaced by the body each second. The average erythrocyte circulates for 120 days.

CRITICAL THINKING

If the number of erythrocytes drops, a person may become short of breath during mild exertion. Why does this happen?

TABLE 10-7 Functions of the Cranial Nerves

Nerve	Name	Impulse Conduction	Functions
I	Olfactory	From nose to brain	Sense of smell
II	Optic	From eye to brain	Vision
III	Oculomotor	From brain to eye muscles	Eye movements
IV	Trochlear	From brain to external eye muscles	Eye movements
V	Trigeminal	From skin and mucous membranes of head and from teeth to brain; also from brain to chewing muscles	Sensations of face, scalp, and teeth; chewing movements
VI	Abducens	From brain to external eye muscles	Turning eyes outward
VII	Facial	From taste buds of tongue to brain; from brain to facial muscles	Sense of taste; contraction of muscles of facial expressions
VIII	Acoustic	From ear to brain	Hearing; sense of balance
IX	Glossopharyngeal	From throat and taste buds of tongue to brain; also from brain to throat muscles and salivary glands	Sensation of throat, taste, swallowing movements; secretion of saliva
X	Vagus	From throat, larynx, and organs in thoracic and abdominal cavities to brain; also from brain to muscles of throat and to organs in thoracic and abdominal cavities	Sensations of throat and larynx and of thoracic and abdominal organs; swallowing, voice production, slowing of heartbeat, acceleration of peristalsis
XI	Spinal accessory	From brain to certain shoulder and neck muscles	Shoulder movements, turning movements of head
XII	Hypoglossal	From brain to muscles of tongue	Tongue movements

TABLE 10-8 Functions of the Autonomic Nervous System

Visceral Effectors	Sympathetic Control	Parasympathetic Control
Heart muscle	Accelerates heartbeat	Slows heartbeat
Smooth Muscle		
Of most blood vessels	Constricts blood vessels	None
Of blood vessels in skeletal muscles	Dilates blood vessels	None
Of the digestive tract	Decreases peristalsis; inhibits defecation	Increases peristalsis
Of the anal sphincter	Stimulates-closes sphincter	Inhibits-opens sphincter for defecation
Of the urinary bladder	Inhibits-relaxes bladder	Stimulates-contracts bladder
Of the urinary sphincters	Stimulates-closes sphincter	Inhibits-opens sphincter for urination
Of the eye:		
Iris	Stimulates radial fibers—dilation of pupil	Stimulates circular fibers—constriction of pupil
Ciliary	Inhibits—accommodation for far vision (flattening of lens)	Stimulates—accommodation for near vision (bulging of lens)
Of hairs (pilomotor muscles)	Stimulates—goose bumps	No parasympathetic fibers
Glands		
Adrenal medulla	Increases epinephrine secretion	None
Sweat glands	Increase sweat secretion	None
Digestive glands	Decrease secretion of digestive juices	Increase secretion of digestive juices

2. **Leukocytes** are white blood cells that do not contain hemoglobin (therefore, they are clear). The several types of leukocytes are involved in guarding the body against invading microorganisms. They also remove dead cells and debris. Some leukocytes are grouped by their appearance. This is based on the presence or absence of cytoplasmic granules. The classifications include neutrophils, eosinophils, and basophils. Other types of leukocytes are nongranular. These leukocytes are named according to nuclear morphology and major site of proliferation. These include lymphocytes and monocytes.
   - **Neutrophils** are the most common type of leukocyte in the blood. These cells normally remain in the circulation for 10 to 12 hours. They then move into tissue to seek out and destroy bacteria and other foreign matter **(phagocytosis)**. Neutrophils also

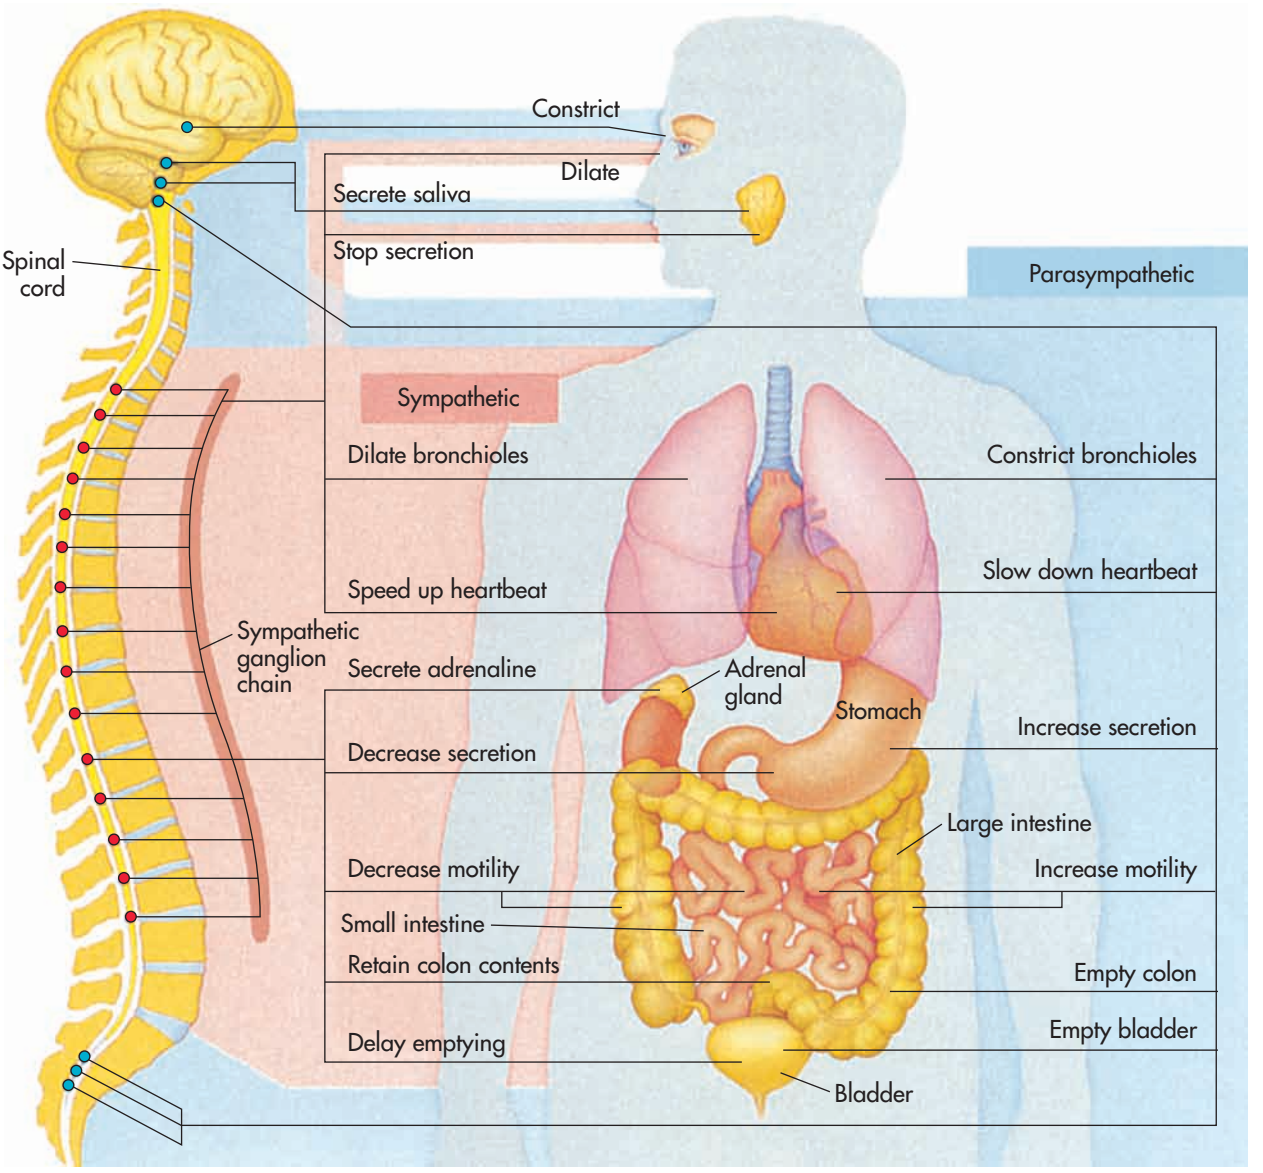

FIGURE 10-37 Innervation of major target organs by the autonomic nervous system. The sympathetic fibers are highlighted in red, and the parasympathetic fibers are highlighted in blue. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

secrete lysosomes that can destroy certain bacteria. Neutrophils usually survive for 1 to 2 days after leaving the circulation.

- **Eosinophils** leave the circulation to enter the tissues during an inflammatory reaction. Their numbers usually are elevated in the blood of individuals with allergies and certain parasitic infections. These cells have phagocytic properties. However, they are not thought to be as important in this function as neutrophils.
- **Basophils** are the least common of all leukocytes. They also are called mast cells when in tissues. Like eosinophils, basophils leave the circulation and migrate through tissues to play a role in allergic and inflammatory reactions. In addition, they release *heparin*, which inhibits blood clotting. They also release **histamine**, which is important to the **inflammatory response** (see Chapter 2).
- **Lymphocytes** are the smallest of all leukocytes. They are capable of migrating through the cytoplasm of other cells. The many different types of lymphocytes play a major role in immunity, including antibody production. Lymphocytes originate in bone marrow. They are most abundant in lymphoid tissues; that is, the **lymph nodes**, **spleen**, **tonsils**, **lymph nodules**, and **thymus**.
- **Monocytes** are the largest of the leukocytes. They remain in the circulation for about 3 days before changing into **macrophages**. These large "eating" cells migrate through various tissues. An increase in

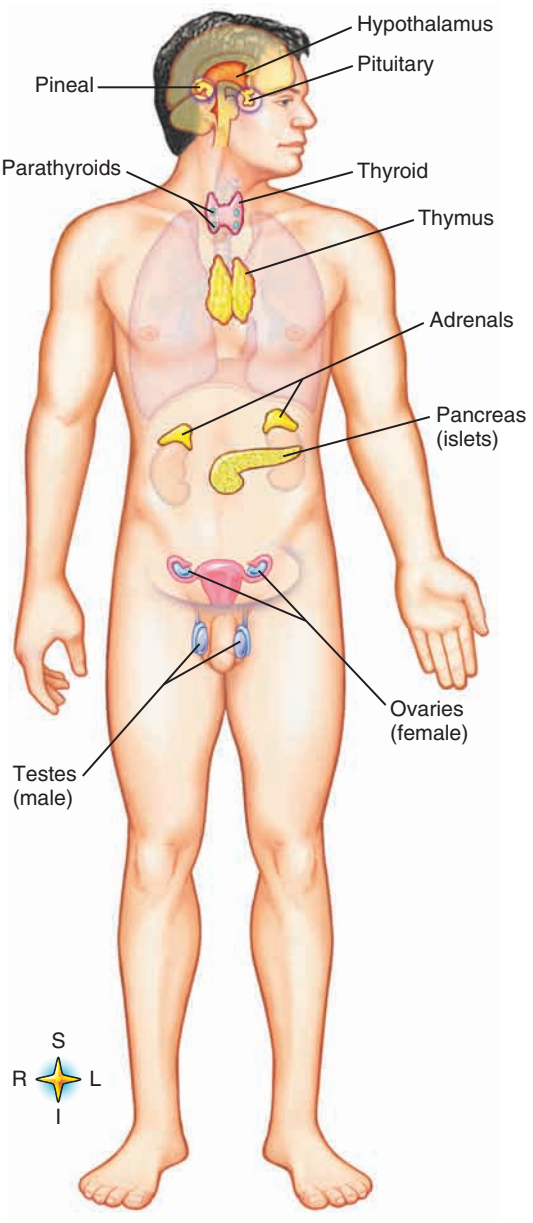

FIGURE 10-38 Locations of major endocrine glands. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

the number of monocytes is common in patients with chronic infections.

3. **Platelets** are produced in bone marrow. They are 40 times as common in blood as leukocytes. Platelets play a key role in preventing blood loss by forming plugs that seal holes in small vessels and by forming clots that seal off larger wounds in the vessels.

CARDIOVASCULAR SYSTEM

The heart and cardiovascular system are responsible for circulating blood throughout the body. (The cardiovascular system is discussed in detail in Chapter 22.)

Anatomy of the Heart. The heart is a muscular pump consisting of four chambers, two **atria** and two **ventricles**. The adult heart is shaped like a blunt cone and is about the size of a closed fist. The heart is located in the mediastinum of the thoracic cavity in the pericardial cavity. The blunt, rounded point of the heart is the *apex*, and the larger, flat portion at the opposite end is the *base*.

The heart lies obliquely in the mediastinum. The base is directed posteriorly and slightly superiorly. The apex is directed anteriorly and slightly inferiorly. Two thirds of the mass of the heart lies to the left of the midline of the sternum (Figures 10-39 and 10-40).

Pericardium. The pericardium is also known as the **pericardial sac**. The pericardium has a fibrous outer layer and a thin inner layer that surrounds the heart. These layers are the *fibrous pericardium* and the *serous pericardium*, respectively. The portion of the serous pericardium that lines the fibrous pericardium is the *parietal pericardium*. The portion that covers the heart surface is the *visceral pericardium* or the **epicardium**. The cavity between the parietal pericardium and the visceral pericardium normally contains a small amount of *pericardial fluid*. This fluid reduces friction as the heart moves within the pericardial sac.

CRITICAL THINKING

Why would a sudden increase in the amount of pericardial fluid be harmful?

TABLE 10-9 Endocrine Glands, Hormones, and Their Functions

Gland/Hormone	Function
Anterior Pituitary	
Thyroid-stimulating hormone	Tropic hormone; stimulates secretion of thyroid hormones
Adrenocorticotropic hormone	Tropic hormone; stimulates secretion of adrenal cortex hormones
Follicle-stimulating hormone	Tropic hormone *Female:* Stimulates development of ovarian follicles and secretion of estrogens *Male:* Stimulates seminiferous tubules of testes to grow and produce sperm
Luteinizing hormone	Tropic hormone *Female:* Stimulates maturation of ovarian follicle and ovum; stimulates secretion of estrogen; triggers ovulation; stimulates development of corpus luteum (luteinization) *Male:* Stimulates interstitial cells of the testes to secrete testosterone

TABLE 10-9 Endocrine Glands, Hormones, and Their Functions—cont'd

Gland/Hormone	Function
Melanocyte-stimulating hormone	Stimulates synthesis and dispersion of melanin pigment in the skin
Growth hormone	Stimulates growth in all organs; mobilizes food molecules, causing an increase in blood glucose concentration
Prolactin (lactogenic hormone)	Stimulates breast development during pregnancy and milk secretion after pregnancy
Posterior Pituitary*	
Antidiuretic hormone	Stimulates retention of water by the kidneys
Oxytocin	Stimulates uterine contractions at the end of pregnancy; stimulates the release of milk into the breast ducts
Hypothalamus	
Releasing hormones (several)	Stimulate the anterior pituitary to release hormones
Inhibiting hormones (several)	Inhibit secretion of hormones by the anterior pituitary
Thyroid	
Thyroxine, triiodothyronine	Stimulate the energy metabolism of all cells
Calcitonin	Inhibits the breakdown of bone; causes a decrease in blood calcium concentration
Parathyroid	
Parathyroid hormone	Stimulates the breakdown of bone; causes an increase in blood calcium concentration
Adrenal Cortex	
Mineralocorticoids: aldosterone	Regulate electrolyte and fluid homeostasis
Glucocorticoids: cortisol (hydrocortisone)	Stimulate gluconeogenesis, causing an increase in blood glucose concentration; also have antiinflammatory, antiimmunity, and antiallergy effects
Sex hormones (androgens)	Stimulate sexual drive in the female but have negligible effects in the male
Adrenal Medulla	
Epinephrine (adrenaline), norepinephrine	Prolong and intensify the sympathetic nervous response during stress
Pancreatic Islets	
Glucagon	Stimulates liver glycogenolysis, causing an increase in blood glucose concentration
Insulin	Promotes glucose entry into all cells, causing a decrease in blood glucose concentration
Ovary	
Estrogens	Promotes development and maintenance of female sexual characteristics
Progesterone	Promotes conditions required for pregnancy
Testis	
Testosterone	Promotes development and maintenance of male sexual characteristics
Thymus	
Thymosin	Promotes development of immune-system cells
Placenta	
Chorionic gonadotropin, estrogens, progesterone	Promote conditions required during early pregnancy
Pineal	
Melatonin	Inhibits tropic hormones that affect the ovaries; may be involved with the internal clock of the body
Heart (atria)	
Atrial natriuretic hormone	Regulates fluid and electrolyte homeostasis

*Posterior pituitary hormones are synthesized in the hypothalamus but are released from axon terminals in the posterior pituitary.

TABLE 10-10 Classes of Blood Cells

Cell Type	Function
Erythrocyte	Oxygen and carbon dioxide transport
Neutrophil	Immune defenses (phagocytosis)
Eosinophil	Defense against parasites
Basophil	Inflammatory response
B lymphocyte	Antibody production (precursor of plasma cells)
T lymphocyte	Cellular immune response
Monocyte	Immune defenses (phagocytosis)
Platelet	Blood clotting

Coronary Vessels. Seven large veins normally carry blood to the heart: four **pulmonary veins** carry blood from the lungs to the left atrium; the **superior vena cava** and **inferior vena cava** carry blood from the body to the right atrium; and the coronary sinus carries blood from the walls of the heart to the right atrium. Two arteries, the aorta and the pulmonary trunk, exit the heart. The **aorta** carries blood from the left ventricle to the body. The **pulmonary trunk** carries blood from the right ventricle to the lungs. The right and left **coronary arteries** exit the aorta near the point where the aorta leaves the heart. They supply the heart muscle with oxygen and nutrients (Figure 10-41).

Heart Chambers and Valves. The right and left chambers of the heart are separated by a **septum**. The *interatrial septum* separates the **right atrium** and the **left atrium**. The *interventricular septum* separates the two ventricles. The atria open into the ventricles through the *atrioventricular canals*. An **atrioventricular valve** on each atrioventricular canal is composed of cusps or flaps. These valves allow blood to flow from the atria into the ventricles. Yet they prevent blood from flowing back into the atria. The atrioventricular valve between the right atrium and right ventricle has three cusps; it is called the **tricuspid valve**. The atrioventricular valve between the left atrium and left ventricle has two cusps and is called the **bicuspid valve** (or *mitral valve*).

The aorta and pulmonary trunk possess *aortic and pulmonary semilunar valves*. These valves meet in the center of the artery to block blood flow. Blood flowing out of the ventricles pushes against each valve, forcing it open. However, when blood flows back from the aorta or pulmonary trunk toward the ventricles, the valves close.

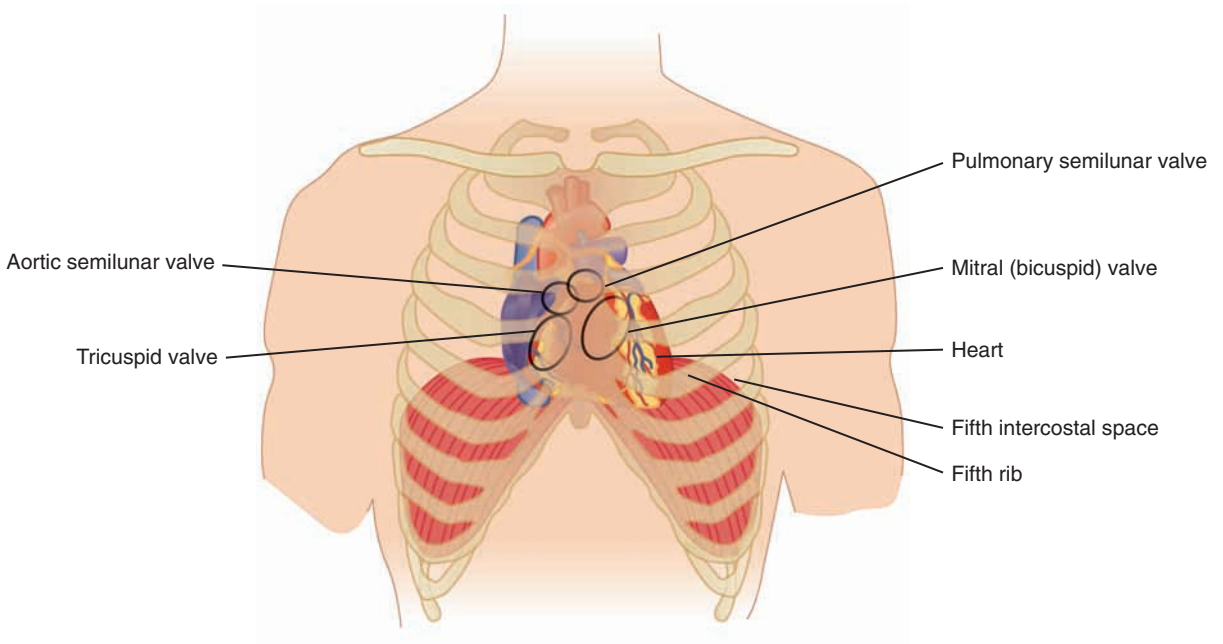

FIGURE 10-39 Location of the heart in the thorax.

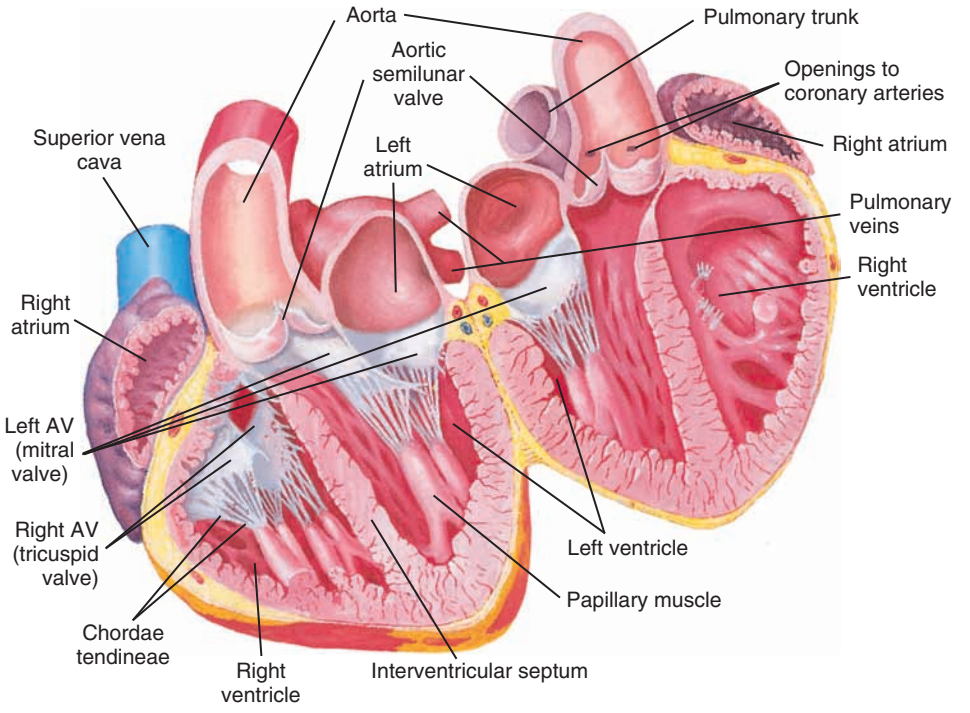

FIGURE 10-40 Internal view of the heart. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

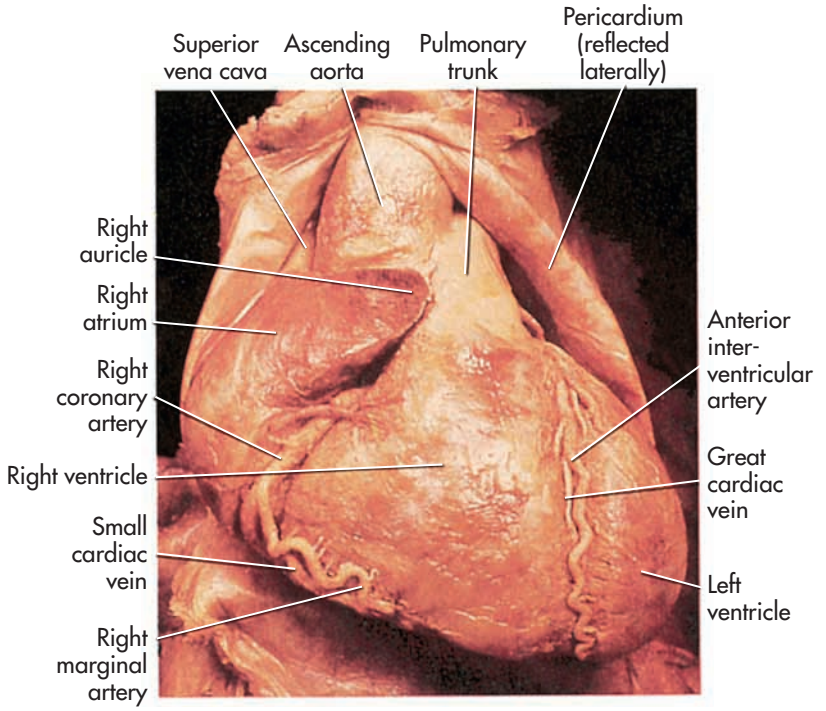

FIGURE 10-41 Anterior surface of the heart.

Conduction System of the Heart. The muscle tissue of the heart has the unique ability for spontaneous, rhythmic self-excitation. This excitation occurs by way of four structures embedded in the wall of the heart. These structures are the **sinoatrial node**, the **atrioventricular node**, the **bundle of His**, and the **Purkinje fibers** (Figure 10-42).

Impulse conduction normally begins in the sinoatrial node. From there the impulse spreads in all directions through both of the atria, causing an atrial contraction. As the electrical impulses reach the atrioventricular node, they are relayed to the ventricles through the bundle of His and the Purkinje fibers. This impulse conduction causes both

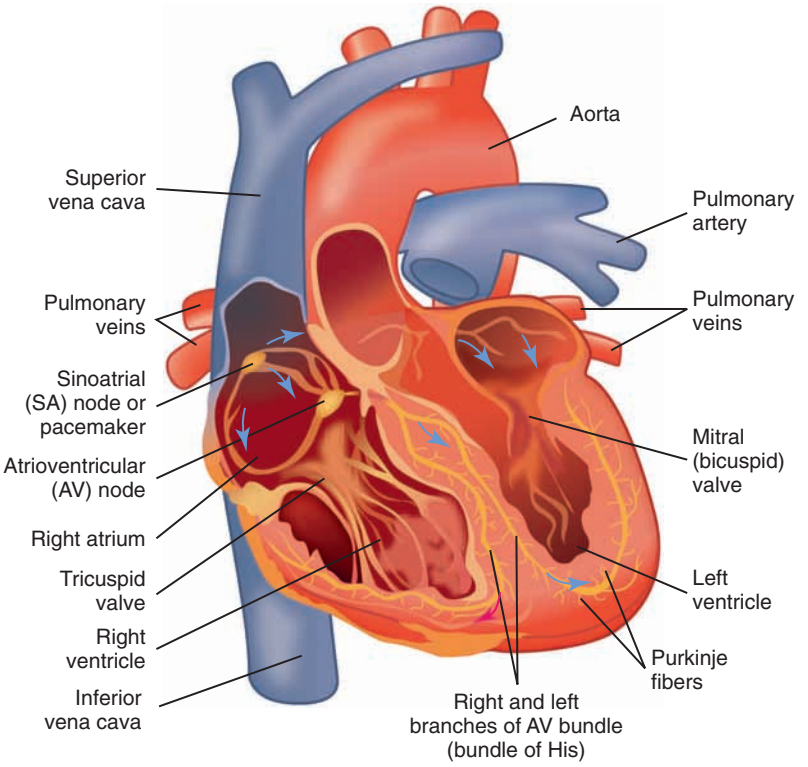

FIGURE 10-42 Conduction system of the heart.

of the ventricles to contract shortly after the atrial contraction.

Route of Blood Flow Through the Heart. This text presents blood flow through the heart with a discussion of right and left heart circulation (Figure 10-43). It is important to remember that both atria contract at the same time. This contraction is followed shortly thereafter by essentially simultaneous contraction of both ventricles.[4] Knowing this is key to understanding clearly the electrical impulses of the heart, pressure changes, and heart sounds that are discussed in other chapters.

Blood enters the right atrium from the systemic circulation via the inferior and superior venae cavae. Blood enters from the heart muscle via the coronary sinus. Most of this blood passes into the right ventricle as the ventricle relaxes after the previous contraction. When the right atrium contracts, the blood left in the atrium is pushed into the ventricle. The contraction of the right ventricle pushes blood against the tricuspid valve, forcing it closed. The contraction also pushes blood against the *pulmonary semilunar valve*, forcing the valve open. This flow allows blood to enter the pulmonary trunk. The pulmonary trunk divides into left and right pulmonary arteries that carry blood to the lungs. In the lungs the blood releases carbon dioxide and picks up oxygen.

CRITICAL THINKING

A clot forms in the right atrium of the heart. Will it be circulated to the extremities? Why?

Blood returning from the lungs enters the left atrium through four pulmonary veins. The blood passing from the left atrium to the relaxed left ventricle opens the bicuspid valve. The contraction of the left atrium completes the filling of the left ventricle.

Contraction of the left ventricle pushes blood against the bicuspid valve, closing the valve. The pressure of the blood against the aortic semilunar valve causes it to open. This allows blood to enter the aorta. Blood flowing through the aorta is distributed to all parts of the body except for the pulmonary vessels in the lungs.

PERIPHERAL CIRCULATION

Blood is pumped from the ventricles of the heart into large elastic arteries. These arteries branch repeatedly to form many gradually smaller arteries. As these vessels become smaller, the amount of elastic tissue in the arterial wall decreases. At the same time, the amount of smooth muscle increases.

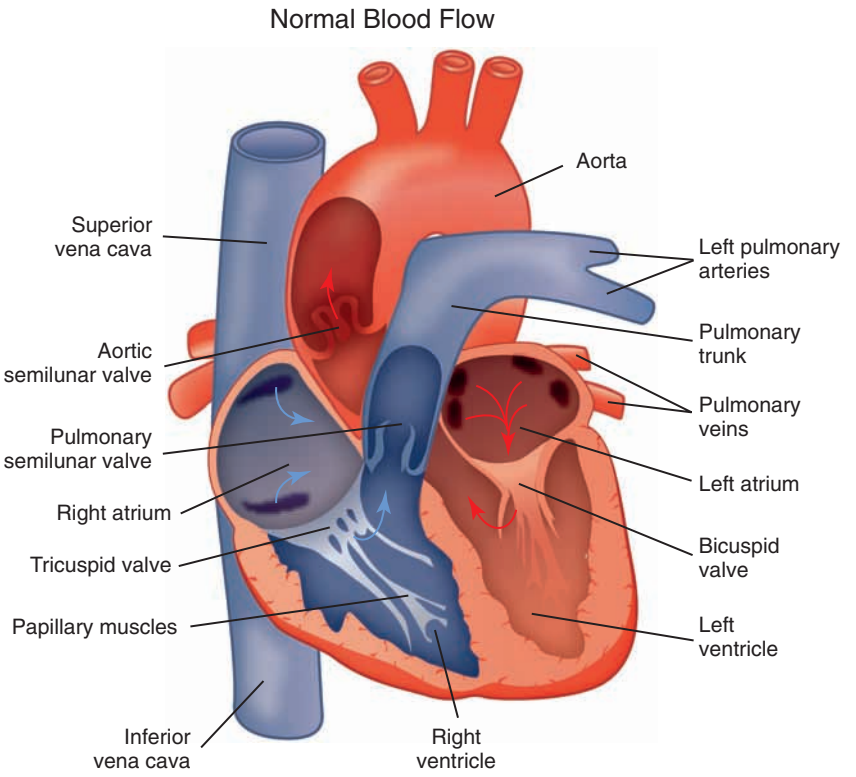

FIGURE 10-43 Frontal section of the heart showing the four chambers and the direction of blood flow through the heart.

Blood flows from the **arterioles** into **capillaries** and from capillaries into the venous system. Compared with artery walls, vein walls are thinner and contain less elastic tissue and fewer smooth muscle cells. As veins approach the heart, the walls increase in diameter and thickness.

Capillary Network. Arterioles supply blood to each capillary network (Figure 10-44). Blood flows through this network and into the venules. The ends of the capillaries closest to arterioles are *arterial capillaries*. The ends closest to venules are *venous capillaries*.

Blood flow through arterioles may continue through *metarterioles* and into a *thoroughfare channel* to a venule in a relatively constant way; or, blood may enter the *capillary circulation*. Flow in the capillaries is regulated by smooth muscle cells. These cells are known as **precapillary sphincters**. The exchange of nutrients and waste products is the major role of the capillaries.

Arteries and Veins. Blood vessel walls are made up of three layers of elastic tissue and smooth muscle. (Capillaries and venules are the exception.) These layers also are known as **tunics**. The layers are the *tunica intima* (inner layer), the *tunica media* (middle layer), and the *tunica adventitia* (outer layer). The thickness and composition of each layer vary with the type and diameter of the blood vessel.

Large elastic arteries often are called *conducting arteries,* because they are the arteries with the largest diameter. These vessels have more elastic tissue and less smooth muscle than any other arteries. Medium and small arteries have fairly thick muscular walls. These arteries also have elastic membranes that are well developed. These vessels are called distributing arteries because the smooth muscle allows these vessels partially to regulate blood supply to various body regions. The vessels do this by constriction or dilation. Arterioles are the smallest arteries in which the three tunics can be detected. As do small arteries, arterioles can vasodilate and vasoconstrict.

Venules have only a few isolated smooth muscle cells and are similar in structure to the capillaries. Venules collect blood from the capillaries and transport it to small veins. These veins in turn transport the blood to the medium-sized veins. Nutrient exchange occurs across the walls of the venules, but as the small veins increase in thickness, the degree of nutrient exchange decreases.

As venules increase in diameter, the vessels become veins with walls that are a continuous layer of smooth muscle cells. Medium-sized and large veins collect blood from small veins and deliver it to the large venous trunks. Large veins transport blood from the medium-sized veins to the heart.

Veins with a large diameter have valves that allow blood to flow to but not from the heart. Medium-sized veins have many valves, and the veins of the lower extremities have

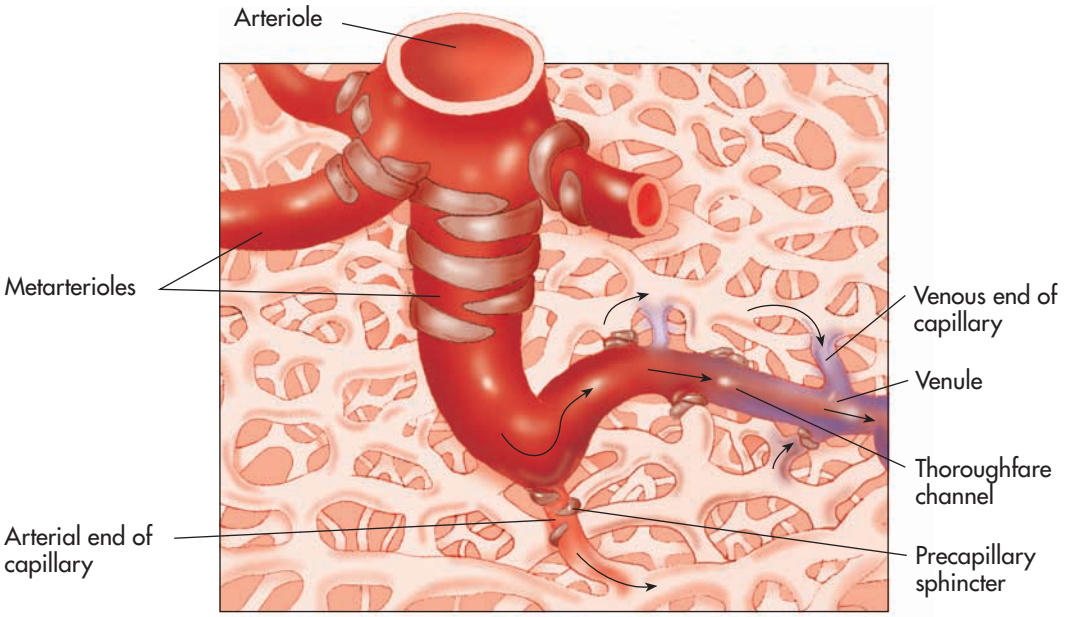

FIGURE 10-44 Capillary network. The metarteriole, giving rise to the network, feeds directly from the arteriole into the thoroughfare channel, which feeds into the venule. The network forms numerous branches that transport blood from the thoroughfare channel and may return to the thoroughfare channel.

more valves than do those of the upper extremities. These valves help prevent the backflow of blood, especially in dependent tissues.

Arteriovenous anastomoses allow blood to flow from arteries to veins without passing through capillaries. Natural *arteriovenous shunts* occur in large numbers in the soles of the feet, palms, and nail beds, where they regulate body temperature. Pathological shunts can result from injury or tumors. These shunts can cause a direct flow of blood from arteries to veins. Severe shunts may lead to "high output" heart failure from increased venous return to the heart and its resultant demand on **cardiac output** (see Chapter 22).

PULMONARY CIRCULATION

Blood from the right ventricle is pumped into the pulmonary trunk. This trunk splits into the right and left pulmonary arteries. These arteries move blood to the respective lungs, where oxygen and carbon dioxide are exchanged. Two pulmonary veins exit each lung and enter the left atrium. Pulmonary veins are the only veins in the body that carry oxygenated blood. Pulmonary arteries are the only arteries in the body that carry deoxygenated blood.

SYSTEMIC CIRCULATION

Oxygenated blood enters the heart from the pulmonary veins. The blood passes through the left atrium into the left ventricle. Then the blood passes from the left ventricle into the aorta. From the aorta, blood is distributed to all parts of the body. The arteries of systemic circulation include the aorta, coronary arteries, arteries of the head and neck, arteries of the upper and lower limbs, the thoracic aorta and its branches, the **abdominal aorta** and its branches, and the arteries of the pelvis (Figure 10-45).

The veins of systemic circulation include coronary veins, veins of the head and neck, veins of the upper and lower limbs, veins of the thorax, veins of the abdomen and pelvis, and the *hepatic portal system*, which transports blood from the digestive tract to the liver (Figure 10-46).

Lymphatic System

The **lymphatic system** is considered part of the circulatory system because it consists of a moving fluid that comes from the body and returns to the blood. Unlike the circulatory system, the lymphatic system only carries fluid away from the tissues.

As stated before, the lymphatic system includes lymph, lymphocytes, lymph nodes, tonsils, spleen, and the thymus gland. The lymphatic system has three basic functions: (1) to help maintain fluid balance in tissues; (2) to absorb fats and other substances from the digestive tract; and (3) to act as part of the body's immune defense system.

The lymphatic system begins in the tissues as *lymph capillaries*. These capillaries differ in structure from blood capillaries. Lymph capillaries have a series of one-way valves. These valves allow fluid to enter the capillary. However, the valves prevent fluid from passing back into the interstitial spaces. Almost all body tissues have lymph capillaries; the exceptions are the CNS, bone marrow, and tissues without blood vessels (e.g., cartilage, epidermis, and cornea). Lymph capillaries join to form larger lymph capillaries that resemble small veins.

Lymph nodes are distributed along various lymph vessels. Most lymph passes through at least one node before

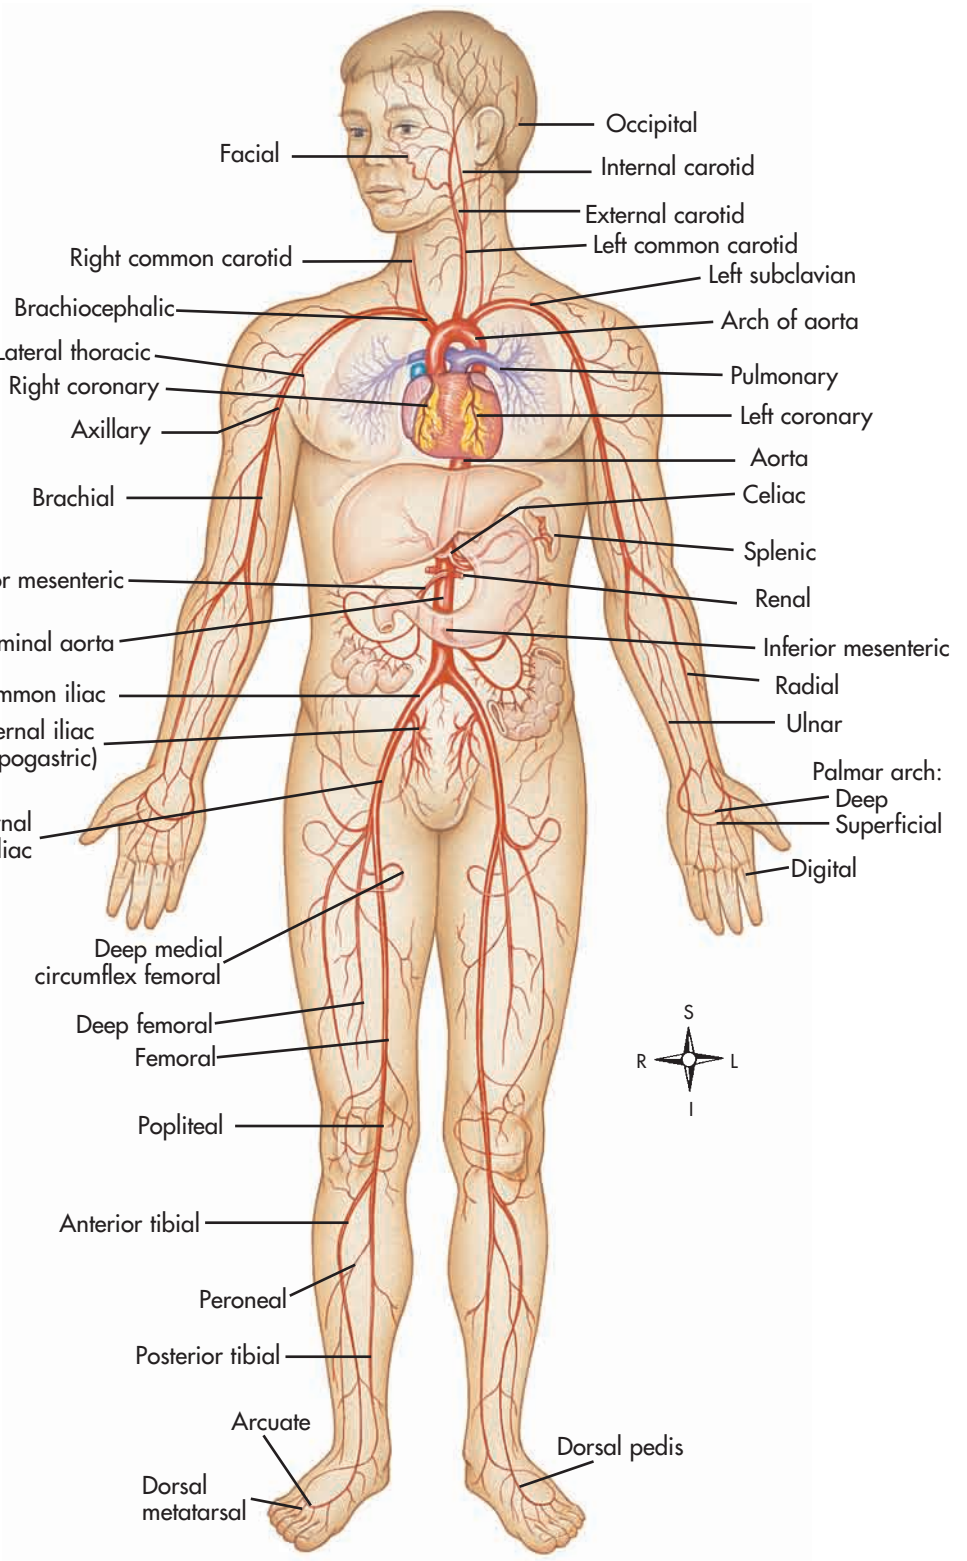

FIGURE 10-45 Principal arteries of the body. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

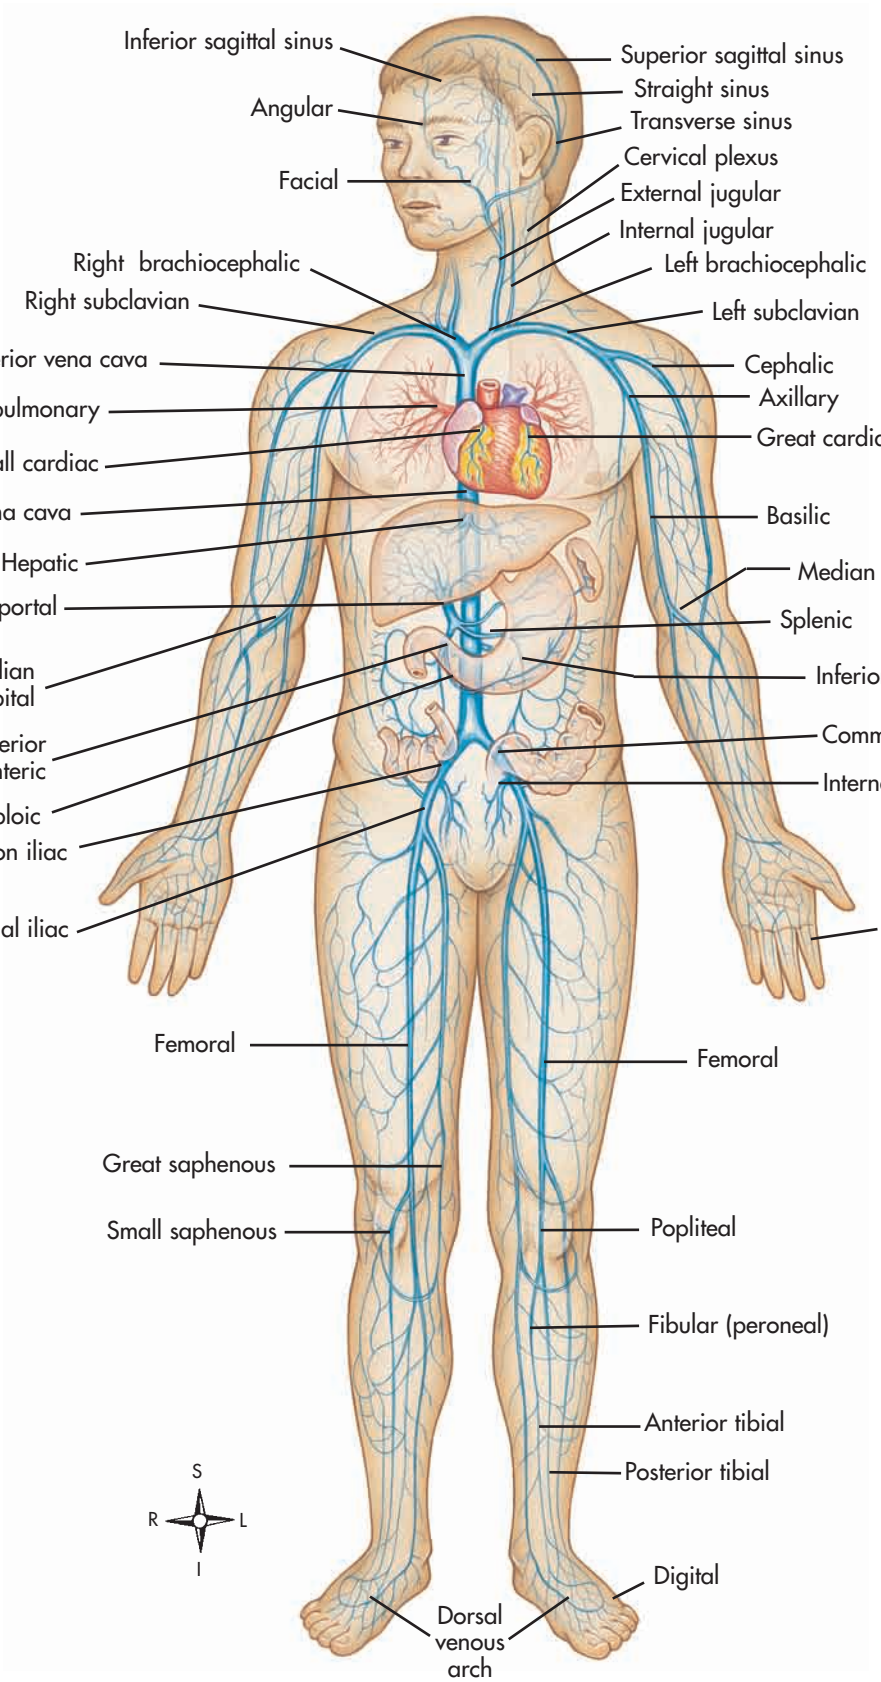

FIGURE 10-46 Principal veins of the body. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

entering the blood. The node filters the lymph as it passes through the node. Filtering removes microorganisms and foreign substances, preventing them from entering the general circulation. Three major collections of lymph nodes are located on each side of the body: *inguinal nodes, axillary nodes,* and *cervical nodes*. If a part of the body is inflamed or otherwise diseased, the nearby lymph nodes become swollen and tender as they limit the spread of microorganisms and foreign substances.

After passing through lymph nodes, lymph vessels converge toward the right or left **subclavian vein**. Vessels from the upper right limb and the right side of the head enter the right lymphatic duct. Lymph vessels from the rest of the body enter the larger thoracic duct. The *right lymphatic duct* drains the right thorax, right upper limb, and right side of the head and neck and opens into the right subclavian vein. The *thoracic duct* drains the left thorax, the left upper extremity, and the left side of the head and neck. The duct ends by entering the left subclavian vein. All fluid drained from the tissue spaces eventually returns to the venous circulation.

Lymph serves a unique transport role. It returns tissue fluid, proteins, fats, and other substances to the general circulation. The lymphatic system does not form a closed ring or circuit, as does the true circulatory system. Once lymph has formed, it flows only once through its system of lymphatic vessels before draining into the right and left subclavian veins.

CRITICAL THINKING

A woman has had a radical mastectomy (removal of breast and lymph tissue). Why might she have a chronically swollen arm?

Respiratory System

Oxygen is a basic element needed for normal cell metabolism. Carbon dioxide is a major waste product of this process. The organs of the respiratory system and the cardiovascular system transport oxygen to individual cells. These organs then transport carbon dioxide from the cells to the lungs. In the lungs the carbon dioxide is released into the air.

The respiratory system is a complex part of the human body. The aim of this section is to familiarize the paramedic student with the respiratory anatomy. (Further discussion of the respiratory system is presented in Chapter 15.)

AIRWAY ANATOMY

The structures of the respiratory system are divided into the upper airway and the lower airway. They are divided by their locations relative to **the glottic opening** (i.e., the vocal cords and the space between them). For the purpose of this text, all airway structures above the glottis are considered to be *upper airway*. All structures below the glottis are considered to be *lower airway* (Figure 10-47).

UPPER AIRWAY STRUCTURES

The entrance to the respiratory tract begins with the nasal cavity. This cavity includes the nasopharynx, oropharynx, laryngopharynx, and larynx.

Nasopharynx. Air passes into the nasal cavity through the nostrils, or *nares*. The right and left nasal cavities are separated by the *nasal septum,* a bony partition covered with a mucous membrane. This membrane has a rich blood supply that warms and humidifies the nasal lining and the inspired air as it passes through the nose. Inside each nostril a slight enlargement, known as the *vestibule,* is lined with coarse hairs that trap foreign substances carried into the nasal cavity by inspired air. The floor of the nasal cavity is composed of the *hard palate;* the lateral walls are formed by bony ridges coated with respiratory mucosa. These ridges are known as *conchae*, or *turbinates*.

Two patches of yellow-gray tissue lie just beneath the bridge of the nose. These patches compose the *olfactory membranes*. Located in the roof of the nasal cavity, these membranes contain the receptors for the sense of smell. The nasal cavities also connect to the middle ear cavities through the auditory (or eustachian) tubes.

CRITICAL THINKING

Why might a chronic cocaine abuser have a higher risk of sinus infection?

Sinuses are cavities in the bones of the skull that connect to the nasal cavities by small channels (Figure 10-48). The four groups of sinuses, each named for the skull bone in which it lies, are the *frontal sinuses,* above the eyebrows; *maxillary sinuses* (the largest sinuses), in the cheekbones; *ethmoid sinuses,* just behind the bridge of the nose; and *sphenoid sinuses,* in a bone that cradles the brain, slightly anterior to the **pituitary gland**. These hollow chambers are lined with mucous membranes that secrete mucus into the nasal cavities. They are thought to help add resonance to the voice and to reduce the weight of the skull.

The back of each nasal cavity opens into the nasopharynx. This is the superior part of the pharynx. The nasopharynx extends from the internal nares to the level of the **uvula**. Like the nasal cavity, the nasopharynx is lined with mucous membrane.

Oropharynx. At the level of the uvula, the nasopharynx ends and the oropharynx begins. The oropharynx extends down to the level of the **epiglottis**. Anteriorly, the oropharynx opens into the oral cavity. The oral cavity is made up of the lips, cheeks, teeth, tongue (which is attached to the mandible), hard and soft palates, and palatine tonsils. The *palatine tonsils* and the *pharyngeal tonsils* (located in the roof and posterior wall of the nasopharynx) form a partial ring of lymphoid tissue. This tissue surrounds the respiratory tract. This ring is completed by the *lingual tonsils*. The tonsils lie on the floor of the oropharyngeal passageway at the base of the tongue.

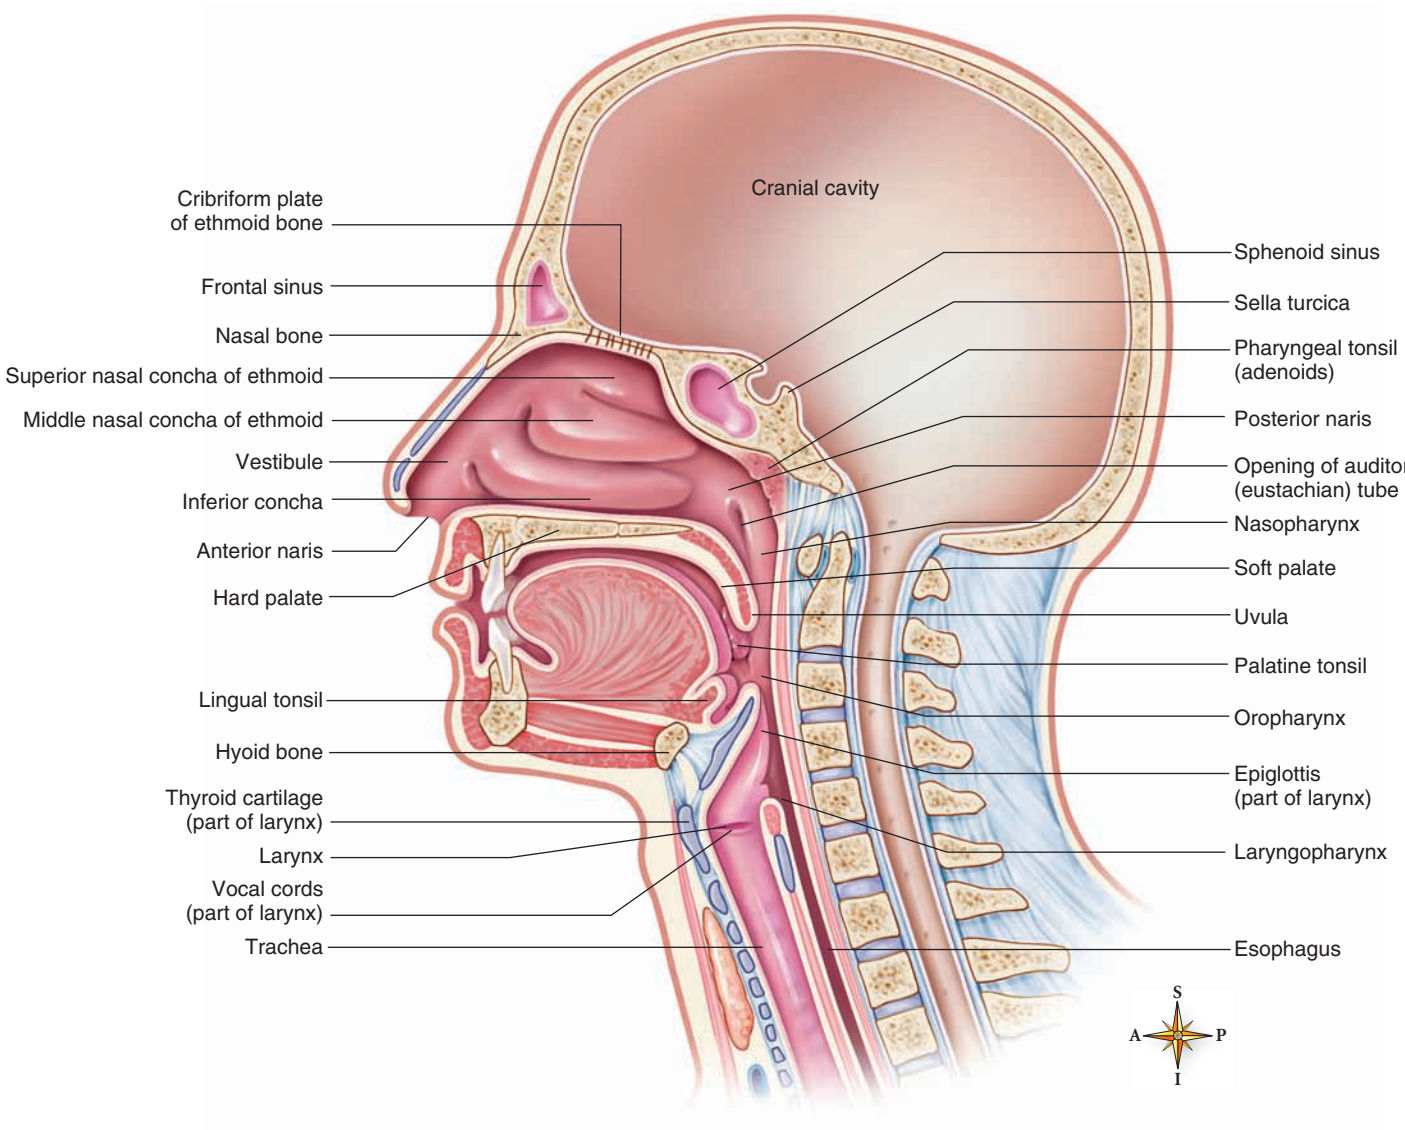

FIGURE 10-47 Airway structures. (Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 7, St Louis, 2007, Mosby.)

Laryngopharynx. The **laryngopharynx** extends from the tip of the epiglottis to the glottis and the **esophagus**. It is lined with mucous membrane, which protects the internal surfaces from abrasion.

Larynx. The laryngopharynx opens into the **larynx**, which lies in the anterior neck (Figure 10-49). The larynx serves three main functions: (1) it is the air passageway between the pharynx and the lungs; (2) it is a protective sphincter that prevents solids and liquids from passing into the respiratory tree; and (3) it is involved in the production of speech.

The larynx consists of an outer casing of nine cartilages connected to each other by muscles and ligaments. Six of the nine cartilages are paired; three are unpaired. The largest, most superior of the cartilages is the unpaired thyroid cartilage, or *Adam's apple*. This prominence is hardly visible in children or adult females but is visible in males after puberty.

The most inferior cartilage of the larynx is the unpaired **cricoid cartilage**. This is the only complete cartilaginous ring in the larynx. This cartilage forms the base of the larynx on which all other cartilages rest. The third unpaired cartilage is the epiglottis.

The six paired cartilages are stacked in two pillars between the cricoid cartilage and the thyroid cartilage. The largest inferior cartilages are ladle-shaped and are known as the *arytenoid cartilages*. The middle pair are horn-shaped and are known as *corniculate cartilages*. The smallest, most superior cartilages are wedge-shaped and are known as *cuneiform cartilages*.

The U-shaped hyoid bone is tucked beneath the mandible. As previously mentioned, the hyoid is the only bone

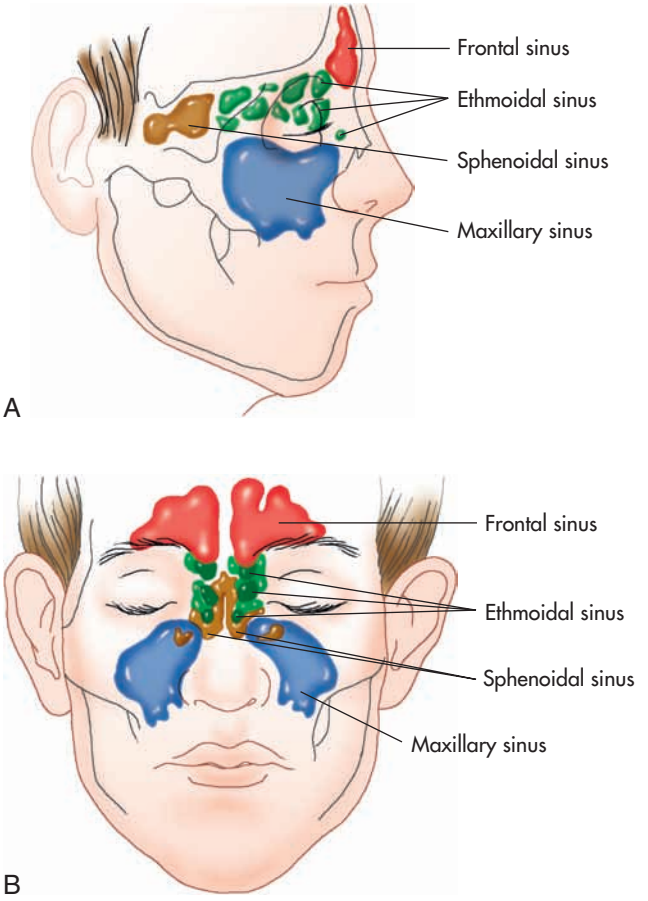

FIGURE 10-48 Paranasal sinuses. **A,** Side view. **B,** Front view.

of the human body that does not articulate with another bone. The hyoid bone helps to suspend the airway by anchoring the muscles (particularly those of the tongue) to the jaw. The fibrous membrane that joins the hyoid and the thyroid cartilage is called the **thyroid membrane**. The membrane joining the thyroid and cricoid cartilages is called the **cricothyroid membrane**.

Two pairs of ligaments extend from the anterior surface of the arytenoid to the posterior surface of the thyroid cartilage. The superior pair forms the *vestibular folds,* or false vocal cords, which are not involved directly in the production of voice sounds. The inferior pair of ligaments composes the **vocal cords**, or true vocal cords, which participate directly in the production of voice sounds. When a person talks, air expelled from the lungs rushes up the throat to the larynx. In the larynx, the air creates sound by vibrating the vocal cords. Muscles tighten the folds of the cords to produce the high-pitched tones and relax the cords to produce the deeper tones. The lips, tongue, and jaw further modify the sounds into intelligible words.

CRITICAL THINKING
Why can't a person talk when an endotracheal tube is correctly positioned in the trachea?

LOWER AIRWAY STRUCTURES

Below the glottis are the structures of the lower airway and lungs. These structures include the trachea, the bronchial tree (primary bronchi, secondary bronchi, and bronchioles), the alveoli, and the lungs (Figure 10-50).

Trachea. The **trachea** is the air passage from the larynx to the lungs. It is composed of dense connective tissue and smooth muscle reinforced with 15 to 20 C-shaped pieces of cartilage that form an incomplete ring. This ring protects the trachea and maintains an open passage for air. The adult trachea is about 1.5 cm in diameter and 9 to 15 cm long. The trachea is located anterior to the esophagus and extends from the larynx to the fifth thoracic vertebra.

The trachea is lined with *ciliated epithelium* that contains many goblet cells. These cilia protect the lower airway. They sweep mucus, bacteria, and other small particles toward the larynx. At the larynx, the mucus and its contents may be expelled through coughing, or they may enter the esophagus, where they are swallowed and digested. Constant exposure to some irritants (e.g., cigarette smoke) may produce a tracheal epithelium that lacks cilia and goblet cells. When this protective mechanism is disrupted, mucus and bacteria may contribute to disease.

NOTE
A centimeter is equal to 0.4 inch. One inch is equal to 2.54 cm.

Bronchial Tree. The lower airway may be thought of as an inverted tree; the many subdivisions become narrower and shorter until they terminate at the alveoli. The large branches are *primary bronchi,* which divide into smaller secondary bronchi and bronchioles.

The trachea divides into the *right* and *left primary bronchi* at the level of the angle of Louis (the **sternomanubrial joint**). The point of bifurcation of the trachea into the right and left mainstem bronchi is called the **carina**. The right primary bronchus is shorter, wider, and more vertical. Like the trachea, the primary bronchi are lined with ciliated epithelium. They are supported by C-shaped cartilage rings. As the bronchi sequentially branch into smaller subdivisions, the amount of cartilage decreases. The bronchi also become more and more muscular until no cartilage is present. The primary bronchi extend from the mediastinum to the lungs.

The primary bronchi divide into the *secondary bronchi* as they enter the right and left lungs. Two secondary lobar bronchi in the left lung conduct air to its two lobes; three in the right lung conduct air to its three lobes. The secondary bronchi then divide into the *tertiary segmental bronchi,* of which there are 10 in the right lung and nine in the left. The tertiary bronchi extend to the individual segments of each lobe of the lung (lobule). The bronchial tree continues to branch several times. As the cartilage continues to decrease and the diameter is reduced to about 1 mm, the bronchi become **bronchioles**.

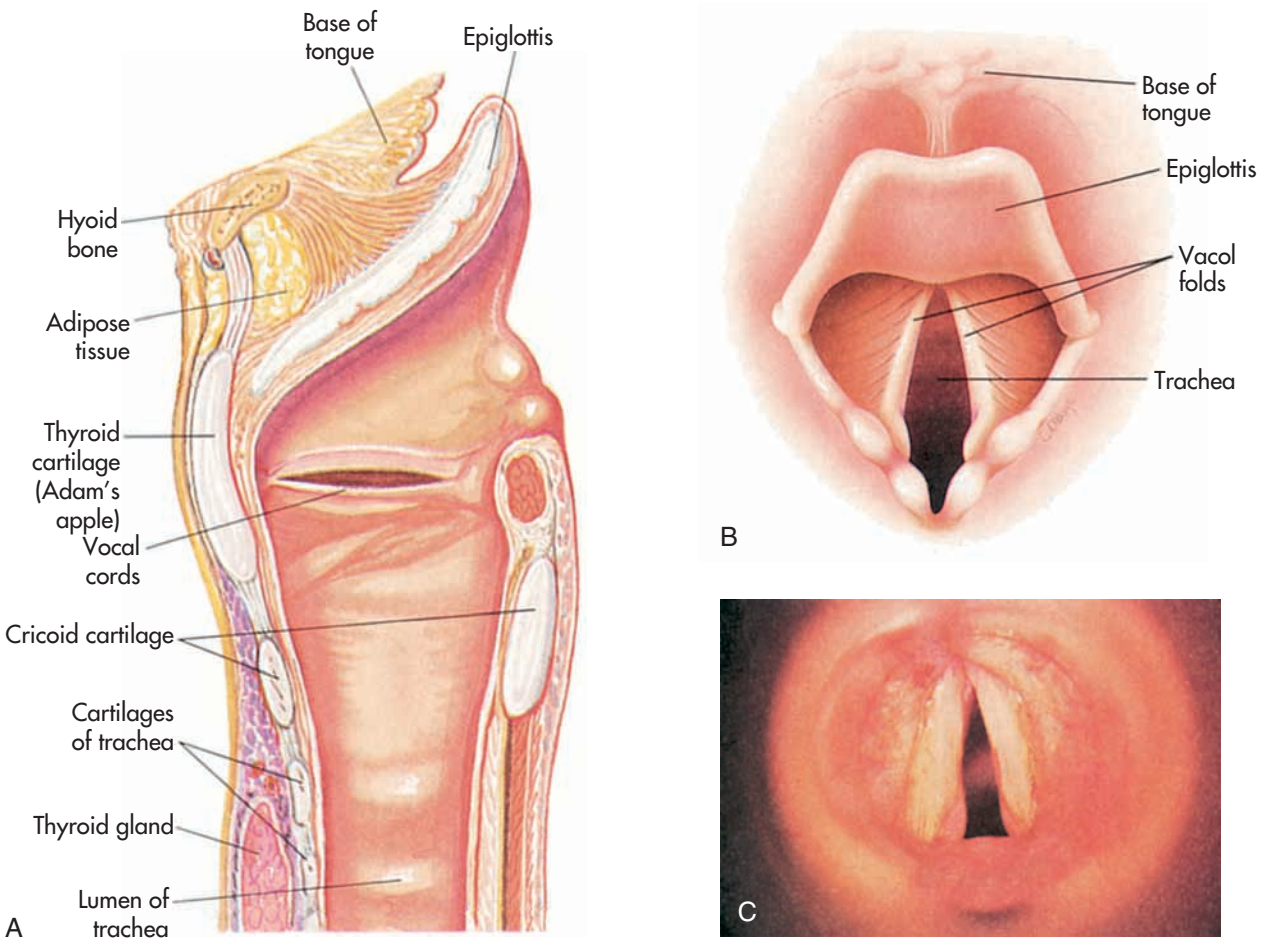

FIGURE 10-49 Larynx. **A,** Sagittal section. **B,** Superior view. **C,** Photograph taken with an endoscope. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

CRITICAL THINKING
What is the benefit of having many bronchiole branches?

NOTE
A millimeter is equal to 0.04 inch. One inch is equal to 25.4 mm.

The walls of the bronchioles are devoid of cartilage. Their muscles are sensitive to certain circulating hormones, such as epinephrine. Contraction and relaxation of these muscles alter resistance to air flow. The bronchioles can constrict if the smooth muscle contracts forcefully. (An example of this is an asthma exacerbation.) Bronchioles continue to divide. In time they become *terminal bronchioles*. Ultimately, they become *respiratory bronchioles*. Each respiratory bronchiole divides to form *alveolar ducts*. These ducts end as grapelike clusters of tiny, hollow air sacs. These sacs are called *alveoli.* Most respiratory gas exchange takes place in the alveoli.

Alveoli. The **alveoli** are the functional units of the respiratory system. They are the main constituent of lung tissue. The two lungs have about 300 million alveoli. The wall of an alveolus consists of a single layer of epithelial cells and elastic fibers. These fibers permit the alveolus to stretch and contract during breathing. The exchange of oxygen and carbon dioxide in the lungs takes place in the alveoli (see Chapter 15).

Each alveolus is surrounded by a fine network of blood capillaries. These capillaries are arranged so that air in the alveolus is separated by a thin respiratory membrane from the blood in the alveolar capillaries. The large surface area of the respiratory membrane may be reduced by respiratory diseases, such as *emphysema* and *lung cancer*. Such diseases restrict the exchange of oxygen and carbon dioxide.

Alveoli are coated with **pulmonary surfactant**, a thin film made by alveolar cells. This fluid keeps the alveoli from collapsing. In addition, pores in the alveolar membrane allow for a limited flow of air between alveoli. This collateral ventilation offers some protection for an alveolus that is occluded by disease.

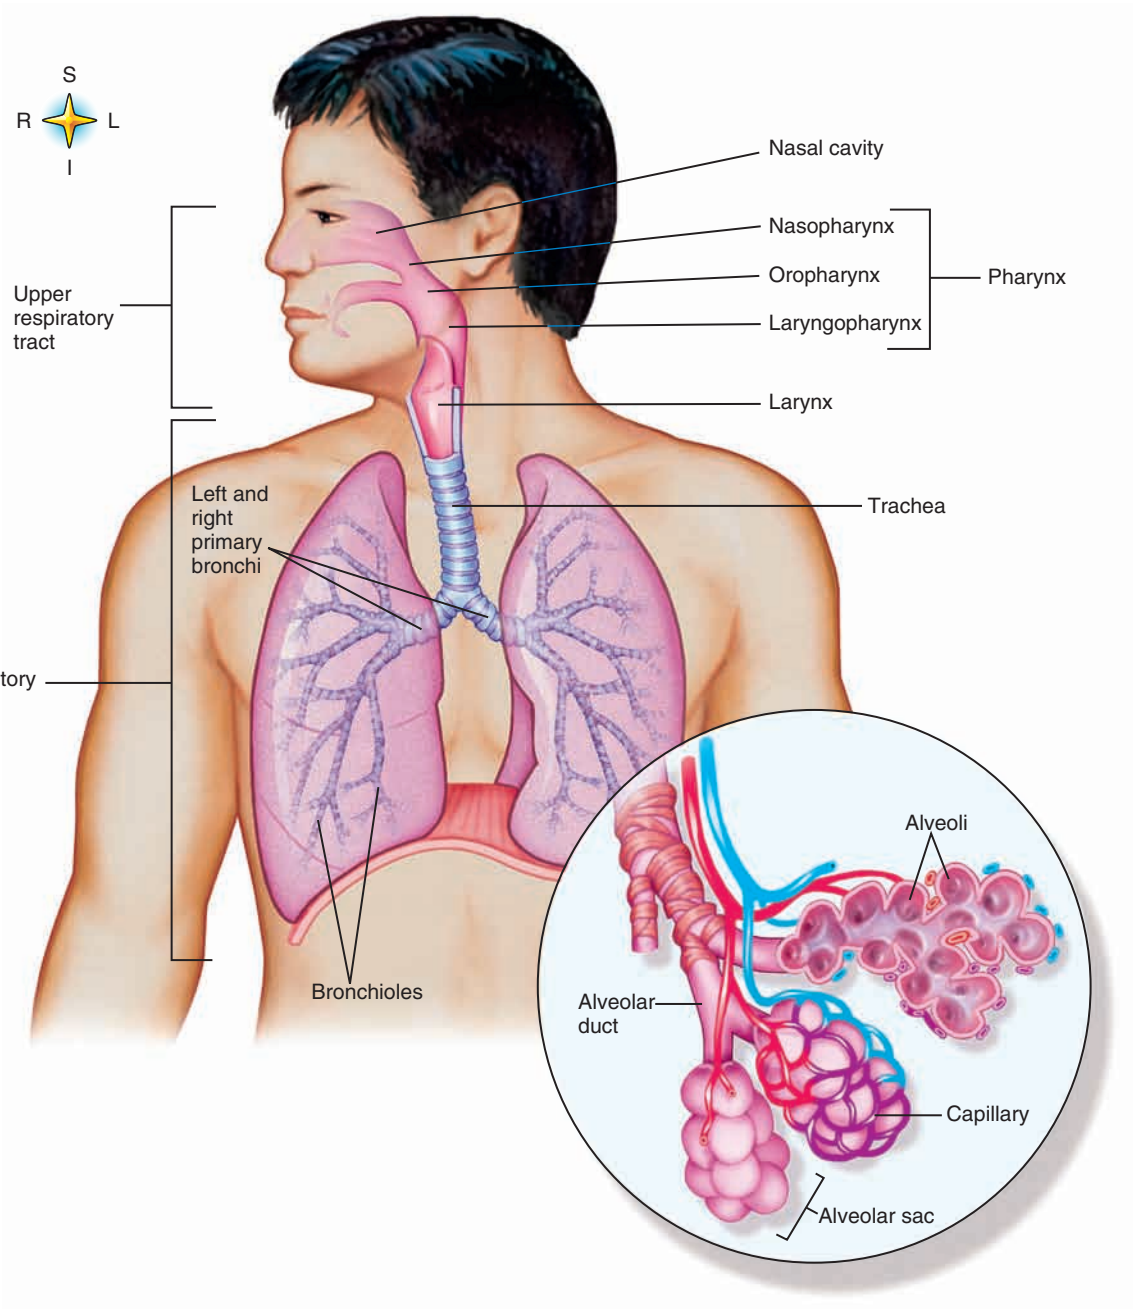

FIGURE 10-50 Structural plan of the respiratory system. The inset shows alveolar sacs; the exchange of oxygen and carbon dioxide takes place through the walls of the grapelike alveoli. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

CRITICAL THINKING

One effect of toxic smoke inhalation is destruction of pulmonary surfactant. Why won't oxygen therapy alone always help? What do you think might help?

Lungs. The lungs are large, paired, spongy organs; their main function is **respiration**. Although smooth muscle is present in the bronchioles of the lungs, the lungs expand and contract during the respiratory cycle as a result of the expansion of the thoracic cavity during inspiration and the elastic recoil during expiration. The lungs are attached to the heart by the pulmonary artery and veins. The two lungs are separated by the mediastinum and its contents (the heart, blood vessels, trachea, esophagus, lymphatic tissues, and vessels). The point of entry for the bronchi, vessels, and nerves of each lung is known as the *hilum*, or root, of each lung. At birth the lungs are rose pink. However, by adulthood the lungs are slate gray with dark patches because of the particulate matter that is inhaled and deposited in the tissues. An adult lung weighs less than 2 pounds.

Each lung is conical, with the base resting on the **diaphragm** and the apex extending to a point about 2.5 cm superior to each clavicle. The right lung is divided into three lobes. The left lung is slightly smaller than the right and is divided into two lobes. Each lobe is divided into lobules separated by connective tissue. Major blood vessels and bronchi do not cross this connective tissue; this allows a diseased lobule to be removed surgically, leaving the remaining lung relatively intact. The left lung has nine lobules, and the right lung has 10 lobules.

Both lungs are surrounded by a separate **pleural cavity**. The lungs are attached to each other only at the point of entry of the bronchi, vessels, and nerves of each lung (Figure 10-51). The two layers of the pleura (the *visceral* layer and the *parietal* layer) are so close they are virtually in contact with each other. The pleurae are separated by a thin fluid that acts as a lubricant. This fluid allows the pleural membranes to slide past each other during respiration.

Between the two pleurae is a potential space known as the **pleural space**. When significant chest wall injury or pathologic pulmonary condition occurs, the pleural space may become filled with air *(pneumothorax)* or blood *(hemothorax)*. Another fluid that may accumulate in the pleural space is *transudates*. Transudates most commonly accumulate because of congestive heart failure. Another type of fluid collection is *exudates*. Exudates can result from infectious or malignant conditions.

Digestive System

The digestive system provides the body with water, **electrolytes**, and other nutrients used by cells. To accomplish this task, the digestive system is specialized to ingest food. It then propels the food through the gastrointestinal tract (digestive tract). Lastly, the digestive system absorbs nutrients across the wall of the lumen of the gastrointestinal tract.

The gastrointestinal tract is an irregularly shaped tube. Associated accessory organs (mainly glands) secrete fluid into the digestive tract. The first part of the digestive tract is the oral cavity. The *salivary glands* and tonsils are accessory organs of the oral cavity. The oral cavity opens posteriorly into the pharynx. The pharynx opens inferiorly into the esophagus. The esophagus opens inferiorly into the stomach (through the muscular **cardiac sphincter**). In the stomach small glands secrete acids and enzymes that help with digestion. The cardiac sphincter stops food from reentering the esophagus when the stomach contracts.

The stomach opens into the **duodenum**, the first section of the small intestine. Important accessory structures in this segment of the gastrointestinal tract are the **liver**, the **gallbladder**, and the **pancreas**. The **jejunum**, the major site of absorption, is the next segment of the **small intestine**. The last segment of the small intestine is the ileum. The **ileum** is similar in function to the jejunum but has fewer digestive enzymes and provides less absorption.

The last section of the digestive tract is the **large intestine;** its functions are to absorb water and salts and to concentrate undigested food into feces. The major accessory glands secrete mucus. The first segment of the large intestine is the **cecum** with its attached appendix. The cecum is followed by the *ascending, transverse, descending,* and *sigmoid* portions of the colon and the rectum. The **rectum** joins the anal canal, which ends at the **anus**.

FUNCTIONS OF THE DIGESTIVE TRACT

As food moves through the digestive system, secretions are added to liquefy and digest it. These secretions also provide lubrication. The processes of *secretion*, *movement*,

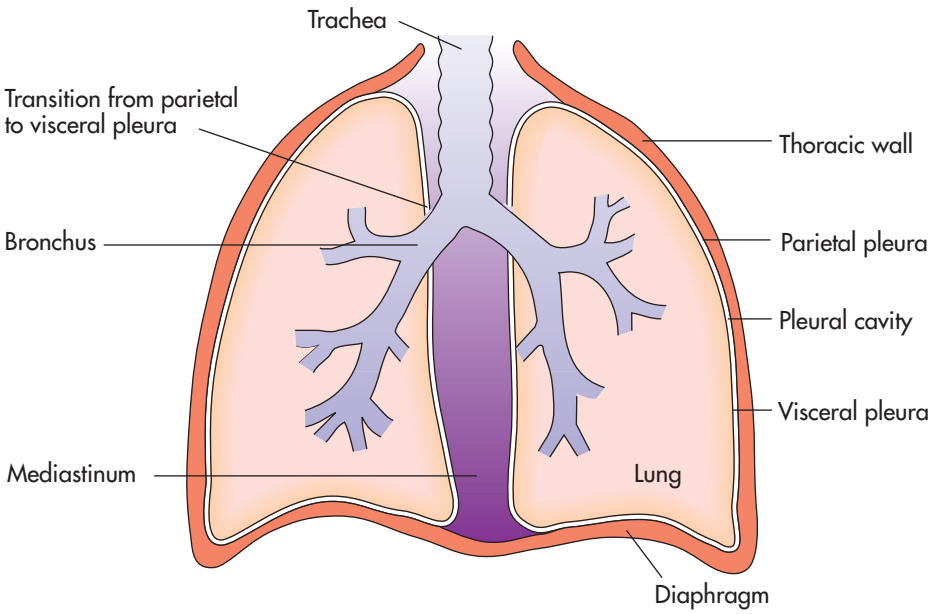

FIGURE 10-51 Lungs surrounded by the pleural cavities.

and *absorption* are regulated by nervous and hormonal mechanisms.

ORAL CAVITY

Saliva contains a digestive enzyme referred to as *salivary amylase*. This enzyme begins the chemical digestion of carbohydrates. In addition, saliva prevents bacterial infection in the mouth. It does this by washing the oral cavity with certain substances. These substances offer a weak antibacterial action. Salivary gland secretion is stimulated by the parasympathetic and sympathetic nervous systems. The parasympathetic nervous system controls salivation in the relaxed state.

The teeth chew food in the mouth to break it up, which aids swallowing and processing. Food then is swallowed by voluntary and involuntary actions. The pharynx elevates to receive the food from the mouth. As the pharyngeal muscles contract, the upper esophageal sphincter relaxes, the esophagus opens, and the food is pushed into the esophagus. During this phase of swallowing, the vocal folds are moved medially. The epiglottis is tipped posteriorly to close the entrance of the airway and prevent aspiration.

Muscular contractions in the esophagus occur in *peristaltic waves*. These waves push the food through the esophagus toward the stomach. The contractions cause the cardiac sphincter (also known as the *lower esophageal sphincter*) to relax, and they then push the food into the stomach.

STOMACH

The stomach acts primarily as a storage area and mixing chamber for ingested food. Although some digestion and absorption occur in the stomach, these are not its major functions. The stomach secretes mucus to protect the surface of the stomach wall and duodenum. The stomach is lined by mucous membranes that contain thousands of microscopic gastric glands. These gastric glands secrete *hydrochloric acid, intrinsic factor,* gastrin, and *pepsinogen*.

The stomach produces about 2 to 3 L of gastric secretions each day. Secretion is regulated by nervous and hormonal mechanisms. The ingested food is mixed well with the secretions of the stomach glands to produce a semisolid mixture called **chyme**. Movements resembling peristalsis slowly force chyme toward the *pyloric sphincter,* through the *pyloric opening,* and into the duodenum (Figures 10-52 and 10-53).

NOTE
A liter is equal to 1.06 quarts. One gallon is equal to 3.79 L.

SMALL INTESTINE

The mucosa of the small intestine produces secretions that contain mucus, electrolytes, and water. These substances lubricate the intestinal wall. They also protect the intestine from the acidic chyme and digestive enzymes. In addition, secretions of the liver and pancreas enter the small intestine to aid the digestive process.

The main functions of the small intestine are the mixing and propulsion of chyme and the absorption of fluid and nutrients. Peristaltic contractions move the chyme through the small intestine toward the *ileocecal sphincter*. At this point, the chyme enters the cecum. When the chyme causes the cecum to distend, the sphincter closes. This closure

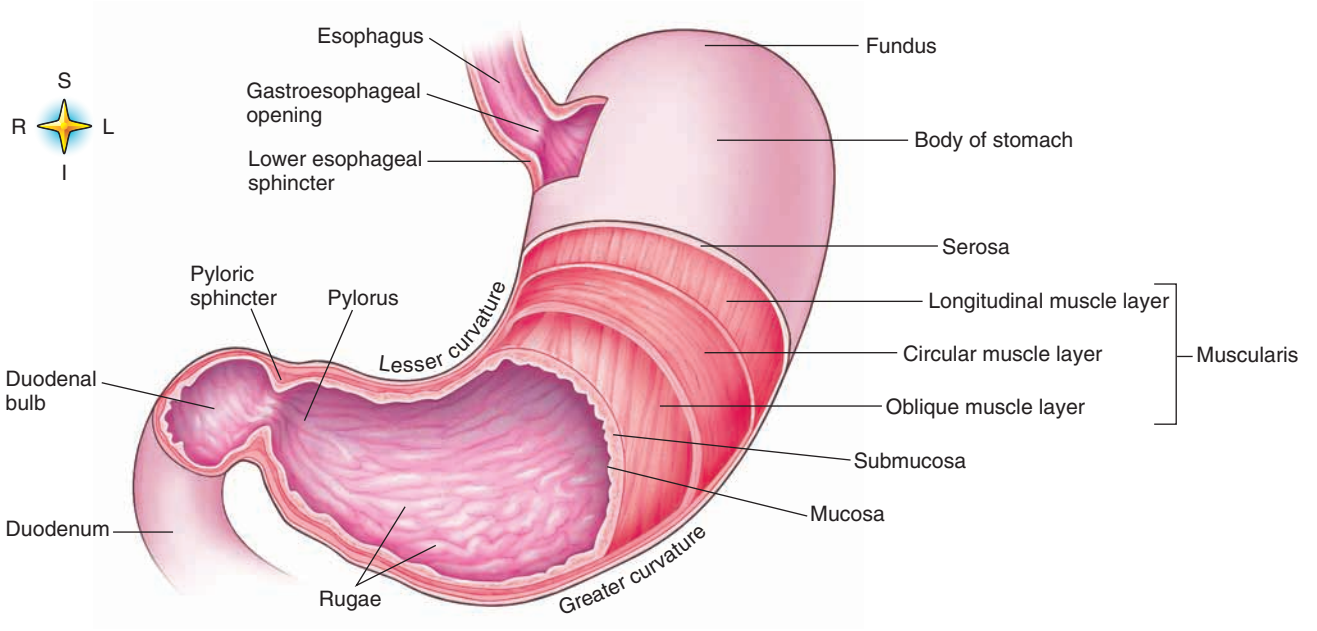

FIGURE 10-52 Muscle layers of the stomach wall. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

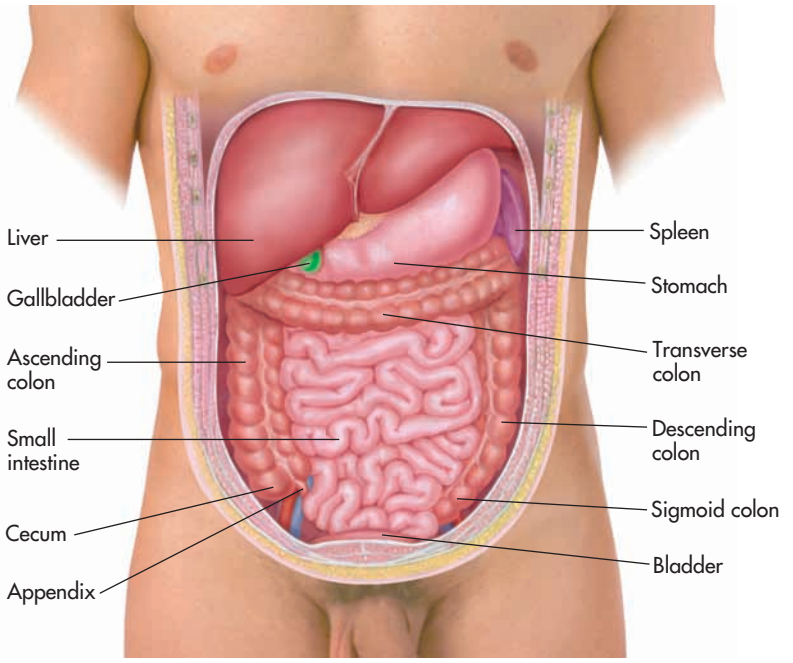

FIGURE 10-53 Digestive organs. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

slows the rate of movement of chyme from the small intestine into the large intestine. Closure also prevents material from returning to the ileum from the cecum.

CRITICAL THINKING
What might happen if the excretion of protective mucus in the small bowel is impaired?

LIVER

The liver is the largest internal organ. It serves a number of biochemical functions. It lies just under the diaphragm in the upper regions of the abdominal cavity. The liver is a vascular organ that gets a blood supply from two sources, the **hepatic artery** and the **portal vein**. The liver plays a major role in iron metabolism, plasma protein production, detoxification of drugs and other substances circulating in plasma, and many other biochemical pathways.

NOTE
A milliliter is equal to 0.5 teaspoon volume. One tablespoon volume is equal to 15 mL.

The liver secretes about 600 to 1000 mL of **bile** each day. Bile contains no digestive enzymes, but it dilutes stomach acid and emulsifies fats. Most bile salts are reabsorbed in the ileum and are carried back to the liver in the blood. Other bile salts are lost through feces.

In addition to secreting bile, the liver has other functions that are needed for healthy survival. The liver plays a major role in the metabolism of certain foods. It also helps maintain a normal blood glucose concentration. The liver is a line of defense against many byproducts of metabolism that are toxic if they collect in the body. Blood proteins (e.g., *albumin, fibrinogen, globulins,* and *clotting factors*) also are made and released into the circulation by the liver.

GALLBLADDER

Bile is secreted regularly by the liver and is stored in the gallbladder. When chyme containing lipid or fat enters the duodenum, the gallbladder is stimulated by the hormones *cholecystokinin* and *secretin*. These hormones are secreted by the intestinal mucosa. The stimulation causes the gallbladder to contract, forcing concentrated bile into the small intestine. The only role of the gallbladder is to concentrate and store the bile made by the liver.

CRITICAL THINKING
When is the person who suffers from gallstones (cholelithiasis) most likely to have pain? Why?

PANCREAS

The pancreas is an **exocrine gland**. It secretes *pancreatic juice*. In addition, the pancreas is an endocrine gland that secretes hormones (e.g., insulin) into the blood. Pancreatic juice is the most critical digestive juice. The juice consists of digestive enzymes, sodium bicarbonate, and alkaline substances that neutralize the hydrochloric acid in the chyme entering the small intestine. Pancreatic juice also holds *amylase*. The amylase continues the digestion that began in the oral cavity.

LARGE INTESTINE

Chyme moves through the small intestine in 3 to 5 hours. Passage through the large intestine, however, takes 18 to 24 hours. Processes involving the absorption of water and salts, the secretion of mucus, the action of microorganisms, and the conversion of chyme produce feces. Feces remain in the colon until eliminated through defecation.

The contents of the large intestine are forced toward the anus by peristaltic contractions. These contractions occur three or four times a day. During the movement of chyme through the large intestine, bacteria act on material that escaped digestion in the small intestine. As a result of this action, more nutrients may be released and absorbed. Some of the bacteria also synthesize vitamin K. This vitamin is needed for normal blood clotting to produce the vitamin B complex. Once formed, these vitamins are absorbed from the large intestine and enter the blood.

Distention of the rectal wall by feces starts the defecation reflex. This reflex causes weak contractions and relaxations of the *internal anal sphincter*. The *external anal sphincter* (under conscious cerebral control) stops the passage of feces out of the rectum until it is relaxed. During defecation, pressure in the abdominal cavity increases. This pressure forces the contents of the colon through the anal canal and out the anus.

Urinary System

The urinary system works with other body systems to maintain homeostasis. It does this by removing waste products from the blood and by helping to maintain a constant body fluid volume and composition. The kidneys also are involved in the control of red blood cell production and metabolism of vitamin D. The urinary system is made up of two kidneys, two ureters, the urinary bladder, and the urethra.

CRITICAL THINKING

Think about patients with renal failure. Why should you anticipate anemia and decreased calcium levels?

KIDNEYS

Each **kidney** is shaped much like a kidney bean. The two kidneys lie on the posterior abdominal wall behind the peritoneum. They are on either side of the vertebral column near the lateral border of the *psoas muscles*. The superior pole of each kidney is protected by the rib cage. The right kidney is slightly lower than the left because of the superior position of the liver. A fibrous *renal capsule* surrounds each kidney, as does a dense deposit of adipose tissue that protects the kidney from injury.

The kidney is divided into an *outer cortex* and an *inner medulla*. The medulla consists of a number of triangular divisions. These divisions are called the **renal pyramids**. They extend into the cortex (Figure 10-54). The *papilla* is the innermost end of a pyramid. Several large urinary tubes *(calyces)* extend to the renal pelvis from the kidney tissue.

The basic functional unit of the kidney is the **nephron**. The nephron is made up of a large terminal end (called a *renal corpuscle*), a proximal convoluted tubule, the **loop of Henle**, and a distal convoluted tubule. The distal convoluted tubule empties into a collecting duct. This duct carries the urine from the cortex of the kidney to the calyces. The terminal end of the nephron is enlarged to form **Bowman's capsule**. The wall of Bowman's capsule is indented to form a double-walled chamber occupied by a network of blood capillaries known as the **glomerulus**. Together, the glomerulus and Bowman's capsule form the renal corpuscle.

URETERS, URINARY BLADDER, AND URETHRA

The **ureters** extend from the renal pelvis to the urinary bladder. The triangular area of the bladder wall between the two ureters and the urethra is called the *trigone*. (Figure 10-55 depicts the male urinary bladder.) This region differs from the rest of the bladder wall in that it does not expand during bladder filling.

The **urinary bladder** is a hollow, muscular organ. It lies in the pelvic cavity just posterior to the pubic symphysis. The size of the bladder depends on the volume of urine.

CRITICAL THINKING

Why is the bladder more susceptible to injury when full than when empty?

At the junction of the urethra and the urinary bladder, smooth muscle of the bladder forms the *internal urinary sphincter*. The external urinary sphincter surrounds the urethra as the urethra extends through the pelvic floor. These sphincters control the flow of urine through the urethra. In the male, the urethra extends to the end of the penis, where it opens to the outside. The female urethra is much shorter than the male urethra. It opens into the vestibule anterior to the vaginal opening.

URINE PRODUCTION

Nephrons are the structural parts of the kidney and are the location where urine is produced. The more than 2 million nephrons form urine in a three-step process of filtration, reabsorption, and secretion.

1. The first step of urine formation is the passage of fluid from the glomerular capillaries. This fluid passes into Bowman's capsule. Blood flowing through the glomeruli exerts pressure. This pressure pushes water and small dissolved molecular substances out of the glomeruli and into the Bowman's capsule. Simply stated, glomerular blood pressure causes filtration through the glomerular capillaries. Glomerular filtration normally occurs at the rate of 125 mL/min or 180 L/day (glomerular filtration rate). Ninety percent of this filtrate is reabsorbed. Healthy individuals produce 1 to 2 L of urine a day.

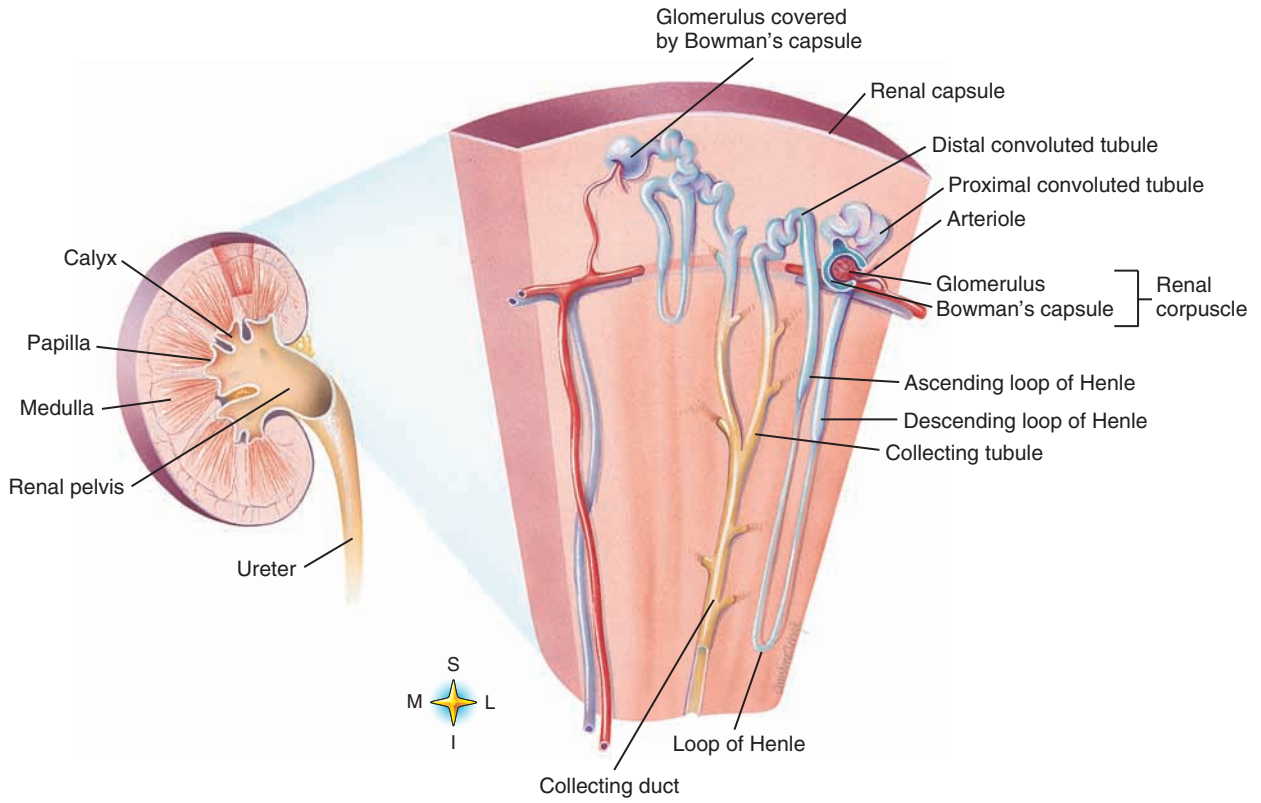

FIGURE 10-54 Magnified wedge cut from a renal pyramid. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

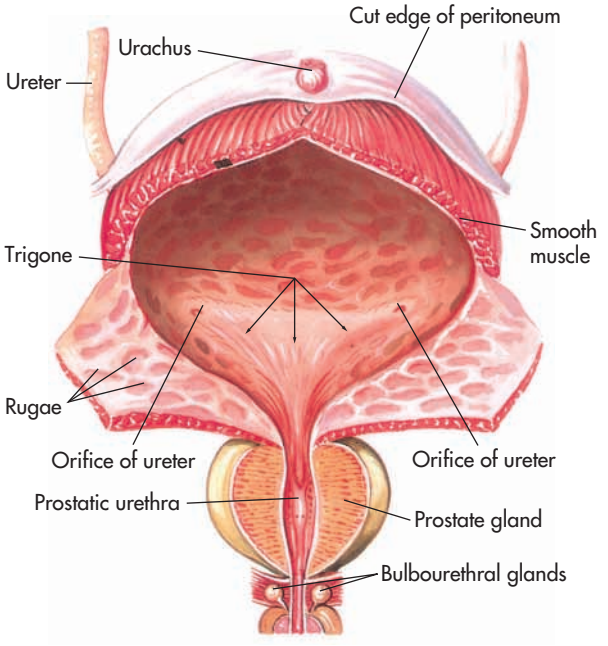

FIGURE 10-55 Male urinary bladder. (Christensen BL, Kockrow EO: *Adult health nursing,* ed 6, St Louis, 2010, Mosby.)

2. Upon leaving the renal capsule, the filtrate flows through the proximal convoluted tubule, the loop of Henle, the distal convoluted tubule, and into the collecting duct. During this process, many substances in the filtrate are reabsorbed by the blood capillaries around the tubules. These substances reenter the general circulation. Substances that are reabsorbed include water, glucose and other nutrients, and most of the sodium and other **ions**.
3. Secretion is the process by which substances move into urine in the distal convoluted tubule and collecting duct from blood in the capillaries around these structures. Reabsorption moves substances out of the urine and into the blood. Secretion, however, moves substances out of the blood and into the urine. Secreted substances include hydrogen and potassium ions, ammonia, and certain drugs. (Figure 10-56 depicts the formation of urine.)

URINE REGULATION

The body usually can control the amount and makeup of the urine it secretes. This involves hormonal mechanisms, autoregulation, and sympathetic nervous system stimulation.

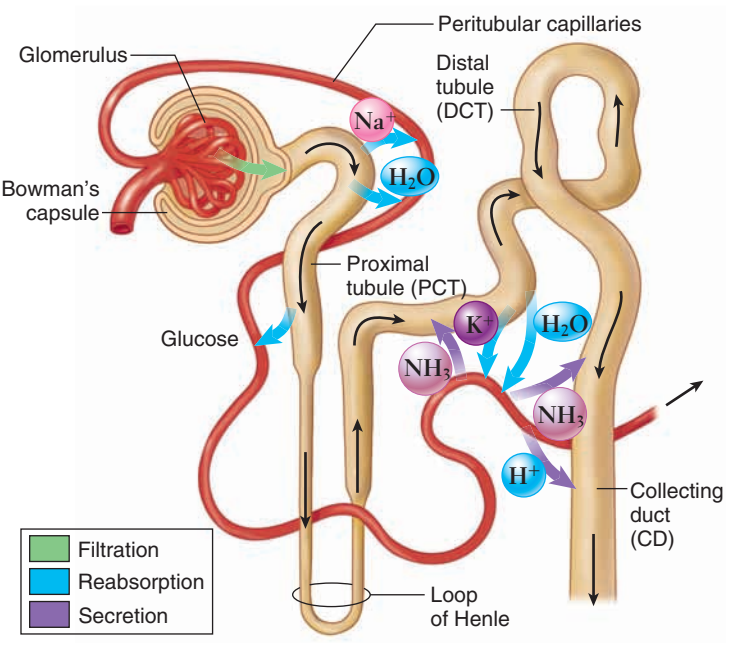

FIGURE 10-56 Formation of urine. The steps in urine formation in successive parts of a nephron are filtration, reabsorption, and secretion. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

Aldosterone is a steroid hormone secreted by the adrenal gland. It passes through the circulatory system from the adrenal gland to the kidney. Aldosterone stimulates the tubules to reabsorb sodium salts and water.

Antidiuretic hormone (ADH), which is secreted by the posterior pituitary gland, tends to reduce the amount of urine produced by making distal and collecting tubules permeable to water, thus increasing water reabsorption. As a result, water is retained by the body in the presence of ADH.

Atrial natriuretic factor (ANF) is a hormone secreted from the cells in the right atrium of the heart when the pressure in the right atrium increases. This hormone inhibits ADH secretion. It also reduces the kidneys' ability to concentrate urine. As a result, the body produces a large volume of dilute urine.

Prostaglandins and *kinins* are substances formed in the kidneys that affect kidney function. These substances are believed to influence the rate of filtrate formation and sodium ion reabsorption.

Autoregulation is the ability of the kidneys to regulate a stable glomerular filtration rate over a wide range of systemic blood pressures. When small increases in glomerular capillary pressure occur, the rate of filtrate formation increases substantially. Therefore, large increases in the arterial blood pressure increase the rate of urine production. Conversely, when the arterial blood pressure decreases, urine production decreases. Through autoregulation the kidneys change the degree of constriction or dilation of the arterioles in the renal capsule to maintain glomerular capillary pressure and urine production within normal limits over a wide range of arterial blood pressures.

Sympathetic neurons innervate the blood vessels of the kidney. The sympathetic stimulation in response to severe stress, intense exercise, or circulatory shock constricts the small arteries and the afferent arterioles. This reduces renal blood flow.

Reproductive System

Most organs and systems of the human body are the same in the male and female. However, the reproductive systems are different. The purpose of the male reproductive system is to make **spermatozoa** and to transfer the spermatozoa to the female. The purpose of the female reproductive system is to make **oocytes**. Other purposes include receiving the spermatozoa to enable fertilization, conception, gestation, and birth.

MALE REPRODUCTIVE SYSTEM

The male reproductive system consists of the testes, epididymis, ductus deferens, urethra, seminal vesicles, prostate gland, bulbourethral glands, scrotum, and penis (Figure 10-57).

The **testes** are ovoid organs in the scrotum that develop as retroperitoneal organs in the abdominopelvic cavity. The testes move from the abdominal cavity to the scrotum by way of the **inguinal canal**. This canal is common to men and women. Normally the inguinal canal is closed, but it persists as a weak spot in the abdominal wall where the testes pass through it. If the inguinal canal weakens or ruptures, an *inguinal hernia* may result.

Interstitial cells of the testes secrete the male hormone *testosterone*. Before **puberty** (12 to 14 years of age), the testes remain relatively simple and unchanged. At the time of puberty, however, the interstitial cells increase in number and size. At this time, the production of spermatozoa begins. The testes contribute about 5% of the seminal fluid **(semen)**.

The final maturation of spermatozoa occurs in the **epididymis**. This is a convoluted, comma-shaped structure on the posterior side of the testis. Infection or injury can block a single epididymis or both of them. This in turn can result in infertility.

The **ductus deferens** (also called the *vas deferens*) emerges from the tail of the epididymis. This duct ascends to the *seminal vesicle,* finally associating with the blood vessels and nerves that supply the testis. These structures and their coverings constitute the *spermatic cord*. The ductus deferens and the spermatic cord structures ascend and pass through the inguinal canal to enter the abdominal cavity. The ductus deferens crosses the lateral wall of the cavity. The duct then travels over the ureter and loops over the posterior surface of the urinary bladder to approach the prostate gland. The ductus deferens is surrounded by smooth muscle. This muscle helps propel sperm through the duct.

The **urethra** is a passageway for urine and male reproductive fluids. It can be divided into three parts: the *prostatic*

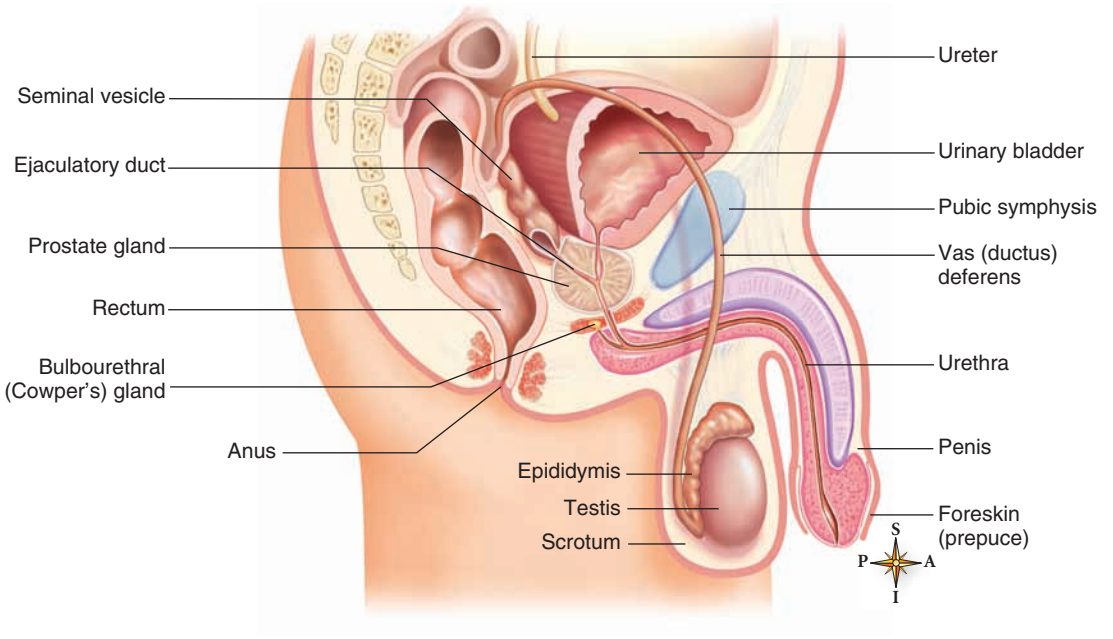

FIGURE 10-57 Sagittal section of the male pelvis. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

portion (the portion that passes through the prostate gland); the *membranous portion* (which extends from the prostatic urethra through the muscular floor of the pelvis); and the *spongy portion* (which extends the length of the penis).

The **seminal vesicle** is a sac-shaped gland that lies adjacent to each ductus deferens. A short duct from the seminal vesicle joins the ductus deferens to form the *ejaculatory duct*. These ducts project into the prostate gland and end by opening into the urethra. Seminal vesicles produce about 60% of seminal fluid.

The **prostate gland** consists of glandular and muscular tissue. It is about the size and shape of a walnut. The gland is located dorsal to the symphysis pubis at the base of the bladder and surrounds the prostatic urethra and the two ejaculatory ducts. Twenty to 30 small *prostatic ducts* secrete prostatic fluid into the prostatic urethra. The prostate gland contributes about 30% of seminal fluid.

The **bulbourethral glands** are a pair of small glands located near the membranous portion of the urethra. In young adults these glands are each about the size of a pea, but they decrease in size with age. The gland is a compound mucous gland with small ducts that unite to form a single duct from each gland. The two bulbourethral glands enter the spongy urethra at the base of the penis. They add secretions to semen, contributing about 5% of seminal fluid.

The **scrotum** is divided into two internal compartments by a connective tissue septum. Beneath the skin of the scrotum is a layer of *superficial fascia* (loose connective tissue) and a layer of cutaneous muscle. This muscle is called the *dartos muscle*. The *dartos* and *cremaster muscles* of the abdomen are crucial for regulating temperature in the testes (which is required for **spermatogenesis**). They pull the testes near the body in cold temperatures. They also allow the testes to descend away from the body in warm temperatures and during exercise.

CRITICAL THINKING

If a patient's prostate gland is greatly enlarged by benign or malignant disease, what symptoms would you expect?

The **penis** consists of three columns of erectile tissue. Engorgement of this tissue with blood causes the penis to enlarge and become firm, producing an **erection**. The penis is the male organ of copulation and functions in the transfer of spermatozoa from the male to the female.

FEMALE REPRODUCTIVE SYSTEM

The female reproductive organs consist of the ovaries, uterine (or fallopian) tubes, uterus, vagina, external genital organs, and mammary glands. The internal reproductive organs lie within the pelvis between the urinary bladder and the rectum. These organs are held in place by a group of ligaments (Figure 10-58).

The small **ovaries** are attached to the posterior of the broad ligament called the *mesovarium*. Two other ligaments associated with the ovary are the *suspensory ligament* and the *ovarian ligament*. The ovarian arteries, veins, and nerves traverse the suspensory ligament. They enter the ovary through the mesovarium. Each ovary has a dense outer portion called the *cortex*. Each ovary also has a looser inner portion called the *medulla*. Many small vesicles, called **ovarian follicles** (each of which contains an oocyte), are distributed throughout the cortex.

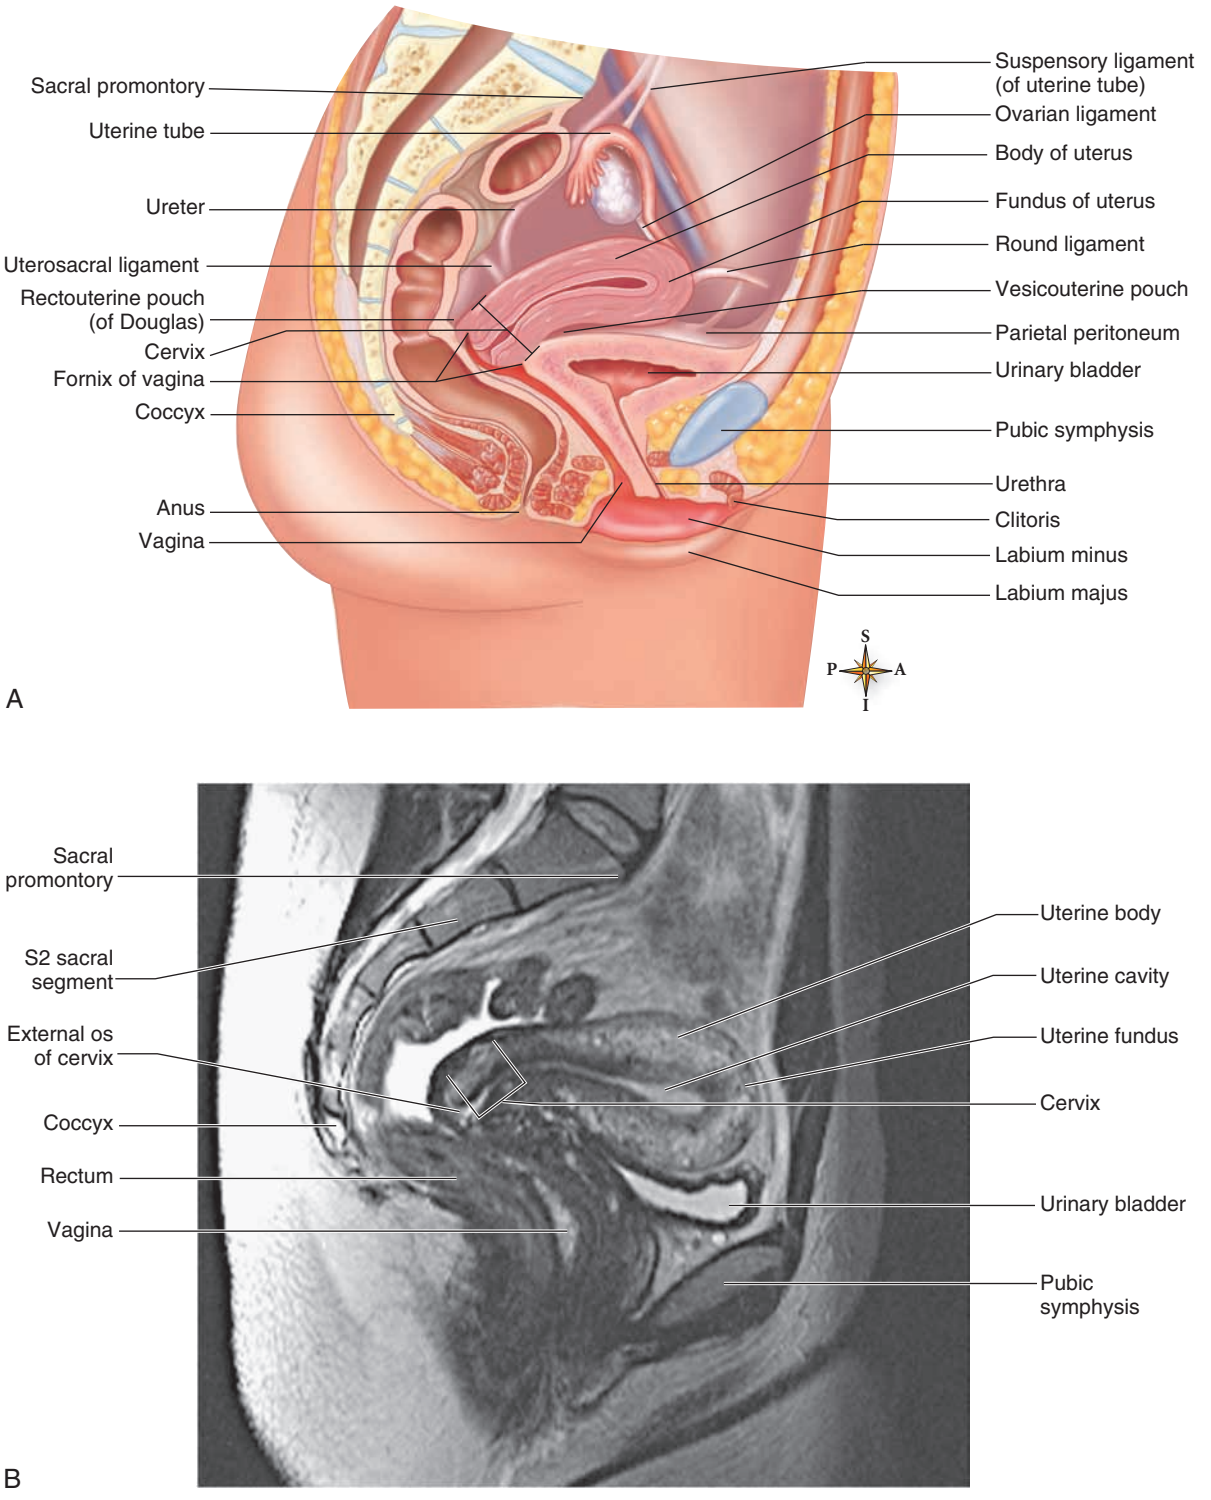

FIGURE 10-58 Sagittal section of the female pelvis. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

The **uterine tubes** are ducts for the ovaries. Each tube is located along the superior margin of the broad ligament. Each one opens right into the peritoneal cavity to receive the oocyte. Once inside the uterine tube, the oocyte is transported by cilia and peristaltic contractions of the smooth muscle in the uterine tube.

The **uterus** is the size and shape of a medium-sized pear. It is oriented in the pelvic cavity with the larger rounded portion (the *fundus*) directed superiorly. The narrower portion, the **cervix**, is directed inferiorly. The main portion of the uterus (the *body*) is positioned between the fundus and the cervix. The major ligaments that hold the uterus in

place are the *broad ligament, round ligaments,* and *uterosacral ligaments* (Figure 10-59).

The **vagina** is the female organ of copulation. It functions to receive the penis during intercourse. The vagina extends from the uterus to the outside of the body. It provides a passageway for menstrual flow and for childbirth. The smooth muscle layer of the vagina allows the organ to increase in size to accommodate the penis during intercourse and to stretch greatly during delivery. The vaginal orifice is covered by a thin mucous membrane called the **hymen**. The openings in the hymen usually are enlarged during the first sexual intercourse but also may be perforated or torn during strenuous exercise.

The external genitalia is referred to as the **vulva**. The vulva consists of the vestibule and its surrounding structures (Figure 10-60). The vestibule is the space into which the vagina and urethra open. It is bordered by a pair of thin, longitudinal skin folds called the *labia minora*. A small erectile structure, called the **clitoris**, is located in the anterior margin of the vestibule. The two labia minora unite over

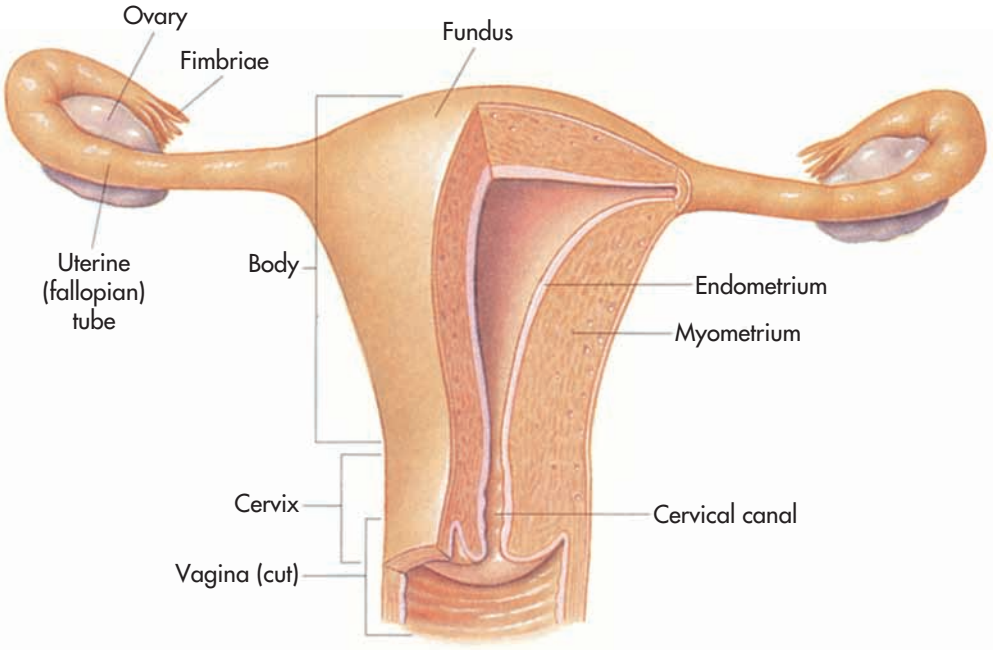

FIGURE 10-59 Internal anatomy of the female pelvis. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

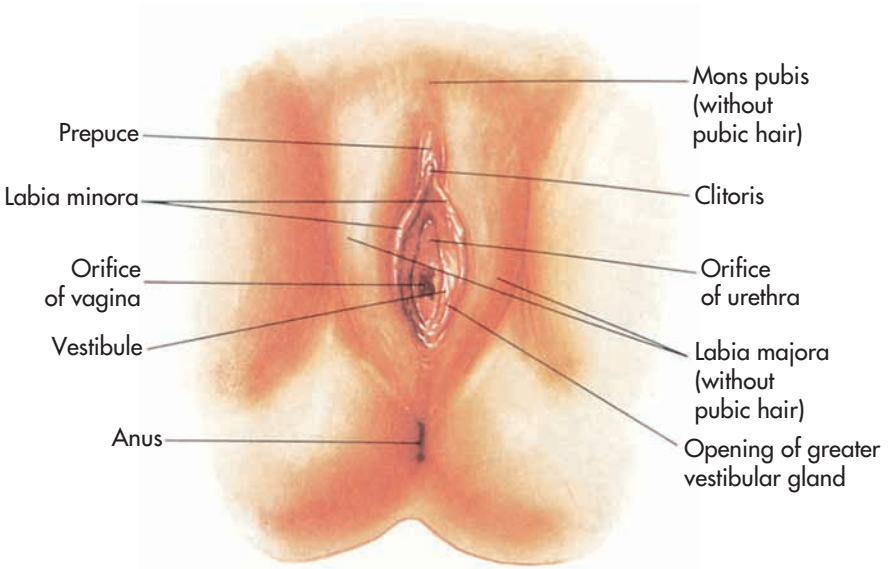

FIGURE 10-60 Female external genitalia. (Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

the clitoris to form a fold of skin known as the *prepuce*. Lateral to the labia minora are two prominent folds of skin called the *labia majora*. These folds unite anteriorly in an elevation over the pubic symphysis to form the **mons pubis**. Most of the time, the labia majora are in contact with each other. They conceal the deeper structures within the vestibule.

The **perineum** is divided into triangles by perineal muscles. The *urogenital triangle* contains the external genitalia. The posterior anal triangle contains the anal opening. The region between the vagina and the anus is called the *clinical perineum*. This area sometimes tears during childbirth.

The **mammary glands** are the organs of milk production. They are located in the breasts, or *mammae*. Externally, the breasts of males and females have a raised nipple surrounded by a circular pigmented **areola**. Nipples are sensitive to tactile stimulation. They may become erect in response to sexual arousal. The areolae normally have a slightly bumpy surface due to the presence of areolar glands just below their surface. Secretions from these glands protect the nipple and areola from chafing during nursing.

Female breasts begin to enlarge during puberty (usually between ages 12 and 13) under the effect of *estrogen* and *progesterone*. Each adult female mammary gland is made up of 15 to 20 glandular lobes covered by adipose tissue. Each lobe has a single *lactiferous duct*. This duct subdivides to form smaller ducts, each of which supplies a lobule. These ducts expand at their ends to form secretory sacs called *alveoli*. The alveoli secrete milk during nursing (Figure 10-61).

SPECIAL SENSES

Senses provide the brain with information about the outside world. Four senses are recognized as special senses: (1) *smell,* (2) *taste,* (3) *sight,* and (4) *hearing* and *balance*. (The sense of touch now is considered a general sense, which consists of several types of nerve endings scattered throughout the body and not localized to a specific area.)

Olfactory Sense Organs

The smell receptors for the fibers of the **olfactory** (first cranial) nerve lie in the mucosa of the upper part of the nasal cavity (Figure 10-62). Most of the nasal cavity is involved with respiration. Only a small part is devoted to smell.

The dendrites of olfactory neurons extend to the epithelial surface of the nasal cavity, where they form vesicles. These vesicles have long **cilia**. The cilia lie in a thin, mucous film on the epithelial surface. Olfactory cells are stimulated by molecules in the air. The resulting nerve impulses travel through the olfactory nerves in the *olfactory bulb* and *olfactory tract*. In the olfactory tract the impulses enter the thalamic and olfactory centers of the brain. In the brain the nervous impulses are interpreted as specific odors.

The exact mechanism of olfactory stimulation is not understood clearly. The range of smells is thought to be actually just a combination of seven main odors: (1) camphoraceous, (2) musky, (3) floral, (4) peppermint, (5) ethereal, (6) pungent, and (7) putrid. Olfactory receptors are sensitive, even to slight odors. However, they also are fatigued easily. The olfactory system quickly adapts to

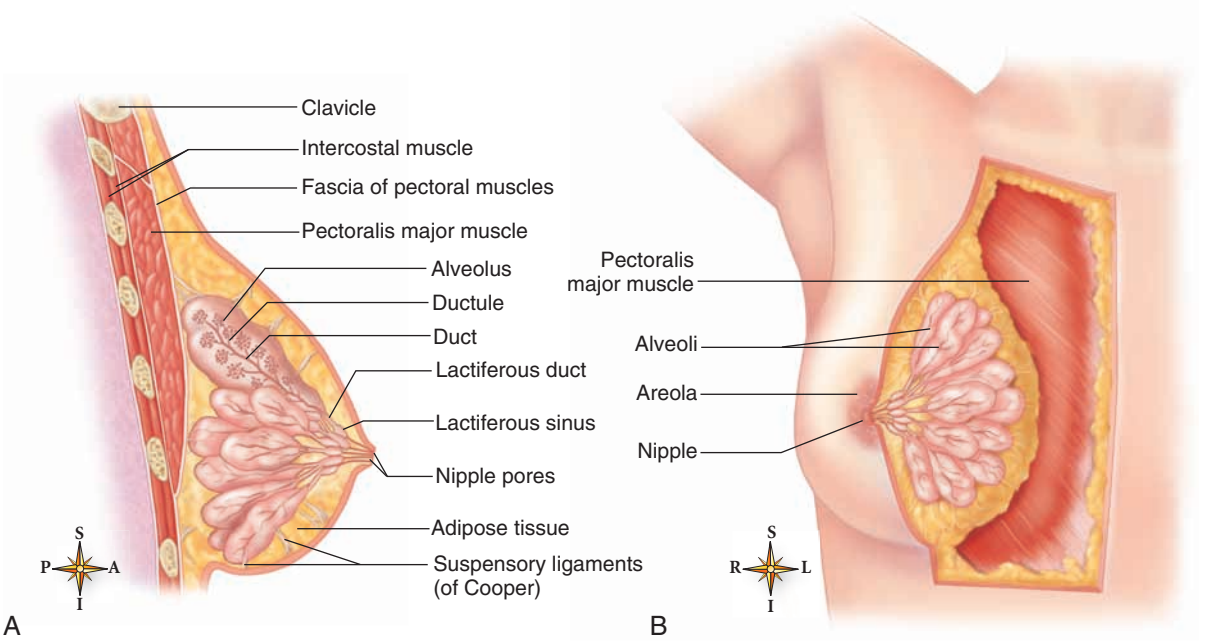

FIGURE 10-61 Blood supply, mammary glands, and duct system of the right mamma. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

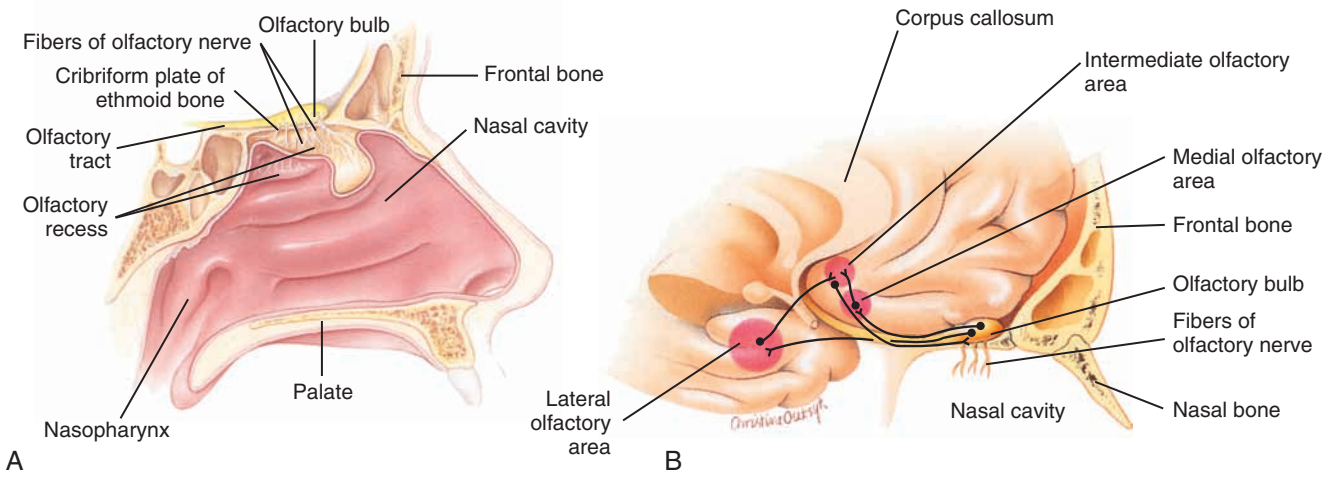

FIGURE 10-62 Olfactory structures. Gas molecules stimulate olfactory cells in the nasal epithelium. Sensory information is conducted along nerves in the olfactory bulb and olfactory tract to sensory processing centers in the brain. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

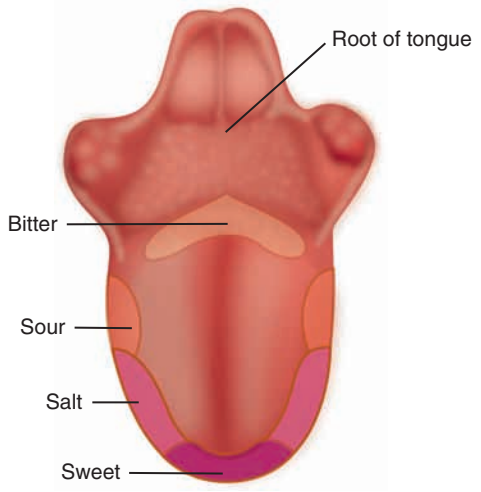

FIGURE 10-63 Tongue. Dorsal surface and regions sensitive to various tastes.

ongoing stimulation. In fact, a certain odor may cease to be noticed in a short time. This is a key factor to consider when dealing with hazardous materials incidents (see Chapter 57).

Taste

The sensory structures that detect taste stimuli are called the **taste buds**, and the receptors for the taste nerve fibers are in the seventh and ninth cranial nerves. Most taste buds are associated with specialized portions of the tongue. However, taste buds also are located on other areas of the tongue, palate, lips, and throat.

Taste detected by taste buds can be divided into four basic types: bitter, sour, salty, and sweet. The tip of the tongue reacts more strongly to sweet and salty tastes, the back of the tongue to bitter taste, and the sides of the tongue to sour taste (Figure 10-63). All the other taste sensations result from a combination of taste bud and olfactory receptor stimulation.

Visual System

The visual system includes the *eyes*, the *accessory structures* (eyelids, eyebrows, eyelashes, and tear glands), and the *optic nerve, tracts,* and *pathways*. The second cranial nerve **(optic nerve)** conducts impulses from the eye to the brain. In the brain these impulses create the sensation of vision. The third cranial nerve **(oculomotor nerve)** conducts impulses from the brain to the muscles of the eye, where they cause contractions that move the eye.

CRITICAL THINKING

Why is an examination of the eyes a key part of the neurological evaluation?

ANATOMY OF THE EYE

The eye is composed of three layers: the fibrous tunic, consisting of the sclera and cornea; the vascular tunic, consisting of the choroid, ciliary body, and iris; and the nervous tunic, consisting of the retina (Figure 10-64).

1. The **sclera** is the firm, opaque, white outer layer of the eye. It helps to maintain the shape of the eye, protects the internal structures of the eye, and provides an attachment point for the muscles that move the eye. The sclera is continuous with the meningeal layers of the brain that extend along the optic nerve. The **cornea** is continuous with the sclera. The cornea is an avascular, transparent structure that permits light to enter the eye. It also bends and refracts entering light.
2. The **vascular tunic** contains most of the blood vessels of the eyeball. The part of this layer associated with the sclera is the *choroid*. Anteriorly, the vascular tunic

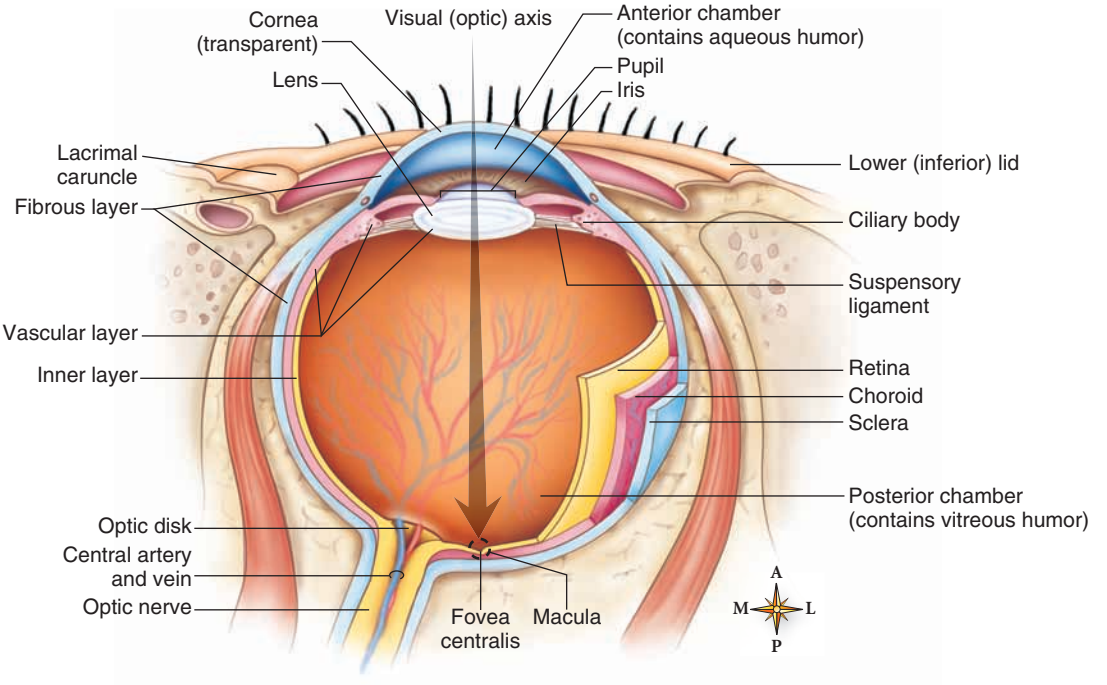

FIGURE 10-64 Horizontal section through the left eyeball. The eye is viewed from above. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

consists of the *ciliary body* and the *iris*. The ciliary body consists of ciliary muscles (which can change the shape of the lens) and of complex capillaries involved in producing **aqueous humor**. The **iris** is the colored part of the eye. It consists mainly of smooth muscle that surrounds the **pupil**. Light enters through the pupil, and the iris regulates the amount of light by controlling the size of the pupil.

3. The **retina** consists of an outer pigmented retina and an inner sensory layer, which responds to light. The sensory retina contains photoreceptor cells, called *rods* and *cones,* and numerous relay neurons. Rods are the receptors for night vision. Cones are the receptors for daytime and color vision.

COMPARTMENTS OF THE EYE

The two compartments of the eye are separated by a **lens**. The lens is suspended between the two eye compartments by ligaments. These two compartments are known as the *anterior* and *posterior chambers*. The anterior chamber is filled with *aqueous humor.* This helps maintain **intraocular pressure** (pressure within the eye that keeps the eye expanded), refract light, and provide nutrition for the anterior chamber.

The posterior chamber of the eye is surrounded almost completely by the retina. The chamber is filled with a transparent, jelly-like substance called **vitreous humor**. Like aqueous humor, the vitreous humor helps maintain intraocular pressure. In addition, the fluid helps to hold the retina in place and functions in the refraction of light in the eye.

ACCESSORY STRUCTURES OF THE EYE

The accessory structures of the eye protect, lubricate, move, and aid in the function of the eye. These structures include the eyebrows, eyelids, conjunctivae, and lacrimal gland.

Eyebrows protect the eyes by providing shade from direct sunlight. They also prevent perspiration from running into the eyes.

Eyelids protect the eyes from foreign objects. Blinking, which normally occurs about 25 times per minute, helps lubricate the eyes by spreading tears over their surfaces. Eyelids also help regulate the amount of light entering the eyes.

The **conjunctiva** is a thin, transparent mucous membrane. It covers the inner surface of the eyelids and the outer surface of the sclera.

The **lacrimal gland** makes lacrimal fluid (tears) that leaves the gland through several ducts, passing over the anterior surface of the eyeball. The gland is in the superolateral corner of the orbit. The gland makes tears to moisten the surface of the eye, lubricate the eyelids, and wash away foreign objects. Tears also contain lysosomes that destroy some forms of bacteria.

Most tears evaporate from the surface of the eye. Excess fluid is collected in the medial corner of the eye by the lacrimal canals through a *punctum* (the opening of each canal). The lacrimal canals open into a *lacrimal sac*. This sac in turn continues into the *nasolacrimal duct* (Figure 10-65).

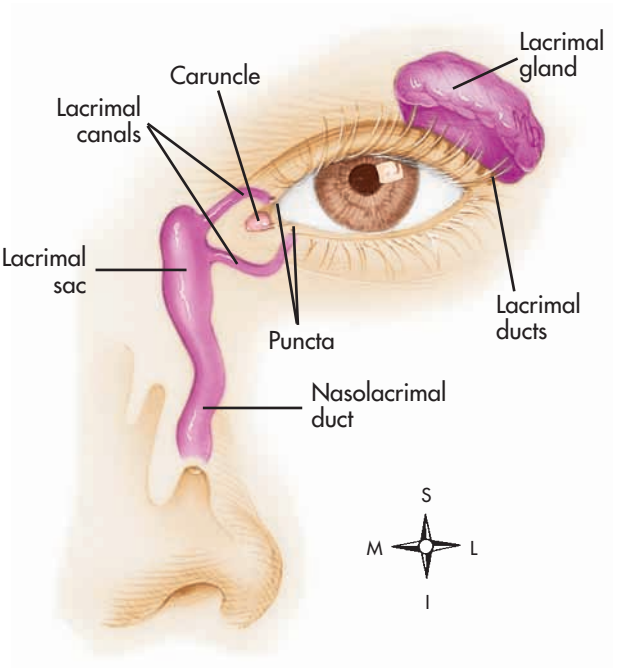

FIGURE 10-65 Lacrimal structures of the eye. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis 2005, Mosby.)

Hearing and Balance

The organs of hearing can be divided into three portions: the external ear, the middle ear, and the inner ear (Figure 10-66). The external ear and middle ear are involved only in hearing. The inner ear, however, functions in hearing and balance. The special senses of hearing and balance are transmitted by the *vestibulocochlear nerve* (eighth cranial nerve).

The **external ear** includes the *auricle,* or *pinna*. It also includes the *external auditory meatus,* which opens into the *external auditory canal*. The external auditory canal is lined by hairs and ceruminous glands. These glands make cerumen. This canal terminates medially at the eardrum, or **tympanic membrane**. The middle ear is an air-filled space in the temporal bone. It contains the auditory ossicles.

The **inner ear** holds the sensory organs for hearing and balance. The inner ear consists of interconnecting tunnels and chambers in the *bony labyrinth*. Inside the bony labyrinth is another set of membranous tunnels and chambers called the *membranous labyrinth*. This labyrinth is filled with a clear fluid called *endolymph*. The space between the membranous and bony labyrinths is filled with a fluid called *perilymph*. These fluids are similar to cerebrospinal fluid.

The **auricle** is shaped to collect sound waves. It directs sound waves toward the external auditory meatus. From the meatus, sound waves travel through the auditory canal

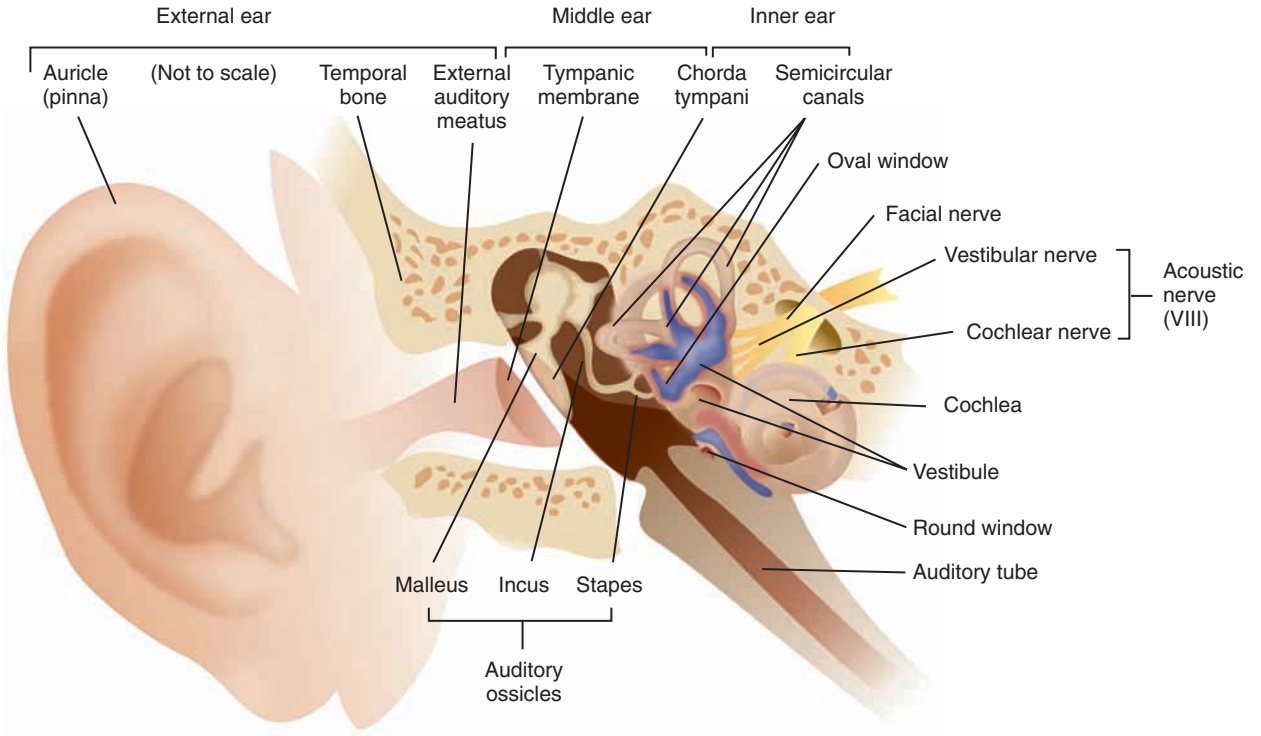

FIGURE 10-66 External, middle, and inner ear.

to the tympanic membrane, causing the membrane to vibrate.

The **middle ear** is connected to the inner ear by two membrane-covered openings. These are the *round window* and the *oval window*. Two other openings that are not covered by membranes offer a passageway for air from the middle ear. One opens into the *mastoid air cells*. The second opening, the auditory (or eustachian) tube, opens into the pharynx. The **eustachian tube** allows the equalization of air pressure between the outside air and the middle ear cavity. (Children have shorter eustachian tubes. Consequently, bacteria can travel more easily from infected areas in the throat to the middle ear. This difference between children and adults is responsible for the increased frequency of earaches and ear infections in children.) The auditory ossicles of the middle ear (called the *malleus*, *incus*, and *stapes*) transmit vibrations from the tympanic membrane to the oval window.

CRITICAL THINKING

Besides pain and impaired hearing, what other symptom would you look for in a patient with an inner ear problem?

The **bony labyrinth** of the inner ear is divided into three regions. These are called the *vestibule,* the *cochlea,* and the *semicircular canals*. The vestibule and semicircular canals are involved primarily in balance. The cochlea is involved in hearing. The hearing sense organ, which lies inside the cochlea, is called the *organ of Corti*. In young, healthy individuals, the frequencies that can be detected by the ear range (over octaves) from 20 to 20,000 cycles per second.

SUMMARY

- The paramedic must understand human anatomy fully. This understanding helps the paramedic organize a patient assessment by body region. Knowledge of anatomy also helps the paramedic communicate well with medical direction and other members of the health care team.
- The anatomical position refers to a person standing erect with the feet and palms facing the examiner.
- Directional terms are expressed in anatomical terminology. Examples of these are *up* or *down* (superior or inferior) *front* or *back* (anterior or posterior), and *right* or *left*. These terms always refer to the patient, not the examiner. Internal body structure is classified into anatomical planes of the human body. These planes can be thought of as imaginary straight-line divisions.
- The appendicular region of the body includes the limbs, or extremities. The axial region consists of the head, neck, thorax, and abdomen.
- The abdomen usually is divided into four quadrants: upper right, lower right, upper left, and lower left.
- The three major cavities of the human body are the thoracic cavity, the abdominal cavity, and the pelvic cavity.
- The thoracic cavity contains the trachea, esophagus, thymus, heart, great vessels, lungs, and the cavities and membranes that surround them. The abdominopelvic cavity is surrounded by membranes and contains organs and blood vessels.
- The cytoplasmic membrane encloses the cytoplasm. The membrane forms the outer boundary of the cell.
- Cytoplasm lies between the cytoplasmic membrane and the nucleus. Specialized structures in the cell (organelles) are located in the cytoplasm. These organelles perform functions that are vital to the cell's survival. The nucleus is a large, membrane-bound organelle. It ultimately controls all other organelles in the cytoplasm.
- All human cells, except for the reproductive (sex) cells, reproduce by a process known as *mitosis*. In this process, cells divide to multiply.
- Four main types of tissue make up the many organs of the body: epithelial tissue, connective tissue, muscle tissue, and nervous tissue. Epithelial tissue covers surfaces and forms structures. Connective tissue is made of cells separated from each other by intercellular material. This material is known as the *extracellular matrix*. Muscle tissue is contractile tissue and is responsible for movement. Nervous tissue has the ability to conduct electrical signals, known as *action potentials*.
- A *system* is a group of organs arranged to perform a more complex function than any one organ can perform alone. The eleven major organ systems in the body are the integumentary, skeletal, muscular, nervous, endocrine, circulatory, lymphatic, respiratory, digestive, urinary, and reproductive systems.
- The integumentary system consists of the skin and accessory structures such as the hair, nails, and a variety of glands. The functions of the integumentary system include protecting the body against injury and dehydration, defending against infection, and regulating temperature.
- The skeletal system consists of bone and associated connective tissues, including cartilage, tendons, and ligaments. The skeletal system provides a rigid framework for support and protection. It also provides a system of levers on which muscles act to produce body movements.
- The three primary functions of the muscular system are movement, postural maintenance, and heat production.
- The nervous system and the endocrine system are the major regulatory and coordinating systems of the body. The nervous system rapidly sends information. It does

Continued

this by means of nerve impulses conducted from one area of the body to another. The endocrine system sends information more slowly. It does this by means of chemicals secreted by ductless glands into the bloodstream.

- The heart and cardiovascular system are responsible for circulating blood throughout the body. Blood performs many important functions: it transports nutrients and oxygen to tissues; it carries carbon dioxide and waste products away from tissues; it carries hormones produced in endocrine glands to their target tissues; it plays a key role in temperature regulation and fluid balance; and it protects the body from bacteria and foreign substances.
- The lymphatic system is made up of lymph, lymphocytes, lymph nodes, tonsils, spleen, and thymus gland. The lymphatic system has three basic functions: to help maintain fluid balance in tissues; to absorb fats and other substances from the digestive tract; and to play a role in the body's immune defense system.
- The organs of the respiratory system and the cardiovascular system move oxygen to cells. They move carbon dioxide from cells to the locations where it is released into the air. The entrance to the respiratory tract begins at the nasal cavity and includes the nasopharynx, oropharynx, laryngopharynx, and larynx. Below the glottis are the structures of the lower airway and lungs. These structures include the trachea, bronchial tree, alveoli, and lungs.
- The digestive system provides the body with water, electrolytes, and other nutrients used by cells. The gastrointestinal tract is an irregularly shaped tube. Associated accessory organs (mainly glands) secrete fluid into the digestive tract.
- The urinary system works with other body systems to maintain homeostasis. It does this by removing waste products from the blood. It also does this by helping to maintain a constant body fluid volume and composition. The urinary system comprises two kidneys, two ureters, the urinary bladder, and the urethra.
- The purpose of the male reproductive system is to make and transfer spermatozoa to the female. The purpose of the female reproductive system is to make oocytes and to receive the spermatozoa for fertilization, conception, gestation, and birth. The male reproductive system consists of the testes, epididymis, ductus deferens, urethra, seminal vesicles, prostate gland, bulbourethral glands, scrotum, and penis. The female reproductive organs consist of the ovaries, uterine (or fallopian) tubes, uterus, vagina, external genital organs, and mammary glands.
- Senses provide the brain with information about the outside world. Four senses are recognized as special senses: smell, taste, sight, and hearing and balance.

CHAPTER

11 General Principles of Pathophysiology

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the normal characteristics of the cellular environment and the key homeostatic mechanisms that strive to maintain an optimal fluid and electrolyte balance.
2. Outline pathophysiological alterations in water and electrolyte balance and list their effects on body functions.
3. Describe the treatment of patients with particular fluid or electrolyte imbalances.
4. Describe the mechanisms in the body that maintain normal acid-base balance.
5. Outline pathophysiological alterations in acid-base balance.
6. Describe the management of a patient with an acid-base imbalance.
7. Describe the changes in cells and tissues that occur with cellular adaptation, injury, neoplasia, aging, or death.
8. Outline the effects of cellular injury on local and systemic body functions.
9. Describe changes in body functions that can occur as a result of genetic and familial disease factors.
10. Outline the causes, adverse systemic effects, and compensatory mechanisms associated with hypoperfusion.
11. Describe the ways in which the inflammatory and immune mechanisms respond to cellular injury or antigenic stimulation.
12. Explain how changes in immune status and the presence of inflammation can adversely affect body functions.
13. Describe the impact of stress on the body's response to illness or injury.
14. Describe factors that influence disease.

KEY TERMS

acid A compound that yields hydrogen ions when dissociated in solution.

acid-base balance The body's balance between acidity and alkalinity.

acidosis A condition marked by a high concentration of hydrogen ions (i.e., a pH below 7.35).

active transport A carrier-mediated process that can move substances against a concentration gradient.

aerobic Of or pertaining to the presence of air or oxygen.

afterload The total resistance against which blood must be pumped; also known as peripheral vascular resistance.

aldosterone A steroid hormone produced by the adrenal cortex to regulate the sodium and potassium balance in the blood.

alkalosis A condition marked by a low concentration of hydrogen ions (i.e., a pH above 7.45).

allergens Substances that can produce hypersensitivity reactions in the body.

allergy A hypersensitivity reaction to intrinsically harmless antigens, most of which are environmental.

alpha-adrenergic receptor Any one of the postulated adrenergic components of receptor tissues that responds to norepinephrine and to various blocking agents.

ammonium ion The monovalent cation NH_4.

anaerobic Of or pertaining to the absence of oxygen.

anaphylaxis An exaggerated, life-threatening hypersensitivity reaction to a previously encountered antigen.

angiotensin I The inactive form of angiotensin, formulated by the stimulation of renin, which is converted to angiotensin II.

angiotensin II A potent vasoconstrictor that also acts to stimulate the secretion of antidiuretic hormone.

angiotensin-converting enzyme A circulating enzyme that participates in the body's renin-angiotensin system, which mediates extracellular volume and arterial vasoconstriction.

anion An ion with a negative charge.

antibody A substance produced by the body that destroys or inactivates a specific substance (antigen) that has entered the body.

antigens Substances (usually proteins) that cause the formation of an antibody and that react specifically with that antibody.

anuria The inability to urinate; the cessation of urine production; a diminished urinary output of less than 100 to 250 mL per day.

areflexia A neurological condition characterized by the absence of reflexes.

arteriovenous anastomosis A vessel that allows blood to flow from arteries to veins without passing through capillaries; also known as an *arteriovenous shunt*.

ascites An abnormal intraperitoneal accumulation of fluid containing large amounts of protein and electrolytes.

atherosclerosis A common arterial disorder characterized by yellowish plaques of cholesterol, lipids, and cellular debris in the inner layers of the walls of large and medium-sized arteries.

atrial natriuretic factor A peptide released from the atria when atrial blood pressure is increased; it lowers blood pressure by increasing urine production, thus reducing blood volume.

atrophy Decrease in size (shrinkage) of a cell, which adversely affects cell function.

autoimmunity An abnormal characteristic or condition in which the body reacts against constituents of its own tissues.

autolysis The spontaneous disintegration of tissues or cells by the action of their own autogenous enzymes.

B lymphocytes The lymphocytes responsible for antibody-mediated immunity.

base A chemical compound that combines with an acid to form a salt; also known as an alkali.

beta-adrenergic receptor Any of the postulated adrenergic components of receptor tissues that respond to epinephrine and various blocking agents.

bivalent cation An ion with two positive charges.

botulism An often fatal form of food poisoning caused by the bacillus *Clostridium botulinum*.

capillaries Tiny vessels that connect arterioles to venules.

capillary network A complex, interconnected structure where a single blood cell traveling from an arteriole to a venule via a capillary bed passes through capillary segments.

capsid A protein coat that encloses a virus.

carbonic acid An aqueous solution of carbon dioxide.

carbonic anhydrase The enzyme that converts carbon dioxide into carbonic acid.

cardiac output The volume of blood pumped each minute by the ventricles.

carrier molecule A protein that combines with solutes on one side of a membrane, transporting the solute to the other side; it is used in mediated transport mechanisms.

cathartic A substance that accelerates defecation.

cation An ion with a positive charge.

central nervous system ischemic response An increase in blood pressure caused by vasoconstriction that occurs when oxygen levels are too low, carbon dioxide levels are too high, or pH is too low in the medulla.

chemotactic factors Biochemical mediators that are important in activating the inflammatory response.

complement system A group of proteins that coat bacteria; the proteins then either help kill the bacteria directly or assist neutrophils (in the blood) and macrophages (in the tissues) to engulf and destroy the bacteria.

congenital Present at birth.

cortisol A steroid hormone that occurs naturally in the body.

cytochromes Proteins in the liver that play a role in drug detoxification.

dehydration An excessive loss of water from the body tissues; it may follow prolonged fever, diarrhea, vomiting, acidosis, and other conditions.

diabetes mellitus A complex disorder of carbohydrate, fat, and protein metabolism that primarily results from partial or complete lack of insulin secretion by the beta cells of the pancreas or occurs because of defects in the insulin receptors.

diffusion The process by which solid, particulate matter in a fluid moves from an area of higher concentration to an area of lower concentration, resulting in an even distribution of the particles in the fluid.

dysplasia Abnormal cellular growth.

dysrhythmia Variation from a normal rhythm.

edema The accumulation of fluid in the interstitial spaces.

endotoxin A toxin contained in the cell walls of some microorganisms, especially gram-negative bacteria.

exotoxin A toxin secreted or excreted by a living organism.

extracellular fluid The fluid found outside the cells, including that in the intravascular and interstitial compartments.

facilitated diffusion A carrier-mediated process that moves substances into or out of cells from a high to a low concentration.

glycolysis An anaerobic process during which glucose is converted to pyruvic acid.

hemodialysis A procedure in which impurities or wastes are removed from the blood; it is used in treating renal insufficiency and various toxic conditions.

hemoglobin A complex protein-iron compound in the blood that carries oxygen to the cells from the lungs and carbon dioxide away from the cells to the lungs.

hydrogen ion The acidic element in a solution.

hypercalcemia A higher than normal concentration of calcium in the blood.

hyperkalemia A higher than normal concentration of potassium in the blood.

hypermagnesemia A higher than normal concentration of magnesium in the blood.

hypernatremic A term describing a higher than normal concentration of sodium in the blood.

hypernatremic dehydration The loss of more water than sodium.

hyperphosphatemia High levels of alkaline phosphate in the blood.

hyperplasia An excessive increase in the number of cells.

hypersensitivity reaction An altered immunological response to an antigen that results in a pathological immune response upon reexposure.

hypertonic A term used to describe a solution that causes cells to shrink.
hypertrophy An increase in the size of a cell.
hypokalemia A lower than normal concentration of potassium in the blood.
hypomagnesemia A lower than normal concentration of magnesium in the blood plasma.
hyponatremic A term describing a lower than normal concentration of sodium in the blood.
hyponatremic dehydration The loss of more sodium than water.
hypoperfusion Severely inadequate circulation that results in insufficient delivery of oxygen and nutrients necessary for normal tissue and cellular function; also known as shock.
hypophosphatemia Low levels of alkaline phosphate in the blood.
hypotonic A term used to describe a solution that causes cells to swell.
hypotonicity of the muscles Decreased muscle tone or tension.
hypoxemia A lower than normal oxygen content of the blood as measured in an arterial blood sample.
immune response A defense function of the body that produces antibodies to destroy invading antigens and malignancies.
infarction Cell death.
inflammatory response A tissue reaction to injury or to an antigen; it may include pain, swelling, itching, redness, heat, and loss of function.
interstitial fluid Fluid that occupies the space outside the blood vessels and/or outside the cells of an organ or tissue.
intracellular fluid The fluid found in all body cells.
ischemia A state of insufficient perfusion of oxygenated blood to a body organ or part.
isoimmunity An immune response directed against beneficial foreign tissues.
isotonic A term used to describe a solution that causes cells neither to shrink nor to swell.
isotonic dehydration Excessive loss of sodium and water in equal amounts.
ketone bodies The normal metabolic products of lipid and pyruvate within the liver; excessive production leads to their excretion in urine.
Krebs cycle A sequence of enzymatic reactions involving the metabolism of carbon chains of sugar, fatty acids, and amino acids to yield carbon dioxide, water, and high-energy phosphate bonds.
lactate A salt of lactic acid.
lactic acidosis A disorder characterized by an accumulation of lactic acid in the blood, resulting in a lowered pH in muscle and serum.
leukocytosis An abnormal increase in the number of circulating white blood cells.
malaise A vague feeling of weakness or discomfort.
mast cells Specialized cells of the inflammatory response.
mediated transport mechanisms Mechanisms that use carrier molecules to move large, water-soluble molecules or electrically charged molecules across cell membranes.
membrane permeability A quality of cell membranes that permits the passage of solvents and solutes into and out of cells.
metaplasia A change from one cell type to another that is better able to tolerate adverse conditions; a conversion into a form that is not normal for that cell.
metarteriole One of the small peripheral blood vessels that contain scattered groups of smooth muscle fibers in their walls; they are located between the arterioles and the true capillaries.
multiple organ dysfunction syndrome The progressive failure of two or more organ systems after a severe illness or injury.
necrosis Death of a cell or group of cells as the result of disease or injury.
negative feedback mechanisms Mechanisms that tend to produce a response that balances a change in a system.
neoplasia New and abnormal development of cells, which may be benign or malignant.
nonelectrolyte A substance with no electrical charge.
oliguria A diminished capacity to form or pass urine.
osmolality The osmotic pressure of a solution.
osmosis The diffusion of solvent (water) through a membrane from a less concentrated solution to a more concentrated solution.
osmotic pressure The force required to prevent the movement of water across a selectively permeable membrane.
overhydration Water excess or water intoxication.
paresthesia A sensation of numbness, tingling, or "pins and needles."
partial pressure The pressure exerted by a single gas.
pathophysiology The abnormal functions and diseases of the human body.
peripheral vascular resistance The total resistance against which blood must be pumped; also known as afterload.
pH An inverse logarithm of the hydrogen ion concentration.
phagocytosis The process of ingestion by cells of solid substances such as other cells, bacteria, bits of necrosed tissue, and foreign particles.
pitting edema Observable indentation of body tissues that persists after applying pressure to an area swollen from fluid accumulation.
polyuria Excessive secretion of urine.
postcapillary sphincter The smooth muscle sphincter at the venous end of a capillary that regulates blood flow through the capillary.
precapillary sphincter The smooth muscle sphincter at the arterial end of a capillary that regulates blood flow through the capillary.
preload The amount of blood returning to the ventricle.
renin A proteolytic enzyme that surrounds each arteriole as it enters a glomerulus; it affects blood pressure

by catalyzing the change of angiotensin I to angiotensin II.

respiratory acidosis An abnormal condition characterized by an increased arterial P_{CO_2}, excess carbonic acid, and an increased plasma hydrogen ion concentration.

respiratory alkalosis An abnormal condition characterized by decreased P_{CO_2}, decreased hydrogen ion concentration, and increased blood pH.

Rh factor An antigenic substance present in the erythrocytes of most persons; a person lacking the Rh factor is Rh negative.

semipermeable membrane A membrane that allows some fluids and substances to pass through it but not others, usually dependent on size, shape, electrical charge, or other chemical properties of the substance or fluid.

shock A condition of severely inadequate blood flow to the body's peripheral tissues that is associated with life-threatening cellular dysfunction; also known as hypoperfusion.

solutes Substances dissolved in solution.

Starling hypothesis The concept that describes the movement of fluid across the capillary wall (net filtration).

stroke volume The volume of blood ejected from one ventricle in a single heartbeat.

T lymphocytes The lymphocytes responsible for cell-mediated immunity.

tetany The involuntary contraction of skeletal muscles.

toxic shock syndrome A severe, acute disease caused by infection with strains of *Staphylococcus aureus.*

toxoid A toxin that has been treated with chemicals or with heat to reduce its toxic effects but that retains its antigenic power.

virulence The relative strength of a pathogen.

Chapter 10 described anatomy and physiology—the structure and function of the human body. This chapter discusses pathophysiology—the abnormal functions and diseases of the human body. Paramedics need to understand the physical and biological principles of disease. This will help them to anticipate, direct, and provide appropriate care to their patients.

SECTION ONE
Cellular Physiology

BASIC CELLULAR REVIEW

As discussed in Chapter 10, the cell is the basic unit of higher life forms. All cells have various key components and structures. These include *cell membranes,* membranes that isolate individual cells and separate each cell's internal (cellular) environment from its external environment, and *enzymes,* proteins that mediate biochemical processes. Other key components and structures are the *internal membranes* that encapsulate chemicals, and the genetic material for replication. Cells form the four basic types of tissue:

- Epithelial tissue
- Connective tissue (including hematological tissue)
- Muscle tissue
- Nervous tissue

CELLULAR ENVIRONMENT

The cells of the human body live in a fluid environment that consists mainly of water. Body water is essential for two reasons. First, it is the medium in which all metabolic reactions occur. Second, the body's health depends on precise regulation of the volume and composition of this fluid. The body has two fluid compartments: the intracellular fluid and the extracellular fluid (Figure 11-1).

Intracellular and Extracellular Fluid

Intracellular fluid (ICF) is the fluid found inside all body cells. It accounts for 40% of total body weight. **Extracellular fluid** (ECF) is the fluid found outside the cells. This includes the intravascular and interstitial compartments. ECF accounts for about 20% of total body weight, with the intravascular component (blood plasma) composing about

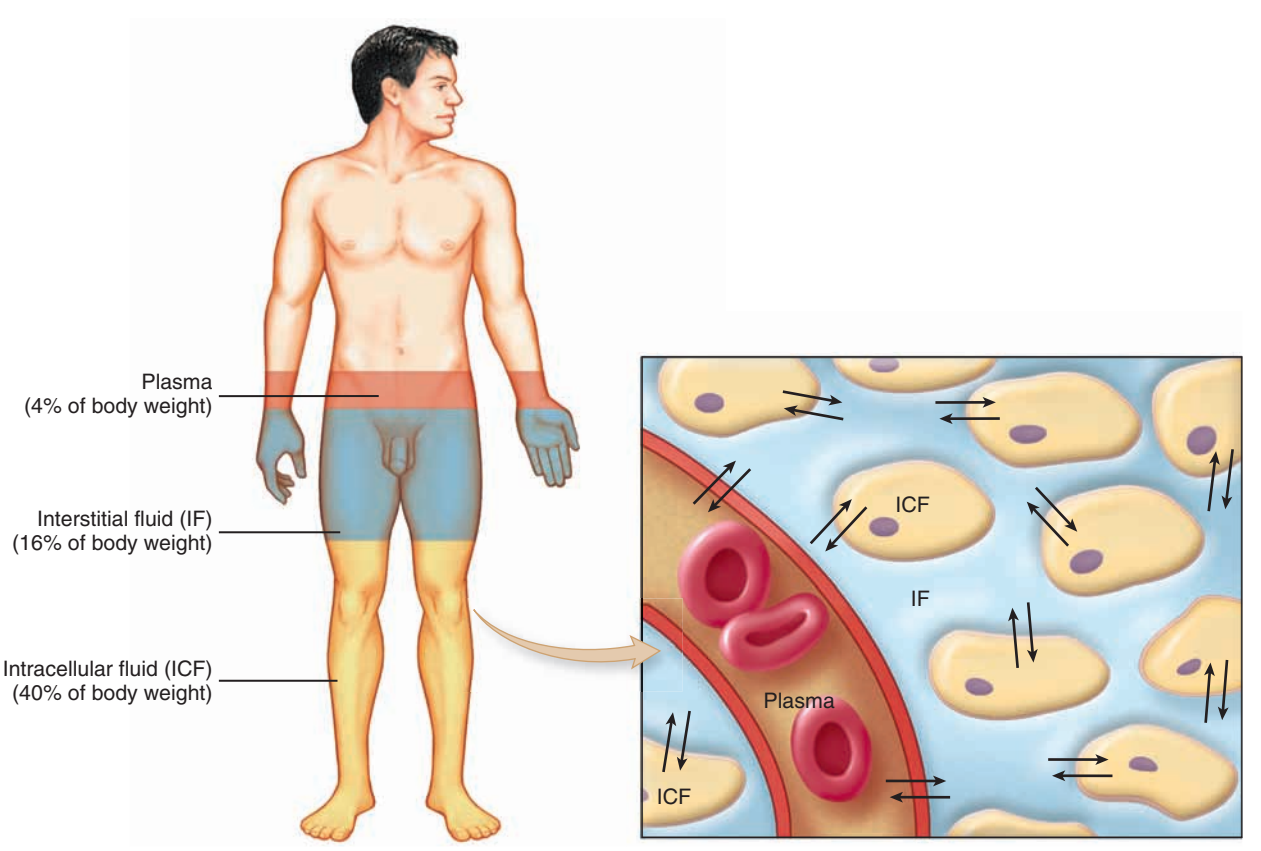

FIGURE 11-1 Fluid compartments of the body.

one third. The extracellular fluid between the cells and outside the vascular bed (i.e., connective tissue, cartilage, and bone) is known as **interstitial fluid** (IF). This category also includes special fluids, such as cerebrospinal fluid and intraocular fluid. The IF accounts for about 15% to 16% of total body weight.

Aging and the Distribution of Body Fluids

Body mass consists mainly of water. In fact, water accounts for 50% to 60% of total body weight in adults. The distribution and amount of total body water (TBW) vary according to age. For example, about 80% of a newborn infant's body weight is TBW. During childhood, TBW decreases to 60% to 65% of body weight, and it declines further with age (Table 11-1). TBW in the elderly decreases to 45% to 55%, increasing the risk of dehydration and electrolyte abnormalities (see Chapter 49).

NOTE
In older adults the normal reduction in total body water (TBW) becomes a significant factor if fever or dehydration is present. With illness or injury, loss of body fluids can be severe or life-threatening.

TABLE 11-1 Total Body Water (TBW) Relative to Body Type

Body Build	Adult Male (% TBW)	Adult Female (% TBW)	Infant (% TBW)
Normal	60	50	70
Lean	70	60	80
Obese	50	42	60

Water Movement Between Intracellular Fluid and Extracellular Fluid

Body fluids constantly move from one compartment to another. In healthy individuals, the volume in each compartment remains about the same. To keep the volume stable, the body uses **osmosis, diffusion,** and **mediated transport mechanisms.** To understand illness and disease, the paramedic first must understand how fluids in the body move and how changes in these fluids can occur.

OSMOSIS

For the body to function well, molecules must be able to move within a cell or across cell membranes. Membranes separate fluid compartments. Most of these membranes

allow water to pass freely. They also regulate the flow of **solutes** (substances dissolved in solution) on the basis of size, shape, electrical charge, or other chemical properties. These membranes are referred to as **semipermeable membranes.** *Channels* in these membranes permit the passage of solutes. The channels may be open at all times to specific solutes, or they may be closed at times, depending on the cell's composition. Because the cell membrane can regulate the flow of solutes, the cell can maintain **homeostasis** (stability in the body's internal environment).

Osmosis is the diffusion or spreading of water molecules across a semipermeable membrane from a lower solute concentration to a higher solute concentration. (Figure 11-2). Osmosis separates two solutions of different concentrations by blocking the transport of salts or other solutes. The pressure that prevents the flow of fluid across a semipermeable membrane is **osmotic pressure;** it is the pressure required to maintain cellular equilibrium. Osmotic pressure depends on two factors: (1) the number and molecular weight of particles on each side of the cell membrane and (2) the **membrane permeability** to these particles.

NOTE

With gases, the driving force of osmosis is produced by the partial pressures of the dissolved gases (such as oxygen, nitrogen, carbon dioxide) and water. In any mixture of gases, the combination of the pressures exerted by all the gases is the **total pressure.** The pressure exerted by a single gas is the **partial pressure.** The partial pressure of a gas in a mixture is denoted by the letter "P" preceding the gas (e.g., the partial pressure of oxygen [P_{O_2}] or the partial pressure of carbon dioxide [P_{CO_2}]) (see Chapter 15).

When a living cell is placed in a solution that has a higher solute concentration (and a lower water concentration) than that inside the cell, the solution is called a **hypertonic** solution. When the cell is placed in this solution, the osmotic pressure exerted on it produces a net movement of water out of the cell. This causes the cell to dehydrate, shrink, and possibly die.

NOTE

Electrolytes are salt substances whose molecules dissociate into charged components when in water, producing positively and negatively charged ions. An **ion** with a positive charge is called a **cation.** An ion with a negative charge is called an **anion.** Sodium is the most abundant cation in the extracellular fluid (ECF). It is responsible for the osmotic balance of the ECF space. Potassium is the most abundant cation in the intracellular fluid (ICF). It maintains the osmotic balance of the ICF space. The body also has **nonelectrolytes** (substances with no electrical charge), such as glucose and urea.

Likewise, when a living cell is placed in a solution that has a lower solute concentration (and a higher water concentration) than that inside the cell, the solution is called a **hypotonic** solution. Osmotic pressure draws water from the solution into the cell. The net movement of water into the cell causes it to swell and possibly burst (**lyse**).

A cell may be placed in a solution that has the same solute and water concentrations as the solution inside the cell. This solution is called **isotonic.** Isotonic solutions have no net movement of water molecules (Figure 11-3 and Box 11-1).

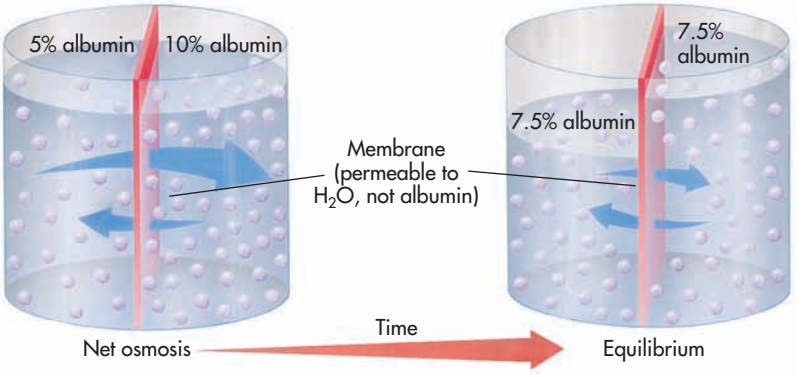

FIGURE 11-2 Osmosis. Osmosis is the diffusion of water through a selectively permeable membrane. The membrane shown in this diagram is permeable to water but not to albumin. Because there are relatively more water molecules in 5% albumin than in 10% albumin, more water molecules osmose from the more dilute into the more concentrated solution (as indicated by the *large arrow* in the diagram on the left) than osmose in the opposite direction. The overall direction of osmosis, in other words, is toward the more concentrated solution. Movement across the membrane continues until the concentrations of the solution equalize.

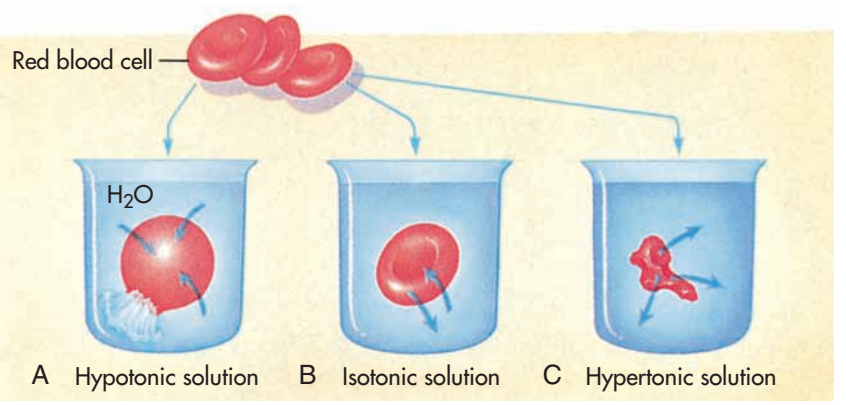

FIGURE 11-3 Effects of hypotonic, isotonic, and hypertonic solutions on red blood cells. **A,** The *hypotonic solution,* which has a low ion concentration, causes swelling and lysis of the cells. **B,** In the *isotonic solution,* which has a normal ion concentration, the cells keep their normal shape. **C,** The *hypertonic solution,* which has a high ion concentration, causes shrinkage (*crenation*) of the cells.

BOX 11-1 Fluid Replacement Therapy

Intravenous therapy is based on hypertonic, hypotonic, and isotonic properties.

Hypotonic Solutions

A *hypotonic solution* has a lower solute concentration than that of normal cells. When a hypotonic solution is infused into a normally hydrated patient, water is drawn from the solution into the cells. Hypotonic solutions supply the patient with calories. They also replenish salt and water. They are used to hydrate patients. They are used to prevent dehydration as well. An example of a hypotonic solution is 2.5% dextrose in water. Another is 0.45% normal saline (½NS). Although technically isotonic (see below), 5% dextrose in water (D_5W) acts physiologically as a hypotonic solution. This is because the solute (glucose) is actively transported into cells, leaving excess free water behind.

Isotonic Solutions

In an *isotonic solution,* the concentration of solute molecules is the same as that found in most normal cells. When an isotonic solution is infused into a normally hydrated patient, water is neither drawn out of the cells nor moved into them. Rather, water stays in the vascular space. Isotonic solutions are usually given to replace extracellular fluid. This fluid may have been depleted as a result of blood loss or severe vomiting. In fact, an isotonic solution may be prescribed for any patient in whom the chloride loss equals or exceeds the sodium loss. An example of an isotonic solution is 0.9% normal saline. Another is lactated Ringer's solution.

Hypertonic Solutions

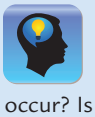
A *hypertonic solution* has a higher concentration of solute molecules than that found in normal cells. When a hypertonic solution is infused into a normally hydrated patient, it draws water from the cells into the vascular space. Examples of hypertonic solutions are mannitol (Osmitrol), sodium bicarbonate, and 50% dextrose (D_{50}).

These solutions are often used to treat cerebral edema (mannitol), metabolic acidosis (bicarbonate), and profound hypoglycemia (50% dextrose). In addition, recent studies have suggested that some hypertonic solutions (e.g., Dextran, hetastarch, and sodium chloride [3%, 5%, and 7.5%, respectively]) should be used for volume restoration after trauma.[3] By drawing tissue fluid into the vascular space, hypertonic solutions may reduce both the volume of the infusion and the development of pulmonary problems after resuscitation.

DIFFUSION

Diffusion is a result of the constant motion of all the atoms, molecules, or ions in a solution. It is a passive process in which molecules or ions move from an area of higher concentration to an area of lower concentration (Figure 11-4). An area of high concentration has more solute particles than an area of low concentration. More solute particles move from the higher concentration to the lower one. Once at *equilibrium,* the movement of solutes in one direction is balanced by equal movement in the opposite direction.

The concentration of a solute may be greater at one point in the solvent than it is at another point. This means that a **concentration gradient** exists. Solutes diffuse *down* their concentration gradients from high to low concentration until equilibrium is achieved. Some nutrients enter and some waste products leave the cell by diffusion. Maintenance of the proper intracellular concentrations of certain substances depends on this process.



CRITICAL THINKING

What happens to a raisin that is put into a cup of water and left there for an hour? Why does this change occur? Is the water hypotonic, hypertonic, or isotonic relative to the inside of the raisin? Does a concentration gradient exist?

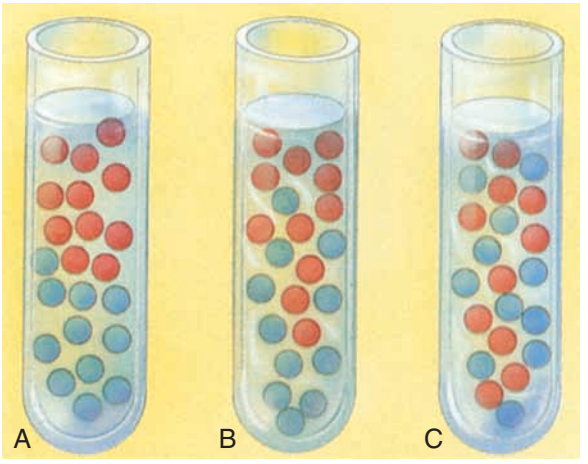


FIGURE 11-4 Diffusion. **A,** A solution (red, representing one type of molecule) is layered onto another solution (blue, representing a second type of molecule). A concentration gradient exists that favors the passage of red molecules into the blue solution, because the blue solution has no red molecules. Likewise, a concentration gradient exists that favors the passage of blue molecules into the red solution, because the red solution has no blue molecules. **B,** Red molecules move with their concentration gradient into the blue solution, and the blue molecules move with their concentration gradient into the red solution. **C,** Red and blue molecules are distributed evenly throughout the solution. Even though the red and blue molecules continue to move randomly, equilibrium exists. This means that no net movement occurs because no concentration gradient exists.

MEDIATED TRANSPORT MECHANISMS

A number of vital molecules (e.g., glucose) cannot enter most cells by diffusion. Also, a number of products (e.g., some proteins) cannot exit most cells by diffusion. *Mediated transport mechanisms* are required to move large, water-soluble molecules or electrically charged molecules across the cell membranes. These mechanisms use carrier molecules. **Carrier molecules** are proteins that combine with solute molecules on one side of a membrane. They then change shape, pass through the membrane, and release the solute molecule on the other side (Figure 11-5).

Carrier-mediated transport can be divided into two types: active transport and facilitated diffusion. **Active transport** moves substances *against* a concentration gradient, from *areas of lower concentration to areas of higher concentration*. The cell must expend energy to work against this concentration gradient. Active transport occurs at a faster rate than diffusion.

Facilitated diffusion moves substances into and out of cells from an *area of higher concentration to an area of lower concentration*. For these materials, the direction of movement is *with* the concentration gradient. As with active transport, this movement occurs more quickly than in normal diffusion. However, unlike in active transport, facilitated diffusion does not require the cell to expend energy. The moving force in facilitated diffusion is a downhill concentration gradient.

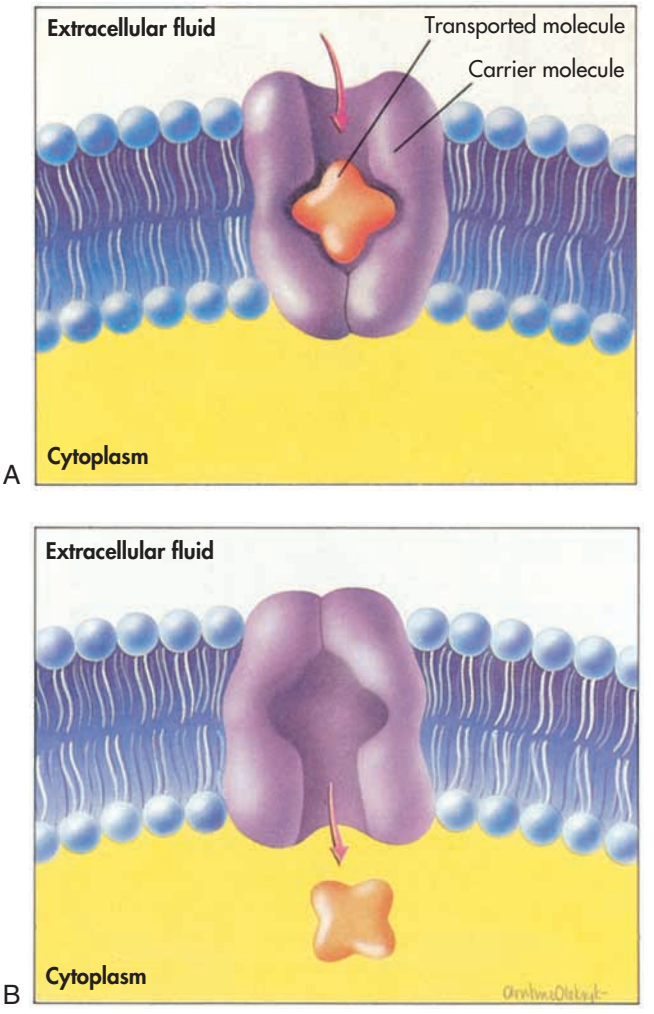

FIGURE 11-5 Mediated transport by a carrier molecule. **A,** The carrier molecule binds with a molecule on one side of the plasma membrane and changes shape. **B,** The molecule is released on the other side of the plasma membrane.

Water Movement Between Plasma and Interstitial Fluid

Fluid is transferred between the circulating blood and the interstitial fluid as a result of pressure changes. These changes occur at the arterial and venous ends of the capillary. The human body has about 10 billion capillaries. Few of the body's functional cells are farther than $^{5}/_{1000}$ inch (20 to 30 micrometers) from a capillary.

ANATOMY OF THE CAPILLARY NETWORK

A **capillary** is a thin-walled tube of endothelial cells. Capillaries do not have elastic or connective tissue or smooth muscle that would impede the transfer of water and solutes. Blood enters the capillary network from the arterioles. It flows through the **capillary network** and into the venules. The ends of the capillaries closest to the arterioles are *arteriolar capillaries*. The ends closest to the venules are *venous*

capillaries. The exchange of nutrients and metabolic end products takes place at the capillary level.

The arterioles lead directly to capillaries. In some tissues the **arterioles** give rise to metarterioles. The metarterioles then give rise to capillaries. As described in Chapter 10, most tissues appear to have two distinct types of capillaries: *true capillaries* and *thoroughfare channels*. From a metarteriole, blood may flow into a thoroughfare channel that connects arterioles and venules directly, bypassing the true capillaries. Blood flow through thoroughfare channels is relatively constant. From the thoroughfare channels, fluid commonly exits and reenters the network of true capillaries.

LOOK AGAIN
See Chapter 10: Human Systems, pp. 186-188.

The capillaries of some tissues have small cuffs of smooth muscle. These cuffs, which encircle the proximal and distal portions of the capillary, are known as *capillary sphincters*. The sphincter at the arterial end is known as the **precapillary sphincter.** The sphincter at the venous end is known as the **postcapillary sphincter.** These sphincters control capillary blood flow by opening and closing the entrance and exit to the capillary. Blood flow in true capillaries is not uniform. It depends on the contractile state of the arterioles and the precapillary and postcapillary sphincters (if present).

The blood flow through the capillaries that provides the exchange of gases and solutes between blood and tissue is referred to as *nutritional flow*. Blood that bypasses the capillaries in traveling from the arterial to the venous side of the circulation is known as *nonnutritional,* or *shunt flow*. True **arteriovenous anastomoses** (AV shunts) occur naturally in the sole of the foot, the palm of the hand, the terminal phalanges, and the nail bed. These shunts are important for the regulation of body temperature. Some evidence suggests the presence of AV shunts upstream from the capillary sphincters.[1]

Sympathetic fibers innervate all blood vessels of the body, except for the capillaries, the capillary sphincters, and most metarterioles. Sympathetic innervation of blood vessels includes both *vasoconstrictor* and *vasodilator* (vasomotor) fibers. However, the vasoconstrictor fibers are the most important in regulating blood flow. During normal circulation in the healthy body when arterial blood pressure is adequate, arterioles are open (though with some vasomotor tone), AV shunts are closed, and about 20% of the capillaries are open at any given time (Figure 11-6).

Diffusion Across the Capillary Wall. Tissue cells do not exchange material directly with blood. The interstitial fluid always acts as a "middle man." Nutrients must diffuse across the capillary wall into the interstitial fluid to enter cells. Metabolic end products, such as carbon dioxide and lactic acid, first must move across cell membranes into interstitial fluid to diffuse into the plasma.

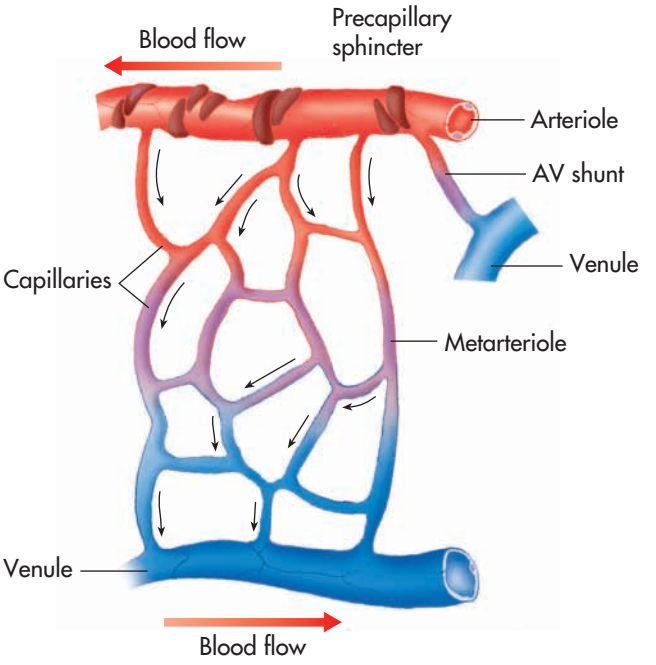

FIGURE 11-6 Microcirculation. The circular structures on the arteriole and venule represent smooth muscle fibers; branching solid lines represent sympathetic nerve fibers. The arrows indicate the direction of blood flow.

At the arteriole end of the capillary, the forces moving fluid out of the capillary are greater than the forces attracting fluid into it. At the venous end, these forces are reversed. Thus more fluid is attracted into the capillary at the venous end. Hydrostatic and osmotic pressures are the two forces responsible for this movement of fluid. The hydrostatic pressure (created with each heartbeat) forces water out of the arterial end of the capillary. The osmotic pressure results from the presence of plasma proteins (mostly albumin), which are too large to pass through the wall of the capillary; this pressure is referred to as *blood colloid osmotic pressure* or *oncotic pressure*.

At the venous end of the capillary, the hydrostatic pressure is lower. The concentration of proteins in the capillary increases slightly. This occurs because of the movement of fluid out of the arteriolar end. The result is a greater plasma protein concentration and a greater colloid osmotic pressure. Consequently, nearly all the fluid that leaves the capillary at its arteriolar end reenters the capillary at its venous end. The remaining fluid enters the lymphatic capillaries. Eventually it is returned to the general circulation. The movement of fluid across the capillary wall is called *net filtration*. It is best described by the **Starling hypothesis:**[2]

$$\text{Net filtration} = \text{Forces favoring filtration} - \text{Forces opposing filtration}$$

The forces favoring filtration include capillary hydrostatic pressure and the interstitial oncotic pressure. The forces opposing filtration are the plasma oncotic pressure and the interstitial hydrostatic pressure.

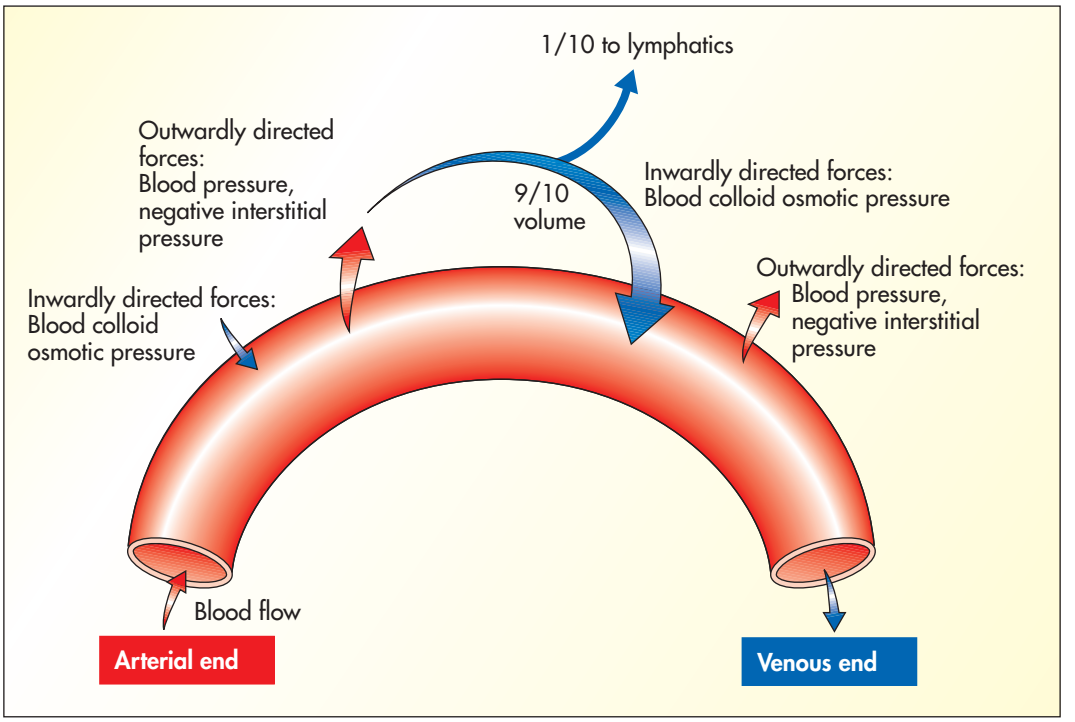

FIGURE 11-7 Total pressure differences between the inside and the outside of the capillary at its arteriolar and venous ends. At the arteriolar end, the sum of the forces causes fluid to move from the capillaries into the tissues. At the venous end, the sum of the forces attracts fluid into the capillary.

Fluid also may be exchanged across the capillary wall as a result of the cyclic dilation and constriction of the precapillary sphincter. When this sphincter dilates, the pressure rises in the capillary. This forces fluid to move into the interstitial spaces. When the precapillary sphincter constricts, the pressure in the capillary drops. Thus fluid moves into the capillary (Figure 11-7).

CAPILLARY AND MEMBRANE PERMEABILITY

A key factor in the movement of fluid across the capillary wall is the integrity of the capillary membrane. Changes in membrane permeability may allow plasma proteins to escape into the interstitial space. The resultant increase in interstitial oncotic pressure changes the relationship defined by the Starling hypothesis. It leads to osmotic movement of water into the interstitial space. This, in turn, results in tissue edema.

Alterations in Water Movement

Edema is the accumulation of fluid in the interstitial spaces. It can be caused by any condition that leads to a net movement of fluid out of capillaries and into the interstitial tissues. Edema is a problem of *fluid distribution*. It does not always indicate a *fluid excess*.

PATHOPHYSIOLOGY OF EDEMA

Normal flow of fluid through the interstitial spaces depends on the following four factors:

1. The capillary hydrostatic pressure that filters fluid from the blood through the capillary wall
2. The oncotic pressure exerted by the proteins in the blood plasma, which attracts fluid from the interstitial space back into the vascular compartment
3. The permeability of the capillaries, which determines how easily fluid can pass through the capillary wall
4. The presence of open lymphatic channels, which collect some of the fluid forced out of the capillaries by the hydrostatic pressure of the blood and return the fluid to the circulation

When any of these four factors is disturbed, changes in water movement can develop. The mechanisms most often responsible for edema are (1) an increase in the hydrostatic pressure, (2) a decrease in the plasma oncotic pressure, (3) an increase in capillary permeability, and (4) lymphatic obstruction.

Increased Capillary Hydrostatic Pressure. An increase in hydrostatic pressure can be caused by venous obstruction or sodium and water retention. With venous obstruction, the hydrostatic pressure of fluid in the capillaries can become great enough to cause fluid to escape into the interstitial spaces. Conditions that can lead to venous obstruction and edema include **thrombophlebitis** (the formation of a blood clot and inflammation in a vein), chronic venous disease, hepatic obstruction (blockage of hepatic veins or common bile duct), tight clothing around an extremity, and prolonged standing.

Sodium and water retention can cause an increase in circulating fluid volume (volume overload) and edema. *Congestive heart failure* (CHF) and *renal failure* are two conditions associated with sodium and water retention.

Decreased Plasma Oncotic Pressure. Decreases in plasma albumin concentration lead to a decrease in the plasma oncotic pressure. As a result, fluid moves into the interstitial space. This condition most often results from liver disease or protein malnutrition.

Increased Capillary Permeability. Increases in capillary permeability result in greater than normal filtration of fluid into the interstitial space. This condition usually is associated with allergic reactions. It also is linked to inflammation and the immune response triggered by trauma. (The immune response is described later in this chapter.) Examples of such trauma are burns or crushing injuries. In such cases, proteins escape from the vascular bed. As a consequence, the capillary oncotic pressure decreases, and the fluid oncotic pressure increases. The result is edema.

Lymphatic Obstruction. When lymphatic channels are blocked by infection or are surgically removed, proteins and fluid can accumulate in the interstitial space. This obstruction blocks the normal pathway by which fluid is returned from the interstitial space into the circulation. This leads to edema in the region that normally is drained by the lymphatic channels. Conditions that can cause obstruction in the channels include certain malignancies and parasitic infections, and the surgical removal of lymphatics. Surgical removal may occur after a radical mastectomy (surgical removal of an entire breast), which requires removal of the axillary lymph nodes.

CLINICAL MANIFESTATIONS OF EDEMA

Edema may be localized or generalized. *Localized edema* usually is limited to an injury site or an organ system. For example, an injury site may be a sprained ankle. An affected organ system may be the brain (*cerebral edema*) or the lungs (*pulmonary edema*). Edema of specific organs such as the brain, lungs, or larynx can threaten life.

Generalized edema is more widespread. It is most obvious in dependent parts of the body. It usually is noted first in the legs and ankles when the individual is standing or sitting. It is noted in the sacrum and buttocks when the person is lying down. Generalized edema usually causes weight gain, swelling, and puffiness. It is often linked to other symptoms caused by an underlying illness. In industrialized countries, the diseases that most often cause generalized edema are heart disease, kidney disease, and liver disease. In developing countries, the most common causes are malnutrition and parasitic disease.[3] When edematous tissue is compressed with a finger (e.g., over the ankle or tibia), the fluid is pushed aside, leaving a "pit" or indentation that gradually refills with fluid. This condition is called **pitting edema** (Box 11-2). The accumulation of fluid in the peritoneal cavity is a condition called **ascites.**

BOX 11-2 Pitting Edema Scale

+1 Minor pitting of the skin without visible deformation; depression disappears quickly.
+2 No obvious distortion of the skin; depression typically normalizes within 10 to 15 seconds.
+3 Noted deformity of the skin; depression produces a definite pit that persists longer than 1 minute.
+4 Obvious gross deformity of the skin; depression produces a very deep pit that persists longer than 2 minutes.

CRITICAL THINKING

The rest, ice, compression, and elevation (RICE) treatment is used for swelling from a sprained ankle. Why does this treatment reduce tissue edema?

Water Balance, Sodium, and Chloride

Water follows the osmotic gradient established by changes in the sodium concentration. Hence sodium and water balance are closely related.

WATER BALANCE

Water balance is mainly regulated by antidiuretic hormone (ADH) (see Chapter 10). The secretion of ADH and the perception of thirst help regulate water balance. Release of ADH is triggered by an increase in the plasma **osmolality** (the osmotic pressure of a solution). It also may be triggered by a decrease in the circulating blood volume and a decline in venous and arterial pressures. An increase in plasma osmolality stimulates hypothalamic neurons (called *osmoreceptors*). This causes the individual to feel thirsty. It also increases the release of ADH from the posterior pituitary gland.

In response to the release of ADH, water is reabsorbed into the plasma from the distal renal tubules and collecting ducts of the kidneys. This reduces the amount of water lost in the urine. Also, as the water is reabsorbed, the plasma osmolality decreases, returning to normal. Volume-sensitive receptors, as well as pressure-sensitive receptors (*baroreceptors,* which are found in the heart and great vessels), also can stimulate the release of ADH when body fluids are depleted. These fluids may be lost from conditions such as vomiting, diarrhea, or excess sweating.

NOTE

Volume-sensitive receptors and baroreceptors are nerve endings that are sensitive to changes in volume and pressure, respectively. Volume-sensitive receptors are located in the right and left atria and the thoracic vessels. Baroreceptors are found in the aorta, pulmonary arteries, and carotid sinus.

SODIUM AND CHLORIDE BALANCE

As mentioned before, sodium is the major ECF cation. Sodium balance is regulated by **aldosterone.** (Aldosterone is a hormone secreted by the adrenal cortex.) Along

with chloride and bicarbonate, sodium regulates osmotic forces. Hence, it regulates water balance. (Chloride is the major ECF anion. It provides electroneutrality in relation to sodium. Increases or decreases in chloride concentration occur in proportion to changes in sodium concentration.)

Secretion of aldosterone is triggered by a decrease in sodium levels. It also is triggered by an increase in potassium levels. Aldosterone causes the distal tubules of the kidneys to increase both the reabsorption of sodium and the secretion of potassium.

The enzyme **renin** also is secreted by the kidneys. This occurs when the circulating blood volume is reduced or the sodium-water balance is disrupted. Renin stimulates the formation of **angiotensin I.** This is then changed to **angiotensin II.** Angiotensin II is a potent vasoconstrictor. It acts to stimulate the secretion of ADH, which results in the reabsorption of sodium and water. It also results in an increase in the systemic blood pressure. (This is described later in the chapter.) This mechanism for regulating levels of sodium and water is known as the *renin-angiotensin-aldosterone system* (Figure 11-8).

Natriuretic hormone also helps to regulate sodium concentration. It does this by promoting the secretion of sodium in the urine. One result is a decrease in tubular reabsorption of sodium. Another result is a subsequent loss of sodium and water. **Atrial natriuretic factor** is a substance released from the atrial cells of the heart. (It is described in Chapter 10 and later in this chapter.) This substance also helps control the balance of sodium and water. It does this by promoting renal elimination of sodium.

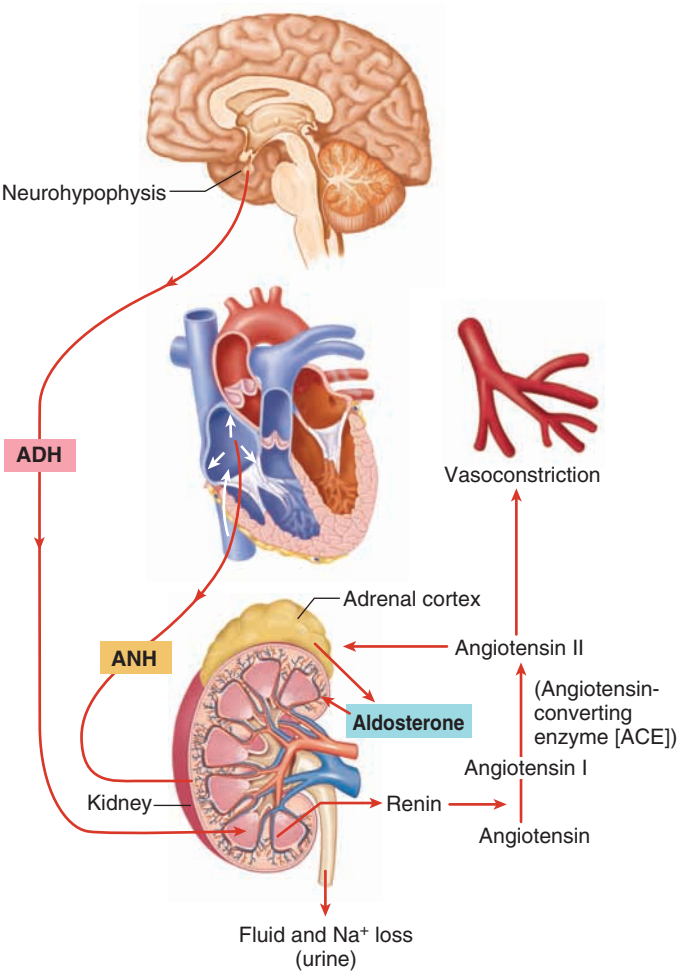

FIGURE 11-8 Three mechanisms that influence total plasma volume. The antidiuretic hormone (ADH) mechanism and renin-angiotensin-aldosterone system (RAAS) tend to increase water retention and thus increase total plasma volume. The atrial natriuretic hormone (ANH) mechanism antagonizes these mechanisms by promoting water loss and thus promoting a decrease in total plasma volume. (From Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

ALTERATIONS IN SODIUM, CHLORIDE, AND WATER BALANCE

In the healthy body, homeostatic mechanisms maintain a constant balance between the intake and excretion of water. The water gained each day basically equals the water lost. The body gains water mainly in two ways: (1) when a person drinks fluids and eats moist foods and (2) when water is formed through the oxidation of hydrogen in food during the metabolic process. The body loses water through the kidneys as urine, through the bowel as feces, through the skin as perspiration, through exhaled air as vapor, and by the excretion of tears and saliva. Two abnormal states of body fluid balance can occur. If the water lost exceeds the water gained, a water deficit occurs. This is **dehydration.** If the water gained exceeds the water lost, a water excess occurs. This is **overhydration.**

DEHYDRATION

Dehydration may be described in three ways. **Isotonic dehydration** is excessive loss of sodium and water in equal amounts. **Hypernatremic dehydration** is the loss of more water than sodium. **Hyponatremic dehydration** is the loss of more sodium than water.

CRITICAL THINKING

Consider the causes of dehydration and your knowledge of anatomy and physiology. What two age groups do you think are at highest risk for dehydration? Why?

Isotonic Dehydration

Possible Causes

Usually severe or long-term vomiting or diarrhea
Systemic infection
Intestinal obstruction

Signs and Symptoms

Dry skin and mucous membranes
Poor skin turgor
Longitudinal wrinkles or furrows of the tongue
Oliguria (decreased urinary output)

Anuria (essentially no urinary output [100 mL or less in 24 hours])
Acute weight loss
Depressed or sunken fontanelles in infants

Treatment

An intravenous infusion of an isotonic solution is administered. The solution has a solute concentration equal to that of blood (0.9% sodium chloride or normal saline typically is used).

Hypernatremic Dehydration

Possible Causes

Excessive use or misuse of diuretics
Continued intake of sodium in the absence of water consumption
Excessive loss of water with little loss of sodium
Profuse, watery diarrhea

Signs and Symptoms

Dry, sticky mucous membranes
Flushed, doughy skin
Intense thirst
Oliguria or anuria
Increased body temperature
Altered mental status

Treatment

Volume replacement is administered. This usually begins with isotonic fluids, because the patient often is both salt and water depleted, with the water supply being more depleted. (Isotonic fluids are relatively hypotonic in these patients.)

Hyponatremic Dehydration

Possible Causes

Use of diuretics
Excessive perspiration (heat-related illness)
Salt-losing renal disorders
Increased water intake (e.g., excessive use of water enemas)

Signs and Symptoms

Abdominal or muscle cramps
Seizures
Rapid, thready pulse
Diaphoresis (profuse sweating)
Cyanosis

Treatment

Intravenous fluid replacement (i.e., normal saline or lactated Ringer's solution) is administered. Occasionally, hypertonic saline is given (e.g., in seizures caused by hyponatremia).

OVERHYDRATION

Because overhydration is an increase in body water, it results in a decrease in the solute concentration. (The total body amount of solute actually may be increased. However, because body water is increased more, the solute concentration is decreased.) This water excess may result from parenteral administration of excessive fluids, impaired cardiac function, impaired renal function, or some endocrine dysfunctions. Signs and symptoms of overhydration may include the following:

- Shortness of breath
- Puffy eyelids
- Edema
- **Polyuria** (voiding of a large volume of urine within a given time)
- Moist crackles (on pulmonary examination)
- Acute weight gain

Treatment for overhydration depends on the cause. Water restriction is the main treatment for excessive water administration. It also is the main treatment for certain endocrine problems. A diuretic may be indicated for patients with cardiac impairment. It also may be the treatment for patients with renal impairment. When profound hyponatremia is associated with overhydration (a low serum sodium level and associated seizures or altered consciousness), administration of saline may be indicated.

SHOW ME THE EVIDENCE

Overhydration

Researchers in California reviewed the records of 545 patients reported to have ecstasy intoxication. Their goal was to determine whether the incidence of hyponatremia differed in males and females. Of the 188 cases with a documented sodium level, 38.8% were hyponatremic. Of the patients with hyponatremia, 75.3% were women and 24.7% men. Females had increased odds of hyponatremia (odds ratio [OR] 4.0; 95% confidence interval [CI] 2.1 to 7.6). Females with hyponatremia had a higher incidence of coma.

From Rosenson J, Smollin C, Sporer K, et al: Patterns of ecstasy-associated hyponatremia in California, *Ann Emerg Med* 49(2):164-171, 2007.

ELECTROLYTE IMBALANCES

In addition to water and sodium imbalances, disturbances may occur in the balance of electrolytes other than sodium. These electrolytes include potassium, calcium, and magnesium (Table 11-2).

Potassium. Potassium is the major positively charged ion in ICF. The body must keep potassium levels within a narrow range. This allows normal function of the nerves, cardiac system, and skeletal muscle. *Obligate* potassium losses are losses that cannot be avoided. These usually are minimal. In addition, they normally can be replenished through the diet. Excess potassium usually is excreted by the kidneys. Potassium plays a key role in muscle contraction, enzyme action, nerve impulse conduction, and cell membrane function. Potassium imbalances interfere with neuromuscular function. They may cause cardiac rhythm disturbances (**dysrhythmias**). These may even include sudden cardiac death.

Hypokalemia is an abnormally *low* level of potassium in the blood. It can be caused by reduced dietary intake (rare), poor potassium absorption, increased gastrointestinal losses from vomiting or diarrhea, renal disease, infusion of solutions low in potassium, or the use of some

TABLE 11-2 Electrolyte Concentrations of Intracellular and Extracellular Fluid

Predominant Cations	Normal Adult Range
Intracellular	
Potassium (K^+)	3.5-5.0 mEq/L
Magnesium (Mg^{++})	1.5-2.0 mEq/L
Extracellular	
Sodium (Na^+)	135-145 mEq/L
Predominant Anions	**Normal Adult Range**
Intracellular	
Phosphate (PO_4^{3-})	50-60 units/L
Extracellular	
Chloride (Cl^-)	90-108 mEq/L
Bicarbonate (HCO_3^-)	22-30 mEq/L

medications (most commonly diuretics, but steroids, theophylline, and others have also been implicated). The most common cause of hypokalemia in the United States is the use of diuretics. About 80% of patients who are receiving diuretics become hypokalemic.[4] Signs and symptoms of hypokalemia may include the following:

- Malaise
- Skeletal muscle weakness
- Cardiac dysrhythmias
- Decreased reflexes
- Weak pulse
- Faint or distant heart sounds
- Shallow respiration
- Low blood pressure
- Anorexia
- Vomiting
- Gaseous distention
- Excessive thirst (rare)

In-hospital treatment of hypokalemia involves intravenous or oral administration of potassium.

CRITICAL THINKING

What common illness mimics many of the signs and symptoms of fluid and electrolyte imbalance?

Hyperkalemia is an abnormally *high* level of potassium in the blood. This condition may be caused by acute or chronic renal failure, burns, crush injuries, severe infections or other conditions in which large amounts of potassium are released, excessive use of potassium salts, and a shift of potassium from the cells into the extracellular fluid (such as occurs in acidosis, described later in this chapter). Signs and symptoms of hyperkalemia may include the following:

- Cardiac conduction disturbances
- Irritability
- Abdominal distention
- Nausea
- Diarrhea
- Oliguria
- Weakness (an early sign) and paralysis (a late sign of severe hyperkalemia)

In-hospital treatment for hyperkalemia involves restriction of potassium. It also involves administration of a cation exchange resin, either orally or through a nasogastric tube. For severe potassium level elevation, **hemodialysis** may be indicated. In an emergency, administration of ***calcium*** intravenously can be lifesaving. This is especially true with cardiac dysrhythmias, which are life-threatening. Other critical efforts include intravenous administration of glucose and ***insulin.*** This helps to lower the serum potassium level. It forces potassium movement intracellularly along with the glucose. ***Sodium bicarbonate*** also causes potassium to move back into the cells. High-dose nebulized ***albuterol*** may also be administered to lower potassium levels. ***Albuterol*** does this by stimulating the release of insulin, which in turn stimulates the sodium-potassium pump, causing potassium to be shifted into the cells.[5]

Calcium. Calcium is a **bivalent cation** (an ion with two positive charges). It is essential for a variety of body functions. These include neuromuscular transmission, cell membrane permeability, hormone secretion, growth and ossification of bones, and muscle contraction (including smooth, cardiac, and skeletal muscle). Calcium intake in a balanced diet usually is sufficient for normal body needs. Calcium is excreted through urine, feces, and perspiration.

Hypocalcemia is an abnormally low level of calcium in the blood. It may result from endocrine dysfunction (mostly underactivity of the parathyroid gland). It may also result from renal insufficiency; a decreased intake or malabsorption of calcium; or **toxic shock syndrome.** Another cause of hypocalcemia is a deficiency of, malabsorption of, or inability to activate vitamin D (which is responsible for calcium absorption). Signs and symptoms of hypocalcemia may include the following:

- **Paresthesia** (numbness or tingling sensation)
- **Tetany** (muscle twitching)
- Abdominal cramps
- Muscle cramps
- Neural excitability
- Personality changes
- Abnormal behavior
- Convulsions
- Heart failure

In-hospital treatment for hypocalcemia involves intravenous administration of calcium ions. Calcium salt and vitamin D may be given orally for maintenance.

Hypercalcemia is an abnormally high level of calcium in the blood. It may be caused by various tumors. Other common causes include parathyroid overactivity, thyroid

dysfunction, diuretic therapy, some cancers, and excessive administration of vitamin D (as in the treatment of *osteoporosis*). Calcium can be deposited in various body tissues, including many organ systems. Examples include the gastrointestinal system, central nervous system, renal system, neuromuscular system, and cardiovascular system. Signs and symptoms of hypercalcemia include the following:

- **Hypotonicity of the muscles** (decreased muscle tone or tension)
- Renal stones
- Altered mental status, seizures, coma
- Deep bone pain
- Cardiac dysrhythmias

The treatment of hypercalcemia is aimed at controlling the underlying disease. It may include hydration and/or drug therapy to decrease the calcium level. In-hospital therapy for severe hypercalcemia may include forced diuresis with normal saline and ***furosemide*.** The patient also may be given calcium-lowering drugs. Examples of these are thyrocalcitonin, steroids (glucocorticoids), and plicamycin (a cytotoxic drug that inhibits bone reabsorption of calcium). Hemodialysis may be needed in patients with heart failure or renal insufficiency.

NOTE

Changes in the level of phosphate in the blood also can occur. This can result in hypophosphatemia or hyperphosphatemia. **Hypophosphatemia,** an abnormally low serum phosphate level, may be caused by intestinal malabsorption or increased excretion of phosphate by the kidneys. **Hyperphosphatemia,** an abnormally high serum phosphate level, is associated with acute or chronic renal failure or diminished activity of the parathyroid gland.

Magnesium. Like calcium, magnesium is a bivalent cation. It activates many enzymes. Magnesium is distributed throughout the body approximately as follows: 50% in an insoluble state in bone; 45% as an intracellular cation; and 5% in extracellular solution. Magnesium is excreted by the kidneys. Its physiological effects on the nervous system resemble those of calcium.

Hypomagnesemia is an abnormally low level of magnesium in the blood. It may be encountered in conditions involving alcoholism, diabetes, malabsorption disorders, starvation, diarrhea, diuresis, and diseases that cause hypocalcemia and hypokalemia. The condition is characterized by increased irritability of the central nervous system. Signs and symptoms of hypomagnesemia include the following:

- Tremors
- Nausea or vomiting
- Diarrhea
- Hyperactive deep reflexes
- Confusion (including hallucinations)
- Seizures or myoclonus (muscle spasms)
- Cardiac dysrhythmias (which may lead to cardiac arrest)

Treatment for significant, symptomatic hypomagnesemia involves intravenous administration of a solution that contains magnesium. Magnesium sulfate would be given to treat **torsades de pointes** associated with hypomagnesemia. (Torsades de pointes is a type of ventricular dysrhythmia, described in Chapter 22.)

Hypermagnesemia is an abnormally high level of magnesium in the blood. It occurs mainly in patients with chronic renal insufficiency. It also can occur in patients who take large amounts of magnesium-containing compounds. Examples of such compounds are **cathartics** (e.g., magnesium citrate, magnesium sulfate) and antacids (e.g., magnesium hydroxide). Hypermagnesemia causes central nervous system depression, profound muscular weakness, and **areflexia** (absence of reflexes). It also causes cardiac rhythm disturbances, which may lead to sudden death. Signs and symptoms of hypermagnesemia include the following:

- Sedation
- Confusion
- Muscle weakness
- Respiratory paralysis

The most effective treatment for hypermagnesemia is hemodialysis. It can return blood levels to normal in about 4 hours. Calcium salts may be given parenterally as well. These act as an antagonist to magnesium. Administration of intravenous glucose and ***insulin*** also drives magnesium back into the cells. This treatment can be used in emergencies when respiratory depression or cardiac conduction defects are present.

Acid-Base Balance

Acids are produced by the body through normal metabolism. Two types of acids are produced: *respiratory acids* (culminating in carbon dioxide [CO_2]) and *nonrespiratory (metabolic) acids*. **Bases** are used in metabolic disturbances to return the body's plasma to normal pH. For physiological functioning, the balance between acids and bases must be kept in a narrow range. The body's main regulators of **acid-base balance** are the lungs and the kidneys. The lungs secrete respiratory acids. The kidneys secrete metabolic acids.

pH

Hydrogen ions are protons with a positive charge. In chemistry, a hydrogen ion that loses its charge is marked with a positive sign (H^+). Likewise, a hydrogen ion that gains a charge is marked with a negative sign (H^-). *Acids* are materials that release or donate hydrogen ions. *Bases* (alkaline substances) receive, or absorb, hydrogen ions. Thus they neutralize positively charged ions. The concentration of hydrogen ions is expressed as the **pH.** This indicates the *potential for hydrogen*. A small change in pH is very important: *The strength of an acid or a base changes by 10 times with **each** unit change of pH*. For example, a pH that changes by 0.3 unit (e.g., from 7.4 to 7.1) doubles the concentration of hydrogen ions (Box 11-3). The pH is neutral (6.8 to 7) when equal numbers of positive and negative ions are present. A solution increases in acidity as the pH

BOX 11-3 pH Values

A solution of pH 1 is 1 million times as acidic as a solution of pH 7.
pH 2 is 100,000 times as acidic as pH 7.
pH 3 is 10,000 times as acidic as pH 7.
pH 4 is 1000 times as acidic as pH 7.
pH 5 is 100 times as acidic as pH 7.
pH 6 is 10 times as acidic as pH 7.
pH 7 is neutral (distilled water).
pH 8 is $\frac{1}{10}$ as acidic as pH 7, or 10 times as alkaline.
pH 9 is $\frac{1}{100}$ as acidic as pH 7, or 100 times as alkaline.

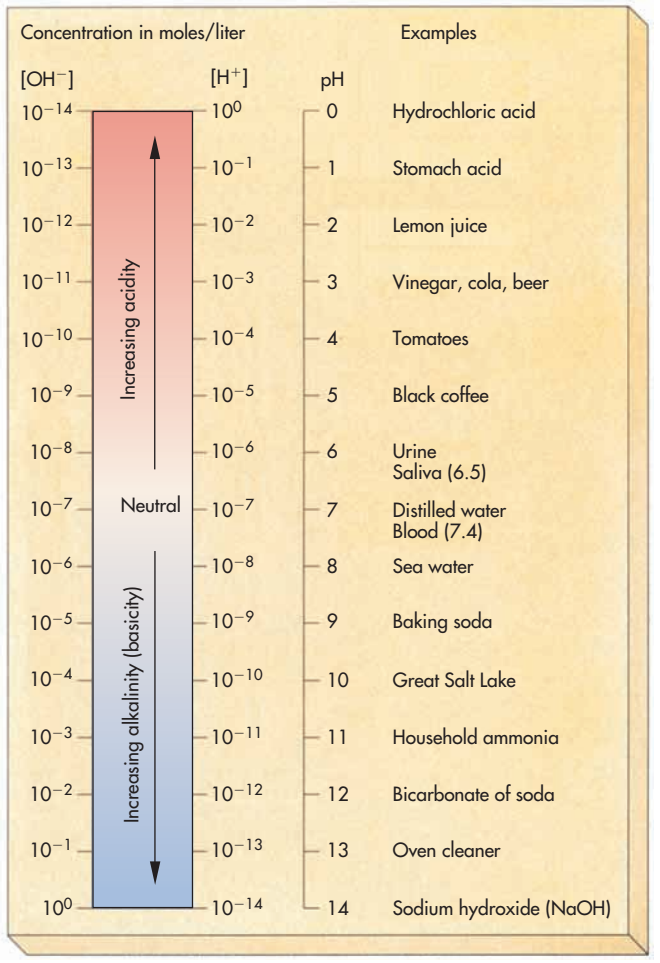

FIGURE 11-9 The pH scale. A pH of 7 is considered neutral. Values less than 7 are acidic (the lower the number, the more acidic the substance). Values greater than 7 are basic (the higher the number, the more basic the substance). Representative fluids and their approximate pH values are listed.

decreases. It increases in alkalinity (basicity) as the pH rises (Figure 11-9).

BUFFER SYSTEMS

The healthy body is sensitive to changes in the concentration of hydrogen ions. In fact, it tries to maintain the pH of extracellular fluid at 7.4. This is carried out through three related compensatory mechanisms. These are *carbonic acid–bicarbonate buffering, protein buffering,* and *renal buffering.* These mechanisms are stimulated by changes in the pH. They require normal organ function to be effective in maintaining acid-base balance.

Carbonic Acid–Bicarbonate Buffering. Bicarbonate, carbon dioxide, and carbonic acid are always present in a dynamic balance in the blood. **Bicarbonate** (HCO_3^-) arises from the transport of carbon dioxide in the blood. Under the influence of the enzyme **carbonic anhydrase** (found in the alveoli, walls of the lungs, and epithelial cells in the renal tubules), carbon dioxide dissolves in the water of blood. It reacts with water in red blood cells to form **carbonic acid** (H_2CO_3). Carbonic acid dissociates into hydrogen and bicarbonate ions. Because of the effects of carbonic acid or sodium bicarbonate, the buffering must occur through the lungs or kidneys. This means that the pH can be increased or decreased in one of three ways: (1) by the renal system that excretes or retains sodium bicarbonate; (2) by the respiratory system that excretes or retains carbonic acid, or its component carbon dioxide; or (3) by both systems acting together. At a physiological pH of 7.4, the normal ratio of carbonic acid to bicarbonate is 1:20 (1 part of carbonic acid to every 20 parts of sodium bicarbonate), and is summarized by the chemical equation:

$$CO_2 + H_2O \rightleftarrows H_2CO_3 \rightleftarrows H^+ + HCO_3^-$$

Bicarbonate may bind with a cation to form base bicarbonate (e.g., $NaHCO_3$). The ratio of carbonic acid to base bicarbonate determines the pH. As long as there is 1 *milliequivalent* (mEq) of carbonic acid for each 20 mEq of base bicarbonate in the extracellular fluid, the pH stays within normal limits.

NOTE
A milliequivalent (see Chapter 14) is the number of grams of solute dissolved in 1 mL of a normal solution.

The carbonic acid–bicarbonate compensatory mechanism is triggered immediately by changes in pH. The respiratory rate helps maintain this balance (Figure 11-10). This is the most important buffering system in extracellular fluid. It can buffer up to 90% of the hydrogen ions in extracellular fluid and has little effect on the cells.[6]

Protein Buffering. Both intracellular and extracellular proteins have negative charges. Both also can serve as buffers for changes in the pH. However, most proteins are inside cells. Protein buffering, therefore, is mainly an intracellular buffer system. **Hemoglobin** (Hb) is an excellent intracellular buffer, because it can bind with hydrogen ions (forming a weak acid) and carbon dioxide.

After oxygen is released in the peripheral tissues, hemoglobin binds with carbon dioxide and hydrogen ions. As the blood reaches the lungs, these actions are reversed.

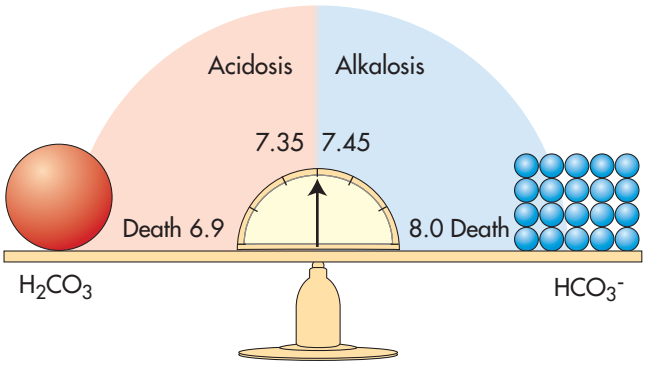

FIGURE 11-10 Bicarbonate buffer system. When body fluids are in acid-base balance, the ratio of bicarbonate (HCO_3^-) to carbonic acid (H_2CO_3) normally is 20:1, and the pH is between 7.35 and 7.45.

Hemoglobin binds with oxygen, releasing carbon dioxide and hydrogen ions. The released hydrogen ions combine with bicarbonate ions, forming carbonic acid. The carbonic acid dissociates into carbon dioxide and water. Then the lungs exhale the carbon dioxide. Therefore in normal circumstances, respirations help maintain pH. The respiratory centers are more responsive to pH changes than to changes in the oxygen level of the tissues. For this reason, the amount of carbon dioxide in the blood (and hence the pH), rather than the need for oxygen in the tissues, controls the rate of breathing in healthy individuals. Within minutes of a decrease in the pH, alveolar ventilation increases in an effort to lower the carbon dioxide concentration.

Renal Buffering. The kidneys help maintain an acid-base balance through three mechanisms. One is the recovery of bicarbonate, which is filtered into the tubules. Another is the excretion of hydrogen ions against a gradient to acidify the urine. The third is the excretion of **ammonium ions** (NH_4), each of which carries a hydrogen ion with it. The renal system compensates for acid-base imbalances slowly compared with the protein and bicarbonate buffer systems. The kidneys can take several hours to days to restore the pH to the normal physiological range.

NOTE
The concentration of carbonic acid is controlled by the lungs. (Carbonic acid is dissolved carbon dioxide.) The concentration of bicarbonate is controlled by the kidneys.

ACID-BASE IMBALANCE

As stated previously, acid-base balance is maintained mainly through two factors: a respiratory element and a metabolic element. Any condition that increases the concentration of carbonic acid or decreases the concentration of base bicarbonate causes **acidosis.** Any condition that increases the concentration of base bicarbonate or decreases the concentration of carbonic acid causes **alkalosis.** In discussing acid-base imbalance, it is important to remember that acidosis makes the pH *more* acidic than normal. Alkalosis makes the pH *less* acidic than normal (Box 11-4). Also, a patient can have both disorders at the same time (e.g., respiratory acidosis and metabolic alkalosis, described later). When two disturbances are present, one usually dominates. The other attempts to compensate.

BOX 11-4 Typical Acid-Base Measurements

Normal arterial pH range: 7.35-7.45 (7.40)
Normal arterial P_{CO_2} range: 35-46 mm Hg (40 mm Hg)
Normal serum CO_2 concentration range*:
22-26 mEq/L (24 mEq/L)

Acidosis	Alkalosis
pH <7.35	pH >7.45
HCO_3^- concentration <24 mEq/L	HCO_3^- concentration >24 mEq/L
P_{CO_2} >40 mm Hg	P_{CO_2} <40 mm Hg

*Represents lab value of HCO_3^- concentration.

ACIDOSIS

The accumulation of acid and the resulting acidosis (pH below 7.35) cause the pH to be more acidic compared to the normal pH of 7.4. (A decrease in pH means an increase in acidity.) A discussion of respiratory and metabolic acidosis follows.

Respiratory Acidosis. Respiratory acidosis is caused by the retention of carbon dioxide. This leads to an increase in the partial pressure of carbon dioxide (P_{CO_2}). This state usually is caused by an imbalance in the production of carbon dioxide and its elimination through alveolar ventilation (Figure 11-11). Respiratory acidosis can be summarized by the following chemical equation:

$$\downarrow \text{Respiration} = \uparrow CO_2 + H_2O \rightarrow \uparrow H_2CO_3 \rightarrow \uparrow H^+ + HCO_3^-$$

Reductions in alveolar ventilation may occur as a result of the following:

- Respiratory depression
- Respiratory arrest
- Cardiac arrest
- Neuromuscular impairment
- Medications (e.g., sedatives, hypnotics)
- Chest wall injury (e.g., flail chest, pneumothorax)
- Pulmonary disorders (e.g., airway obstruction, chronic obstructive pulmonary disease, pulmonary edema)

NOTE
In respiratory acidosis, the primary abnormality is failure of the lungs to excrete carbon dioxide efficiently.

When the respiratory system cannot continue as a compensatory mechanism to correct the acidosis, the body's renal system must conserve bicarbonate and excrete more

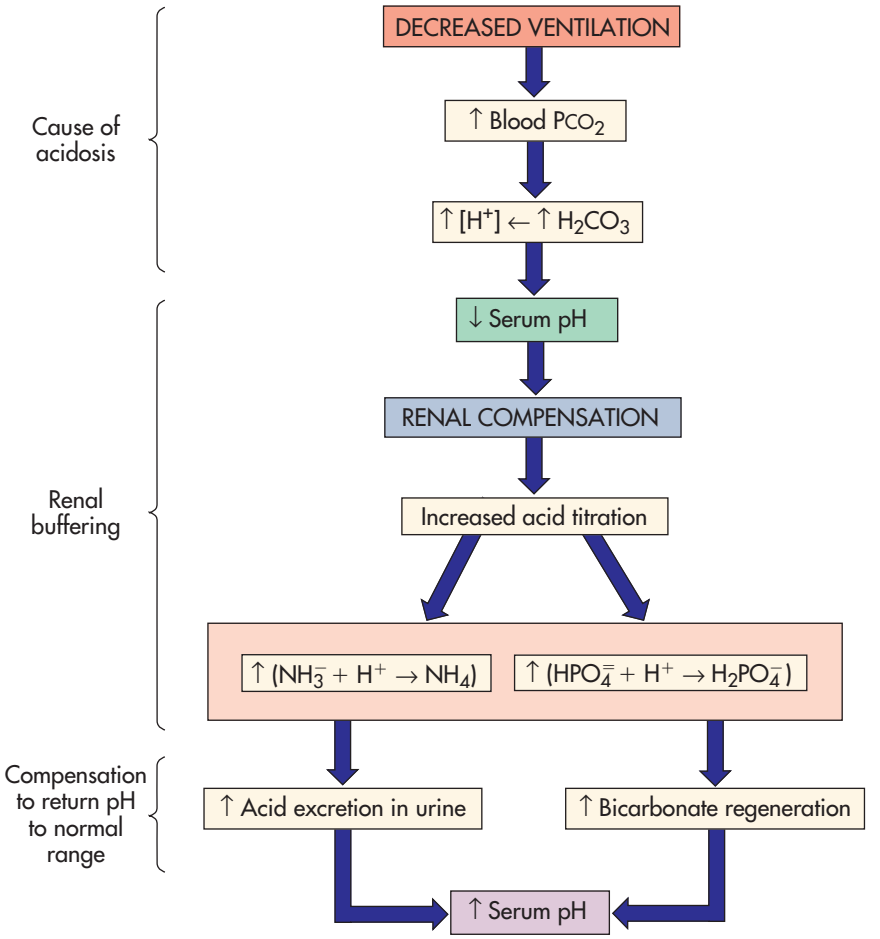

FIGURE 11-11 Respiratory acidosis. An excess of carbon dioxide in the body results in acidosis.

hydrogen ions to help bring the pH into normal limits. The kidneys take some time to restore pH. Thus the patient in respiratory acidosis should be treated by improving ventilation to quickly eliminate carbon dioxide. This may be done by assisting ventilations to decrease the P_{CO_2}. Supplemental oxygen also should be given to help correct any accompanying **hypoxemia** (which itself can lead to acidosis).

CRITICAL THINKING

What kind of acid-base imbalance exists in a patient you have just defibrillated and resuscitated from cardiac arrest? How are you going to treat that imbalance?

Metabolic Acidosis. Metabolic acidosis results from a buildup of acid or a loss of base. When excessive acid is produced by the body, the acid spills into the extracellular fluid. This, in turn, consumes some bicarbonate buffers. The result is an increase in acid and a decrease in available base (Figure 11-12). Metabolic acidosis can be summarized by the following equation:

$$\uparrow H^+ + HCO_3^- \rightarrow \uparrow H_2CO_3 \rightarrow H_2O + \uparrow CO_2$$

The increase in available hydrogen ions forces the reaction to the right. This decreases the amount of base bicarbonate.

NOTE

Metabolic acidosis occurs when the amount of acid generated by the body exceeds the body's buffering capacity.

The healthy respiratory system instantly tries to compensate for the acidosis. It does this by increasing the rate and depth of breathing to reduce carbon dioxide levels. As the carbon dioxide concentration falls, so does the concentration of carbonic acid. This moves the pH toward normal. In addition, the kidneys excrete more hydrogen ion to equilibrate the excess acid in the extracellular fluid.

The four most common forms of metabolic acidosis encountered in the prehospital setting are lactic acidosis, diabetic ketoacidosis, acidosis caused by renal failure, and acidosis caused by ingestion of toxins (poisons).

Lactic Acidosis. Lactic acid is made when a large number of cells are inadequately perfused. This results in

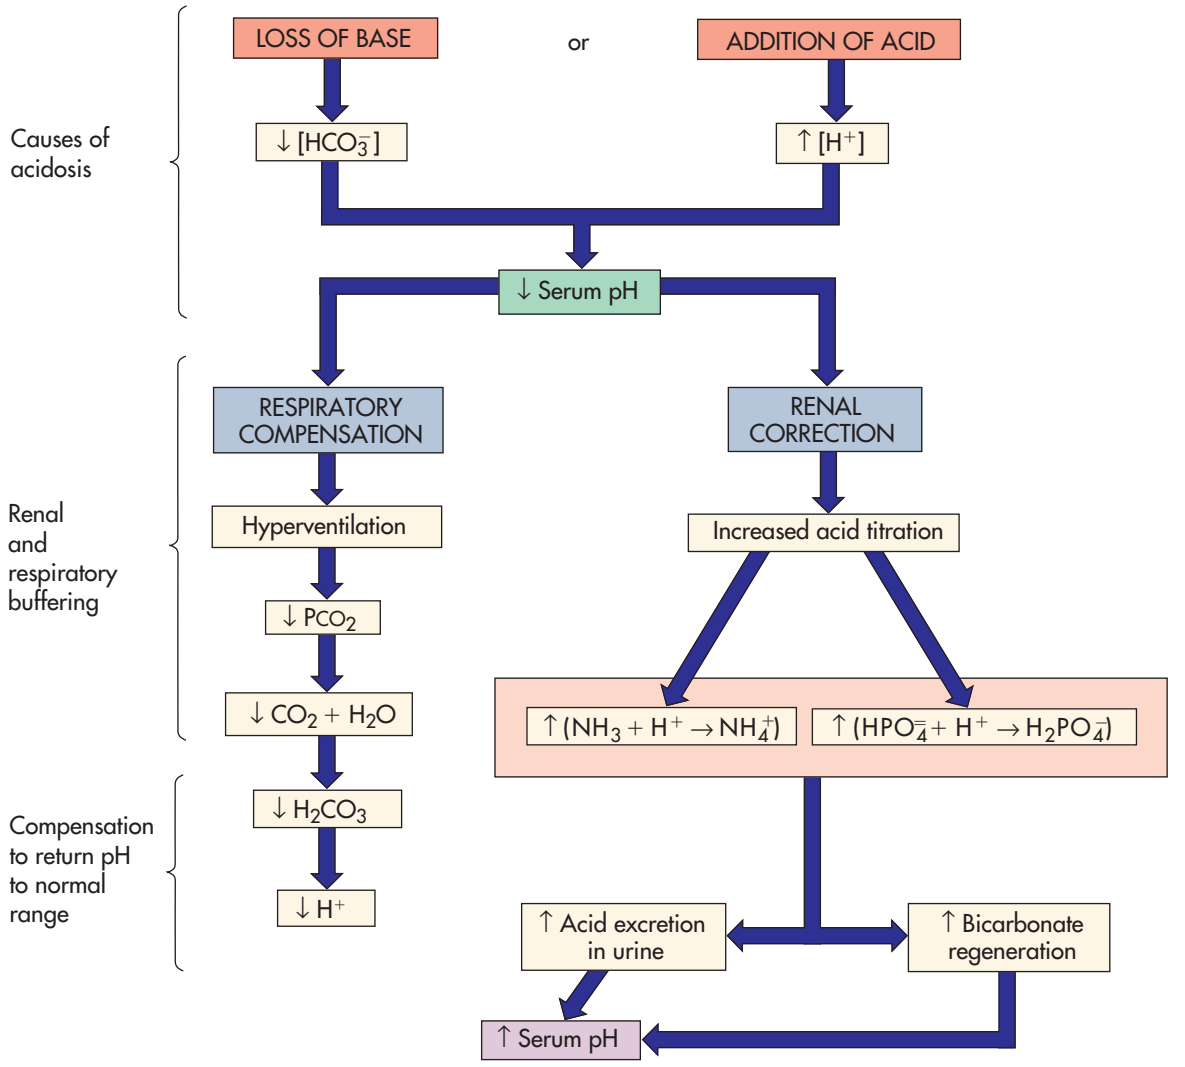

FIGURE 11-12 Metabolic acidosis. With an excess of metabolic acids, bicarbonate is consumed and hydrogen ions are liberated, resulting in acidosis. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

a shift from **aerobic** (with oxygen) to **anaerobic** (without oxygen) metabolism. The end product of anaerobic metabolism is lactic acid. The lactic acid releases hydrogen ions and becomes **lactate.** This creates systemic acidosis. Normally, the liver changes lactate back into glucose, or lactate is oxidized to carbon dioxide and water. When lactic acid is produced faster than it is metabolized, **lactic acidosis** occurs. The most common causes of systemic lactic acidosis are extreme exertional states (e.g., seizures), **ischemia** (reduced blood supply) in large muscles or organs (e.g., *mesenteric ischemia*), circulatory failure, and shock. Specific complications associated with lactic acidosis are thought to include the following:

- Decreased force of cardiac contraction
- Decreased peripheral response to catecholamines
- Hypotension and shock
- Cardiac muscle that is refractory to defibrillation

CRITICAL THINKING

Think about the last time you ran so fast you had a muscle cramp. What acid-base changes were occurring inside your body? How did your body compensate for those changes?

Treatment of lactic acidosis involves reestablishing tissue perfusion and cardiac output. This allows the liver to regenerate bicarbonate by metabolizing lactate to carbon dioxide and water. Hyperventilation is sometimes advised to induce **respiratory alkalosis** in these cases. Vigorous rehydration to support circulation, and perhaps intravenous administration of ***sodium bicarbonate*** for immediate compensation (if the patient is in cardiac arrest), may also be indicated. Correction of lactic acidosis often depends on identification and rectification of the underlying cause.

Diabetic Ketoacidosis. Ketoacidosis usually is a complication of **diabetes mellitus.** It also may be seen in

alcoholics (*alcoholic ketoacidosis*). Diabetic ketoacidosis usually results when a patient fails to take adequate ***insulin.*** It also may develop when the need for insulin increases. This may occur, for example, in cases of infection or trauma. Insulin is required for many cells to absorb glucose. With impaired glucose utilization, fatty acids are metabolized, producing **ketone bodies** and releasing hydrogen ions. Large amounts of ketone bodies exceed the ability of the body's buffering system to compensate. This results in acidosis and a decrease in blood pH. Prehospital care for patients with diabetic ketoacidosis involves administration of normal saline for volume repletion. (The pathophysiology of diabetes is further addressed in Chapter 26).

Acidosis Caused by Renal Failure. The kidneys help maintain acid-base balance. They do this by reabsorbing or secreting either bicarbonate or hydrogen ions as needed. This keeps the pH constant. Renal failure affects the compensatory mechanisms of the kidneys to varying degrees. Patients with moderate to severe renal failure often have mild to moderate acidosis. Acidosis results because the failing kidneys are unable to excrete the acid waste products efficiently. These waste products are the result of normal metabolic processes.

Acidosis Caused by Ingestion of Toxins. Ingestion of some toxins can cause metabolic acidosis. Examples of such toxins are ethylene glycol, methanol, and salicylate, a component of ***aspirin.*** These and other toxins lead to the production of toxic metabolites. They may result in acid-base disorders. These disorders are characterized by metabolic acidosis and compensatory respiratory alkalosis. Treatment for various toxic ingestions frequently includes gastrointestinal evacuation but also may require hemodialysis, diuresis, hydration to promote excretion, and specific antagonistic or antidotal therapy.

NOTE
In a patient with renal failure, administration of intravenous (IV) fluids may rapidly lead to overhydration.

ALKALOSIS

Alkalosis (pH above 7.45) causes the blood and body fluids to be less acidic compared to the normal pH of 7.4. (An increase in pH means a decrease in acidity.)

Respiratory Alkalosis. Hyperventilation may produce respiratory alkalosis by decreasing the P_{CO_2} (Figure 11-13).

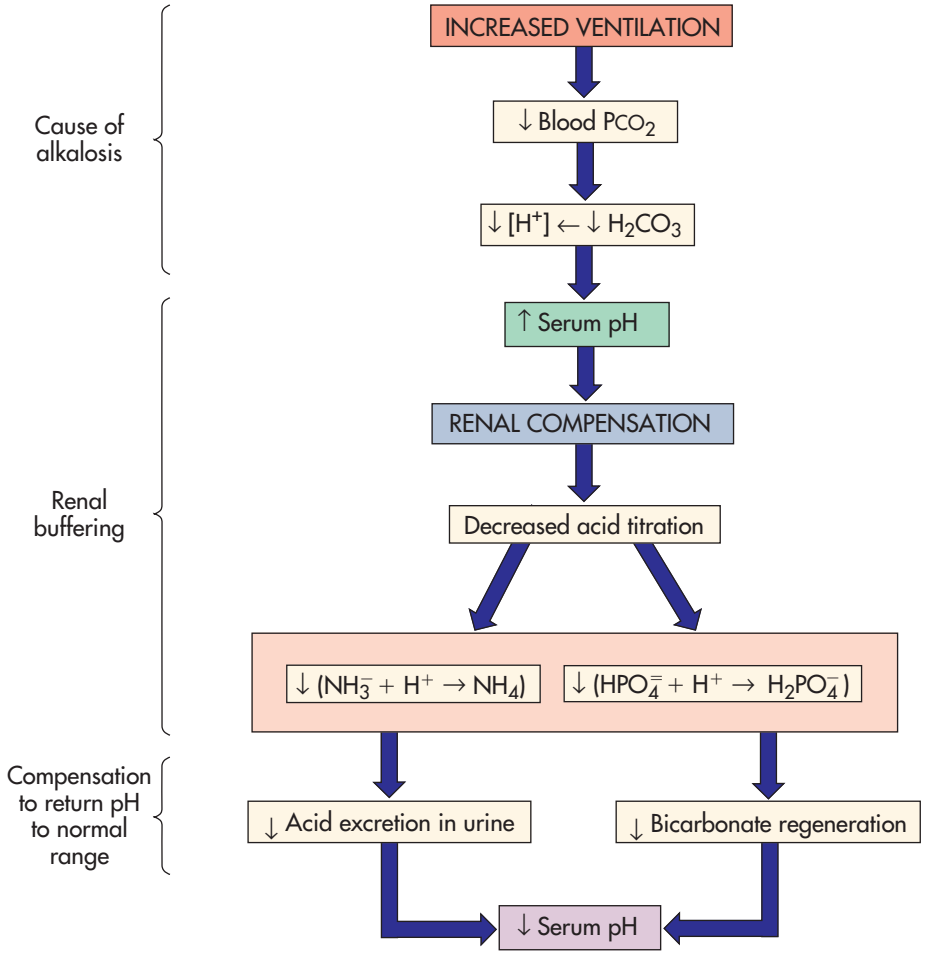

FIGURE 11-13 Respiratory alkalosis. A deficit of carbon dioxide results in respiratory alkalosis.

Hyperventilation is common in patients who are acutely ill. It is often seen in the early stages of *sepsis, peritonitis, shock,* and *respiratory ailments*. Respiratory alkalosis can be summarized by the following chemical equation:

$$\uparrow \text{Respiration} = \downarrow CO_2 + H_2O \rightarrow \downarrow H_2CO_3 \rightarrow \downarrow H^+ + HCO_3^-$$

NOTE

Respiratory alkalosis is caused by hyperventilation. This lowers the partial pressure of carbon dioxide (P_{CO_2}) in the alveoli (the air cells in the lungs) and subsequently the P_{CO_2} in the blood.

When carbonic acid is lacking because of excessive elimination of carbon dioxide, the blood pH rises. Thus the kidneys must excrete bicarbonate ions and retain hydrogen ions. They do this in an effort to return the pH to normal. Treatment of respiratory alkalosis is directed at correcting the underlying cause of the hyperventilation. An initial approach is to administer low-concentration oxygen to the patient. Another is to provide calming measures to assist the patient with slow, controlled breathing.

Metabolic Alkalosis. Metabolic alkalosis (rare) most often results from loss of hydrogen ions (primarily from the stomach), ingestion of large amounts of absorbable base sodium bicarbonate (baking soda) or calcium carbonate (Tums, other antacids), or excessive intravenous administration of alkali (e.g., intravenous injection of ***sodium bicarbonate***). The use of diuretics also may be a factor (Figure 11-14). Metabolic alkalosis can be summarized by the following chemical equation:

$$\downarrow H^+ + HCO_3^- \rightarrow \downarrow H_2CO_3^- \rightarrow H_2O + \downarrow CO_2$$

The loss of hydrogen ions is the initial cause of metabolic alkalosis. This may result from vomiting (loss of hydrochloric acid), suctioning of gastric contents, or increased renal excretion of hydrogen ions in the urine. When vomiting occurs, gastric acid (i.e., hydrochloric acid) is lost, but volume also is depleted.

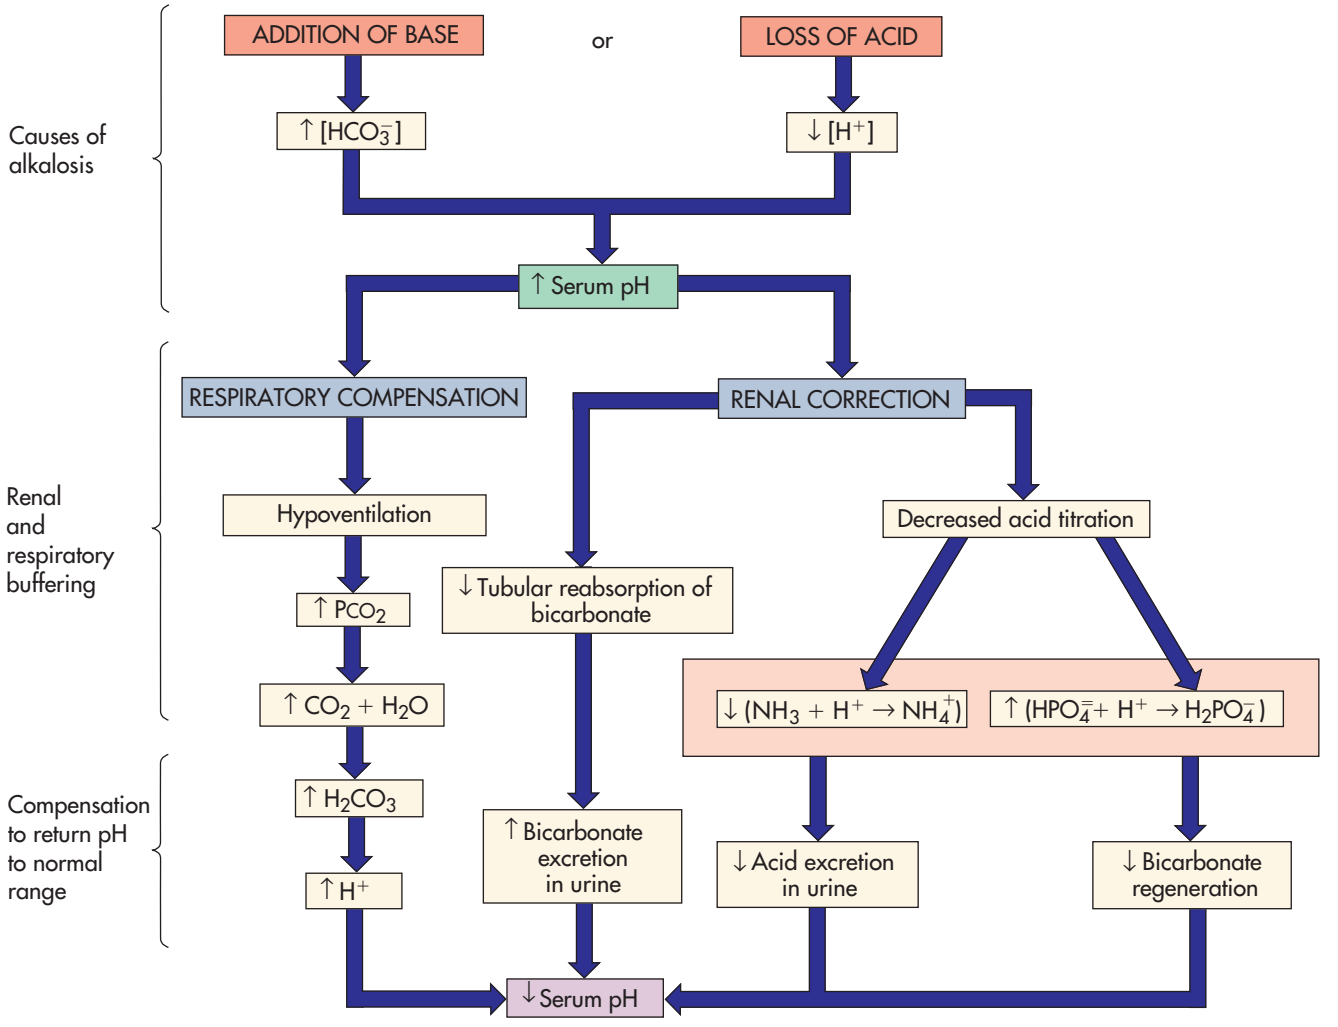

FIGURE 11-14 Metabolic alkalosis. An excess of bicarbonate results in metabolic alkalosis. (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 5, St Louis, 2005, Mosby.)

Chronic use of diuretics can result in volume depletion. The loss of sodium chloride and potassium causes a relative increase in bicarbonate concentration. (The kidneys defend against volume depletion. They increase reabsorption of sodium and thus water.) When sodium is reabsorbed, either potassium or hydrogen ions must be excreted. This action helps to maintain electrical neutrality. The excretion of hydrogen ions can lead to a net increase in bicarbonate level. This, in turn, can lead to metabolic alkalosis.

At first, the respiratory system tries to compensate. It does so by retaining carbon dioxide. However, this mechanism is limited by the development of hypoxemia. (Hypoventilation causes a rise in the P_{CO_2} and a decrease in the partial pressure of oxygen [P_{O_2}]. This, in turn, stimulates respiration).

Treatment of metabolic alkalosis is aimed at correcting the underlying condition. Volume depletion, if present, should be corrected. This should be done with isotonic solutions. Hypokalemia may require correction with potassium replacement.

MIXED ACID-BASE DISTURBANCES

Many conditions may cause mixed abnormalities of acid-base regulation. These conditions include various forms of shock. In patients in shock, simultaneous respiratory and metabolic alterations are commonly seen. These develop because pathophysiological changes occur in both the respiratory and the metabolic components of the acid-base system (Box 11-5; also see Table 11-3). Examples of mixed acid-base disturbances include the following:

- Combined respiratory and metabolic acidosis
- Metabolic acidosis and respiratory alkalosis
- Respiratory acidosis and metabolic alkalosis
- Combined respiratory and metabolic alkalosis

Acid-base balance can be a difficult concept to master. In providing emergency care, the paramedic should remember the following primary points:

1. Acid-base balance has two components: a respiratory (CO_2) factor and a nonrespiratory (metabolic) factor.
2. Respiratory acidosis is caused by an increase in the CO_2 level of the blood and body fluids as a result of inadequate breathing. The treatment of respiratory acidosis involves improving ventilation to lower the CO_2 level. Respiratory alkalosis results from hyperventilation.
3. Metabolic acidosis is caused by anaerobic metabolism and lactic acidosis. The treatment of metabolic acidosis involves neutralizing the acid by reestablishing tissue perfusion and cardiac output. Metabolic alkalosis is rare.
4. A patient may have two acid-base disturbances at the same time. One usually dominates, and the other attempts to compensate.
5. The patient's pH is always a product of both respiratory and metabolic components. Neutral pH is 6.8 to 7. The normal pH of blood is 7.4. A decrease in pH indicates an increase in acidity (more acid than normal); an increase in pH indicates a decrease in acidity (less acid than normal).

BOX 11-5 Acid-Base Determination and Other Laboratory Studies

Blood Gas Analysis

Blood gas values are measured for two reasons. One reason is to determine whether the patient is well oxygenated. The second reason is to determine the patient's acid-base status. Most often, blood gas values are measured in a sample of arterial blood obtained in a heparinized syringe (see Appendix A: Advanced Practice Procedures for Critical Care Paramedics). Arterial samples are used for this test more often than venous samples for a good reason. Arterial samples give more direct information about the lungs' ability to oxygenate blood and remove carbon dioxide.

Acid-Base Determination

The patient's acid-base status is assessed by measuring the partial pressure of carbon dioxide (P_{CO_2}) and the hydrogen ion concentration (pH) of the arterial blood. The pH level indicates whether an acid or a base state is present. The P_{CO_2} value indicates whether a respiratory component is a factor in the acidosis or alkalosis. (For instance, it may show whether alveolar hypoventilation or hyperventilation is present.) Table 11-3 summarizes the abnormalities that occur in mixed acid-base disturbances.

Currently, paramedics are not expected to determine the pH by blood gas analysis in the prehospital setting. Pulse oximetry allows continual assessment of the arterial oxygen saturation without invasive procedures. (Under normal circumstances, a saturation of 90% correlates with a partial pressure of oxygen [P_{O_2}] in arterial blood of 60 mm Hg.)

TABLE 11-3 Simple Acid-Base Disturbances

Acid Base Disturbance	Initial Chemical Change	Compensatory Response	pH
Respiratory acidosis	$\uparrow P_{CO_2}$	$\uparrow HCO_3^-$	↓
Respiratory alkalosis	$\downarrow P_{CO_2}$	$\downarrow HCO_3^-$	↑
Metabolic acidosis	$\downarrow HCO_3^-$	$\downarrow P_{CO_2}$	↓
Metabolic alkalosis	$\uparrow HCO_3^-$	$\uparrow P_{CO_2}$	↑

SECTION TWO
Cellular Injury and Disease

ALTERATIONS IN CELLS AND TISSUES

Certain concepts are crucial to an understanding of the disease process. One of these concepts is the way that cells and tissues react to injury, both structurally and

functionally. Changes in the structure and function of cells and tissues can result from cellular adaptation, injury, neoplasia (actual formation of a tumor), aging, and death.

Cellular Adaptation

Cells adapt to their environment (Figure 11-15). They do so to escape and to protect themselves from injury. (An adapted cell is neither normal nor injured.) Adaptations are common. They are a central part of the response to changes in the physiological condition. In many instances the adaptation allows the cell to function more efficiently. For this reason, it can be difficult to distinguish between a pathological response and an extreme adaptation to changing conditions. The following is a list of the five most significant adaptive changes in cells:

1. Atrophy (a decrease in cell size)
2. Hypertrophy (an increase in cell size)
3. Hyperplasia (an excessive increase in the number of cells)
4. Metaplasia (a change from one cell type to another that is better able to tolerate adverse conditions; a conversion into a form that is not normal for that cell)
5. Dysplasia (abnormal changes in mature cells)

Atrophy is a decrease in cellular size that adversely affects cell function. It can affect any organ. However, it is seen most often in skeletal muscle, the heart, the secondary sex organs, and the brain. Causes include decreased use, chronic inflammation, poor nutrition or starvation, inadequate hormonal or nervous stimulation, and reduced blood supply. An example of atrophy is a skeletal muscle that is reduced in size because of prolonged wearing of a cast. Atrophy may be reversed (in some cases) when normal function is restored.

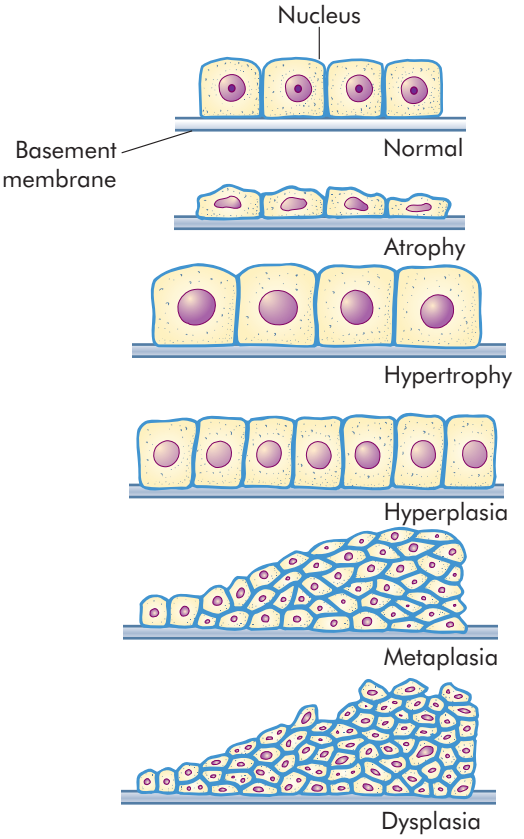

FIGURE 11-15 Adaptive changes in cells. (From Huether SE, McCance KL: *Understanding pathophysiology,* ed 4, St Louis, 2008, Mosby.)

Hypertrophy is an increase in the size of cells. (This occurs without an increase in the number of that type of cell.) Along with the increase in the size of the cells comes an increase in the size of the affected organ. Hypertrophy results when cells are required to do more work to achieve a task. Examples of "normal" or physiological hypertrophy are a weight lifter's large muscles, increased growth of the uterus during pregnancy, and the development of sexual organs in adolescence (initiated by sex hormones). Examples of pathological hypertrophy are enlargement of the heart (myocardial hypertrophy) and of the kidneys (which also can be physiological).

CRITICAL THINKING

What happens to muscle strength when the muscle cells are affected by each of these conditions: atrophy, hypertrophy, and hyperplasia?

Hyperplasia is an excessive increase in the number of cells. This results in an increase in the size of a tissue or an organ. Hyperplasia occurs in response to increased demand. It may be a pathological event. It also may be a normal adaptive mechanism that allows certain organs to regenerate (*compensatory hyperplasia*). The formation of a callus is an example of compensatory hyperplasia. Another example is the increased formation of red blood cells that occurs at high altitudes. An example of pathological hyperplasia is *endometrial hyperplasia*. This condition can cause excessive menstrual bleeding. Hyperplasia and hypertrophy often occur together.

Metaplasia is a change into a form that is not normal for that cell. It also can be seen as the reversible replacement of normal tissue cells by other cells that may be better able to tolerate poor environmental conditions. An example of metaplasia is the change that occurs in the bronchial lining as a result of smoking. The normal ciliated epithelial cells are replaced by nonciliated squamous epithelial cells. The latter cells are more resistant to irritation. (*Bronchial metaplasia* can be reversed if the individual quits smoking.) Chronic inflammation of the cervix also can result in metaplasia.

Dysplasia is the development of abnormal changes in mature cells. The cells vary in size, shape, and color, and their relationship to one another also is abnormal. Dysplastic changes frequently are seen as precancerous. They occur most often in epithelial tissue. These changes often result from chronic irritation or inflammation. They frequently are found in cells near cancerous cells. Dysplasia is not considered a true cellular adaptation. Rather, it is seen as an atypical hyperplasia.

Cellular Injury

Many processes can injure a cell. The mechanisms involved in cellular injury are complex. The specific site of injury often is characteristic of a certain pathological process. As a rule, cellular injury occurs if the cell is unable to maintain homeostasis as a result of the following factors:

1. Hypoxic injury
2. Chemical injury
3. Infectious injury (e.g., bacteria, viruses)
4. Immunological and inflammatory injury
5. Genetic factors
6. Nutritional imbalances
7. Physical agents

HYPOXIC INJURY

Hypoxic injury is the most common cause of damage to a cell. It may result from a decrease in the amount of oxygen in the air, loss of hemoglobin or altered hemoglobin function, a decrease in the number of red blood cells, diseases of the respiratory or cardiovascular system, external compression (e.g., in trauma), or poisoning and loss of **cytochromes** (proteins in the liver that play a role in drug detoxification). Hypoxic injury commonly is a result of **atherosclerosis** (narrowing of the arteries) and **thrombosis** (complete blockage of an artery or a vein by a blood clot). Prolonged ischemia leads to **infarction,** or cell death (see Chapter 22). Atherosclerosis and thrombosis are leading causes of *myocardial infarction* and *stroke*.[7]

NOTE

Cells need an adequate supply of oxygen. Without oxygen they cannot generate enough energy to maintain the mechanisms (ion pumps) that move some substances across the cell membrane. Lack of oxygen also causes cellular swelling.

CHEMICAL INJURY

Many chemical agents can damage a cell. Examples include heavy metals (e.g., lead), carbon monoxide, ethanol, drugs, and complex toxins. Some of these chemicals injure cells directly (e.g., *curare* and *cyanide*). Others, when metabolized, produce a toxin that affects the cells (e.g., *carbon tetrachloride* [CCl_4]).

The injury begins with a biochemical interaction. The interaction occurs between a toxic substance and an integral part of the cell's structure. Some drugs and toxins (e.g., salicylate, certain venoms) affect the cellular membrane. This interaction can damage the plasma membrane. It can lead to increased permeability, cellular swelling, and irreversible cellular injury (see Chapter 32). Other toxins, such as carbon monoxide, mainly affect the cytochrome system found in the mitochondria. This leads to a halt in oxidative metabolism. Still other toxins affect the genetic material (a primary target for chemotherapeutic drugs).

INFECTIOUS INJURY

The **virulence** of microorganisms such as bacteria and viruses depends on their ability to survive and reproduce in the human body. The disease-producing potential of microorganisms depends on their ability to do the following:

- Invade and destroy cells
- Overcome the organism's defense system
- Produce toxins
- Produce hypersensitivity reactions

Bacteria. The survival and growth of bacteria are determined by the success of the body's defenses. They also depend on the bacteria's ability to resist these mechanisms (see Chapter 28). Many bacteria that survive and multiply in the body produce toxins. These can injure or destroy cells and tissues. The toxins take two forms: **exotoxins** (toxins secreted or excreted by a living organism) and **endotoxins** (toxins contained in the cell walls of some living organisms).

Bacteria make exotoxins when they have been identified by viruslike particles called *bacteriophages*. These particles carry the genetic material needed to make the toxin. Exotoxins are produced by a microorganism. Then they are excreted into the medium surrounding the microorganism. Exotoxins have highly specific effects. These effects are produced by the release of exotoxins as metabolic products during bacterial growth. Several of the *streptococci* (bacteria that cause sore throats and rheumatic fever) produce an exotoxin. The bacterium *Clostridium botulinum,* which causes the severe food poisoning known as **botulism,** also produces an exotoxin.

NOTE

Toxoids are modified (harmless) toxins. They are used as vaccines so that the body can develop specific **antibodies** to them. The best-known toxoid is *tetanus toxoid,* which is made from tetanus toxin.

Endotoxins are complex molecules. They are contained in the cell walls of some bacteria. Endotoxins are released during treatment with antibiotics or when the cell walls disintegrate. Examples of bacteria that produce endotoxins are *gonococci* and *meningococci*. (These are the bacteria that respectively cause gonorrhea and meningitis.) Endotoxins do not stimulate the production of strong antibodies. For this reason, it has not been possible to develop vaccines against endotoxin-bearing bacteria. Instead, to fight these bacteria, the body uses a group of proteins collectively called the **complement system.** These proteins coat the bacteria and then either help kill the microorganisms directly or aid neutrophils (in the blood) or macrophages (in the tissues) in the process of microorganism destruction. The *reticuloendothelial system* (composed of cells in the spleen, lymph nodes, liver, bone marrow, lungs, and intestines) works with the lymphatic system to dispose of the debris produced by the immune system's attack on invading organisms.

Bacteria that make endotoxins are also called *pyrogenic bacteria*. They are called this because they activate the inflammatory process. They also produce fever directly through the release of cell membrane toxins. As part of the inflammatory process, white blood cells are released from the bone marrow. This is the cause of the increased white blood cell count that is commonly found with infection. Inflammation also increases capillary permeability. This allows substances that destroy bacteria to migrate from the capillaries to the site of infection (see Chapter 28). Fever is caused by the release of *endogenous pyrogens* (proteins that act on the thermoregulatory centers of the hypothalamus). These proteins are released by macrophages or by circulating white blood cells that are attracted to the injury site.

CRITICAL THINKING
Will treating a fever with antipyretic drugs cause the body to rid itself of the toxin that caused the fever?

A **hypersensitivity reaction** is a life-threatening pathogenic mechanism of bacterial toxins. Few toxins are capable of producing this type of reaction. An immunological response occurs with the first exposure to the toxin. *Hypersensitivity* develops the next time the individual is exposed to the toxin. The result is an inflammatory response. At times, the response is so extreme that the person is killed instead of the bacteria. For example, the complement system can activate blood clotting and can cause white blood cells to aggregate and form "clumps," which block blood vessels.

The net effect of overactivation of the complement system by endotoxins is the blockage of small blood vessels in the lungs (with the clumps) and the formation of tiny blood clots in small arteries elsewhere in the body. Luckily, this life-threatening reaction is rare. Moreover, the complement system normally acts as an efficient defense against most bacterial toxins without causing any damage. (Hypersensitivity reactions are further described later in this chapter and in Chapter 27).

NOTE
When the body's defenses fail and microorganisms multiply in the blood, **bacteremia** develops. This may lead to *septicemia,* a severe systemic infection in which pathogens are present in the bloodstream. The endotoxins (along with a number of proteins involved in the inflammatory response) cause vasodilation. This reduces blood pressure and oxygen delivery. The result is shock. Other signs of an inflammatory response to bacteremia may include chills, fever, and an altered level of consciousness. Rashes or red streaks also may be associated with bacteremia. (The red streaks are called *lymphangitis.*)

CRITICAL THINKING
In septic shock, toxins damage the cell membrane, making it more permeable. This allows fluids to leak out of the blood vessels more freely. How could that affect cardiac output?

Viruses. Viruses cause many human diseases. These include the *common cold, influenza, chickenpox, smallpox, hepatitis, herpes,* and *acquired immunodeficiency syndrome* (AIDS). Viruses are intracellular parasites that work very differently from bacteria (Figure 11-16). Viruses lack much of the machinery that allows bacterial cells and other types of cells to grow rapidly and multiply. They can reproduce only by infecting the living cells of host tissue. (They often destroy the host cell.) Viruses usually consist of a protein coat (**capsid**) that encloses a core of nucleic acid. They have no organelles and therefore have no metabolism. They do not produce endotoxins or exotoxins.

Viruses need nucleic acid (either deoxyribonucleic acid [DNA] or ribonucleic acid [RNA]) to replicate. (Unlike all other cellular forms of life, viruses never have both DNA and RNA.) Cells are thought to engulf the virus particles by surrounding them with part of the cell membrane. Once inside the cell, the virus loses the capsid and begins to replicate the viral nucleic acids. Some viruses cause the cell to burst. Others replicate without destroying the cell.

The capsid enables the virus particle to resist **phagocytosis,** even though viruses often trigger a very strong immune response. Viruses can rapidly cause permanent and lethal injury in hosts, regardless of the host's state of immunosuppression. Rabies, smallpox, and influenza are examples of viral diseases that are highly infectious and that have high rates of illness (morbidity) and death (mortality).

NOTE
Phagocytosis is the process of ingestion of solid substances by cells. Substances ingested may include other cells, bacteria, pieces of necrosed (dead) tissue, and foreign particles.

Viral infections are easier to prevent than to treat. Vaccines have proven to be the best guard against viral disease (Box 11-6). Viral infections usually cause active illness. The

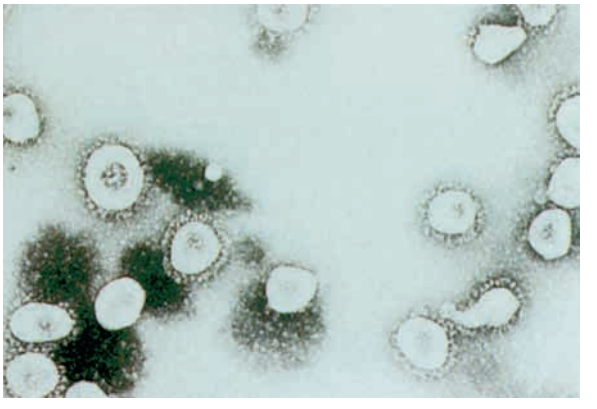

FIGURE 11-16 Coronavirus particles. (From U.S. Department of Health Education and Welfare, Public Health Service, Centers for Disease Control and Prevention, Atlanta, Ga.)

BOX 11-6 Influenza Vaccines

Influenza viruses are categorized into three major types: A, B, and C.

Type A mutates every 2 to 3 years. (Type A influenza viruses have caused worldwide epidemics, killing tens of thousands of people.) Type B mutates every 3 to 6 years. Type C apparently does not mutate. The mutations allow the virus to escape containment by the immune system. This is true even if a person had a previous influenza infection. Each year, virologists and epidemiologists analyze cultures from the southern hemisphere (where the flu season occurs during the northern hemisphere's summer). They try to determine which strains are likely to appear in the upcoming flu season and use this information to prepare effective vaccines. If the expected strain strikes, the vaccine can protect about 75% of those who have been vaccinated. It takes about 2 weeks after the vaccination to build antibodies (see Chapter 28).

signs and symptoms are based on the type and location of the cells infected. For this reason, certain viruses tend to cause respiratory illness (e.g., influenza). Others cause gastroenteritis (*enteroviruses*), central nervous system disease (e.g., *St. Louis B encephalitis, rabies*), or liver disease (*hepatitis*).

IMMUNOLOGICAL AND INFLAMMATORY INJURY

Cellular membranes are damaged by direct contact with cellular and chemical components of the immune and inflammatory responses. These components include phagocytic cells (*monocytes, neutrophils,* and *macrophages*) and substances such as *antibodies, lymphokines, complements,* and *proteases* (see Chapters 28 and 32). If the cell membrane is injured or if the transport mechanism (which moves potassium into the cell and sodium out of it) begins to fail, intracellular water level increases. This causes the cell to swell. If the swelling continues, the cell eventually may rupture.

INJURIOUS GENETIC FACTORS

Genetic disease results from a chromosomal abnormality or a defective gene. These genetic defects may be inherited. (An example of such a disease is *sickle cell anemia*.) They also may result from spontaneous mutations. (An example is *Down syndrome*.) Some genetic disorders can alter the cell's structure and function. Genetic disorders can cause changes in the structural or metabolic component of the specific target cells. *Huntington's disease* and *muscular dystrophy* are examples of conditions caused by such disorders (see Chapter 32).

NOTE

The term **congenital** refers to any abnormality that is present at birth. This is the case even though the abnormality may not be detected until much later.

INJURIOUS NUTRITIONAL IMBALANCES

Cells need adequate amounts of essential nutrients to function normally. If the needed nutrients are not obtained through the diet and transported to the cells, pathophysiological effects on the cells can occur. Damaging effects also can occur if excessive amounts of nutrients are consumed and transported to the cells. Examples of conditions caused by injurious nutritional imbalances include *protein-calorie malnutrition, obesity, hyperglycemia, scurvy,* and *rickets*.

INJURIOUS PHYSICAL AGENTS

Many physical agents can damage cells and tissues. Examples of physical agents (including environmental agents) that can cause cellular or tissue injury include the following:

- Temperature extremes (e.g., hypothermic and hyperthermic injury)
- Changes in atmospheric pressure (e.g., blast injury, decompression sickness)
- Ionizing radiation (e.g., radiation injury)
- Nonionizing radiation (e.g., radio waves, microwaves)
- Illumination (light injury [e.g., vision injury, skin cancer])
- Mechanical stresses (e.g., noise-induced hearing loss, overuse syndromes)

Manifestations of Cellular Injury

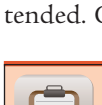
An injured cell may show various types of abnormalities in its form and structure. These are known as *morphological abnormalities*. The two most common abnormalities of this type are *cellular swelling* and *fatty change*. Cellular injury is indicated by both local and systemic signs.

CELLULAR MANIFESTATIONS

In injured cells (and in some healthy cells), several substances accumulate. They include fluids and electrolytes, triglycerides (lipids), glucose, calcium, uric acid, protein, melanin, and bilirubin. These substances normally are present in certain cells of the body. However, abnormal intracellular accumulation may lead to cellular damage. Also, injured cells may be unable to rid themselves of excessive amounts of water, sodium, or calcium. This leads to increased injury. If water, sodium, or calcium continues to accumulate, the cells become permanently damaged.

Macrophages ingest debris from injured cells. Some macrophages circulate throughout the body. Others remain fixed in tissues (e.g., the liver and the spleen). Phagocytes migrate to injured tissue. They engulf dying cells and abnormal extracellular substances. As more phagocytes migrate to injured tissue to engulf the metabolites, the affected tissue begins to swell. Phagocytosis by the fixed macrophages of the reticuloendothelial system causes enlargement of the liver (*hepatomegaly*) or the spleen (*splenomegaly*). This is seen with many diseases that are associated with abnormal accumulation of various metabolic products (*amyloidosis*) or abnormal cells (*hemolytic disease*).

Cellular Swelling. As described previously, the swelling in injured cells results from membrane changes that allow potassium to leak rapidly out of the cell and sodium and water to enter the cell. The increase in intracellular sodium concentration increases the osmotic pressure. This draws more water into the cell. If the swelling affects all cells in an organ, the organ increases in weight and becomes distended. Cellular swelling usually is reversible.



NOTE

Inflammation is associated with cellular swelling. This is true whether the cause is infection, trauma, or an autoimmune reaction. Inflammation is often accompanied by fever.

Fatty Change. Fatty change occurs when the enzyme systems that metabolize fat are impaired or overwhelmed. When this happens, lipids accumulate inside the cell. This is common in liver cells (*fatty liver*), because these cells are actively involved in the metabolism of fat. Hepatic metabolism and secretion of lipids are crucial to proper body function. For this reason, deficiencies in these processes lead to major pathological changes. Alcohol abuse is a common cause of fatty liver. It usually is a precursor to cirrhosis.

Systemic Manifestations. Cellular injury produces many systemic manifestations. These include fever, malaise, loss of well-being, change in appetite, altered heart rate, an abnormal rise in WBCs (**leukocytosis**), and pain. In addition, testing of extracellular fluid may reveal the presence of cellular enzymes released by injured cells or tissue.

Cellular Death and Necrosis

A cell dies if it has been irreparably damaged. Shortly after cell death, structural changes begin to occur in the nucleus and cytoplasm. The *lysosome* (a membranous sac of digestive enzymes found in many cells) begins to undergo membrane breakdown. This releases the lysosomal enzymes, which begin to digest the cell. The nucleus shrinks and dissolves or breaks into fragments (Box 11-7).

BOX 11-7 Normal Cellular Aging and Death

Cellular aging and death are common processes. They are natural functions of the cell cycle. As the cell ages, it becomes less efficient in executing its functions. It also is more at risk of damage from harmful environmental agents. With progressive damage, cells lose their ability to repair themselves. In time, they begin to malfunction. Changes in immunological cells slowly lead to decreased immunity and an increased risk of infectious disease. Malignancies increase with age as a result of decreased immunity. This also is due to an increased incidence of malignant transformation of various in cells. Other examples of the manifestations of aging in cells include gray hair, reduced muscle mass, menopause, arteriosclerosis, memory and vision impairment, and arthritis.

Necrosis is the death of cells or tissues caused by injury or disease. It also can occur by cellular self-destruction (**autolysis**). Different types of necrosis tend to occur in different organs or tissues. The type may indicate the cause of cellular injury. Necrotic changes take several hours to develop. They are easy to recognize on histological examination by their structure and staining characteristics.

HYPOPERFUSION

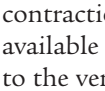
The term **hypoperfusion** is used to describe decreased circulation of blood and nutrients to tissues and organs. If this condition is prolonged, hypoperfusion can result in permanent cellular dysfunction and death. Hypoperfusion can be caused by a number of medical and traumatic conditions.

Pathogenesis

Hypoperfusion often is the result of a decrease in cardiac output. Decreased cardiac output, if prolonged, leads to **shock** (a continued state of hypoperfusion), *multiple organ dysfunction syndrome,* and other disease states associated with impaired cellular metabolism.

DECREASED CARDIAC OUTPUT

Cardiac output (also known as the *cardiac minute volume*) is the total amount of blood pumped by the ventricles each minute. It is usually expressed in liters per minute (L/min). Cardiac output is a crucial determinant of organ perfusion. It depends on several factors. These include the strength of contraction, the rate of contraction, and the amount of available blood returning through the veins (*venous return*) to the ventricles (**preload**).



NOTE

Cardiac output is determined by multiplying the heart rate by the stroke volume (i.e., the volume of blood ejected by the ventricles during each heartbeat). For example, if the ventricles contract 64 times per minute and eject 70 mL of blood with each contraction, the cardiac output would be 64 beats per minute multiplied by 70 mL per beat, or 4.48 L/min.

COMPENSATORY MECHANISMS

The body uses compensatory mechanisms to manage blood pressure and cardiac output. These include a number of **negative feedback mechanisms.** A negative feedback mechanism is any mechanism that tends to balance a change in a system. A number of negative feedback mechanisms are crucial to the process of maintaining cardiac output and tissue perfusion. These include baroreceptor reflexes, chemoreceptor reflexes, the central nervous system ischemic response, hormonal mechanisms, reabsorption of tissue fluids, and splenic discharge of stored blood (seen in animals but minimal in humans).

Baroreceptor Reflexes. As mentioned earlier, baroreceptors (Figure 11-17, *A*) are pressure-sensitive nerve endings found in the heart and great vessels. They keep blood pressure and cardiac output within a normal range.

Normal blood pressure produces a constant, low-level stimulation of the baroreceptors. When the blood pressure moves out of the normal range, either up or down, stimulation of the baroreceptors increases (Box 11-8). The baroreceptor reflexes then act to correct the condition. If the arterial blood pressure increases, the baroreceptor reflexes act to lower blood pressure. Likewise, if the arterial blood pressure decreases, the baroreceptor reflexes act to increase blood pressure (see Figure 11-17, *A*).[8] When baroreceptor stimulation ceases because of a fall in arterial pressure, the negative feedback mechanism evokes several cardiovascular responses (see Box 11-8). Vagal (parasympathetic) stimulation is reduced, and sympathetic response is increased. The increase in sympathetic impulses results in increased **peripheral vascular resistance** (PVR). It also results in an increase in the heart rate and stroke volume. Sympathetic responses also cause generalized arteriolar vasoconstriction. This reduces the size of the vascular compartment. As the veins constrict, blood is shifted into the central circulation. This, coupled with the constriction of blood vessels in the skin, muscles, and viscera, helps maintain perfusion of the central organs. The vasoconstriction in these peripheral vascular beds results in the characteristic pale, cool skin seen in patients suffering from *hypovolemic shock*.

NOTE

Peripheral vascular resistance is the resistance to blood flow in the systemic circulation (small arteries, arterioles, venules, veins). **Afterload** is the systemic vascular resistance on the left side of the heart. It is the pressure against which the left ventricle must contract to eject its contents.

BOX 11-8 Baroreceptor Responses to Changes in Blood Pressure: Sympathetic Nervous System

Baroreceptors (see Figure 11-17, *A*) help maintain blood pressure and cardiac output in two ways. Both of these are negative feedback mechanisms. Baroreceptors lower blood pressure in response to increased arterial pressure. They also increase blood pressure in response to decreased arterial pressure. Normal blood pressure partially stretches the arterial walls so that the baroreceptors produce a constant, low level frequency stimulation. This stimulation increases progressively from a lower pressure limit of 60 mm Hg to a maximum at 180 to 200 mm Hg. Impulses from the baroreceptors travel through the vagus and the Hering nerve to the glossopharyngeal nerve. There, they inhibit the vasoconstrictor center of the medulla. They also excite the vagal center. These impulses result in vasodilation in the peripheral circulatory system. They also cause a decrease in the heart rate and strength of contraction. The combined effect is a decrease in arterial pressure.

When low blood pressure stimulates a response in the baroreceptors, the effects on the heart include increases in the strength and rate of contraction. Peripheral effects include arteriolar constriction, decreased blood vessel size, and increased peripheral vascular resistance.

NOTE

Baroreceptors adapt within 1 to 3 days to the ambient pressure in the immediate locale. They therefore are not responsible for modulating the average blood pressure on a long-term basis.

Chemoreceptor Reflexes. When low arterial pressure leads to hypoxemia, acidosis, or both, peripheral chemoreceptor cells are stimulated. These are found in the carotid and aortic bodies. Because of the location of these bodies, the chemoreceptor cells have a vast blood supply. When the P_{O_2} or pH decreases, chemoreceptor cells stimulate the vasomotor center of the medulla. At the same time, the rate and depth of ventilation are increased. This helps to eliminate excess carbon dioxide. It also helps to maintain acid-base balance. Chemoreceptors (see Figure 11-17, *B*) are more involved in the regulation of respiration than in the regulation of the cardiovascular rate and rhythm or blood pressure. However, during profound hypotension or acidosis, chemoreceptors will produce vasoconstriction. This vasomotor stimulation results in enhanced peripheral vasoconstriction, which is initiated by the baroreceptors.

Central Nervous System Ischemic Response. Blood flow to the vasomotor center of the medulla can be reduced enough to cause ischemia. When this occurs, the neurons in the vasomotor center become excited. This raises the arterial blood pressure. This effect is known as the **central nervous system ischemic response.** The degree of sympathetic vasoconstriction can be intense. It can be so intense that it elevates the arterial pressure for as long as 10 minutes, sometimes to more than 200 mm Hg. If the ischemia lasts longer than a few minutes, the vagal centers are activated. This results in vasodilation in the periphery and *bradycardia* (a slowed heart rate). Like the chemoreceptor reflex, the central nervous system ischemic response functions only in emergency situations. Moreover, it does not become active until the arterial blood pressure falls below 50 mm Hg.

Hormonal Mechanisms. Several hormonal mechanisms also help to control arterial pressure through negative feedback. These include the adrenal medullary mechanism, the renin-angiotensin-aldosterone mechanism, and the vasopressin mechanism.

Adrenal Medullary Mechanism. When sympathetic stimulation of the heart and blood vessels increases, stimulation of the adrenal medulla also increases. The hormones secreted by the adrenal medulla are *epinephrine* and *norepinephrine*. The effect of these hormones on the cardiovascular system is very similar to that produced by the sympathetic nervous system. As a result, the heart rate, the stroke volume, and vasoconstriction increase.

Renin-Angiotensin-Aldosterone Mechanism. As described before, *renin* is an enzyme. It is released by the kidneys into the circulatory system. Renin changes the structure

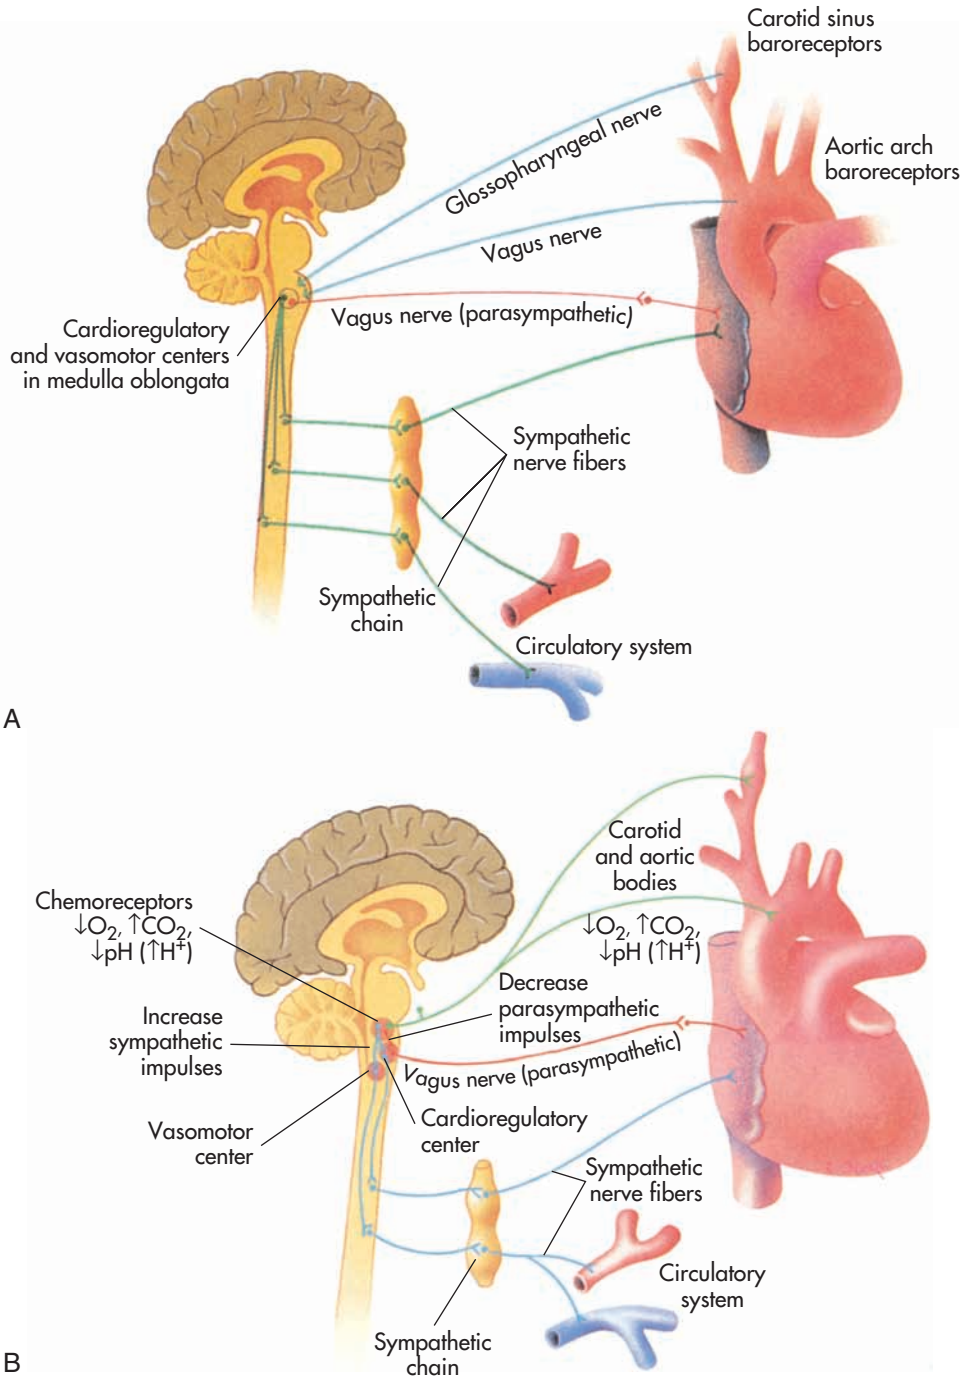


FIGURE 11-17 **A,** Baroreceptor reflexes. Baroreceptors in the carotid sinuses and the aortic arch detect changes in blood pressure. Impulses are conducted to the cardioregulatory and vasomotor centers. The heart rate can be decreased by the parasympathetic system; the heart rate and stroke volume can be increased by the sympathetic system. The sympathetic system can also constrict or dilate blood vessels. **B,** Chemoreceptor reflexes. Chemoreceptors in the medulla and carotid and aortic bodies detect changes in blood oxygen, carbon dioxide, or pH levels. Impulses are conducted to the medulla. In response, the vasomotor center can cause constriction or dilation of blood vessels through the sympathetic system, and the cardioregulatory center can cause changes in the pumping activity of the heart through the parasympathetic and sympathetic systems during emergency situations. Moreover, it does not become active until the blood pressure falls below 50 mm Hg.

of the plasma protein angiotensinogen, thereby producing angiotensin I. This, in turn, is converted by **angiotensin-converting enzyme** (mostly in the lungs), creating angiotensin II (active angiotensin).

NOTE

Angiotensin-converting enzyme (ACE) inhibitors are drugs that block the conversion of the precursor angiotensin I to the active molecule angiotensin II. As a result, blood pressure is lowered, and less stress is placed on the heart. Examples of ACE inhibitors include ***captopril*** (Capoten), ***enalapril*** (Vasotec), and ***lisinopril*** (Prinivil).

Angiotensin II causes vasoconstriction in the arterioles and to a lesser degree in the veins. This vasoconstriction results in increased peripheral vascular resistance, increased venous return to the heart, and a resultant increase in blood pressure. Angiotensin II also stimulates the release of aldosterone. Aldosterone acts on the kidneys to conserve sodium and water.

The renin-angiotensin-aldosterone mechanism is an important regulatory loop for increasing the blood pressure in circulatory shock. It takes about 20 minutes to become effective in hypovolemia caused by hemorrhagic shock. It remains active for about 1 hour.

CRITICAL THINKING

You are assessing your patient's radial pulse. What compensatory changes can you evaluate while doing this?

Vasopressin Mechanism. When the blood pressure drops or the concentration of solutes in the plasma increases (*increased serum osmolality*), the hypothalamic neurons are stimulated. This causes the anterior pituitary to increase secretion of vasopressin, or antidiuretic hormone (ADH). ADH acts directly on the blood vessels. It causes vasoconstriction within minutes after a rapid fall in the blood pressure. ADH also reduces the rate of urine production by enhancing reabsorption of water. This helps to maintain blood volume and blood pressure.

NOTE

Atrial natriuretic factor (ANF) also helps to control arterial pressure through a negative feedback mechanism. Its release is triggered by a rise in atrial pressure. (This is usually a sign of volume overload.) ANF increases the rate of urine production. Loss of water through the urine decreases blood volume. The result is a decrease in the atrial pressure. This is the only hormonal system actively used to decrease volume and pressure.

SHOW ME THE EVIDENCE

The brain natriuretic peptide (BNP) blood test is used to diagnose left ventricular failure (LVF). In 2001 researchers in Paris, France, conducted a prospective study to determine if this test could be used when treating prehospital patients complaining of difficulty breathing. A total of 52 adults older than 50 years who exhibited dyspnea were included (with some exclusions). During patient care, prehospital physicians categorized the cause of dyspnea as cardiac, respiratory, or uncertain. The BNP values did not affect treatment. BNP values were compared to the clinical diagnoses made by the physicians. All cardiac diagnoses were confirmed by BNP values. The BNP value established or corrected the original diagnosis in 33% of the cases, most frequently the uncertain patients. The authors concluded that BNP is a reliable indicator of LVF and that it appears to be a beneficial factor to enhance prehospital care. They cautioned that more studies are needed.

From Teboul A, Gaffinel A, Meune C, et al: Management of acute dyspnoea: use and feasibility of brain natriuretic peptide (BNP) assay in the prehospital setting, *Resuscitation* 61(1):91-96, 2004; doi: 10.1016/j.resuscitation.2003.12.005.

Reabsorption of Tissue Fluids. Arterial hypotension, arteriolar constriction, and reduced venous pressure during hypovolemia lower the blood pressure in the capillaries (*hydrostatic pressure*). This decrease promotes reabsorption of interstitial fluid into the vascular compartment. Large amounts of fluid may be drawn into the circulation during hemorrhage. It has been estimated that about 0.25 mL/min/kg of body weight, or 1 L/hr in the adult male, can be autoinfused from the interstitial spaces after acute blood loss.

Splenic Discharge of Blood. Some of the blood that circulates through the spleen continues through the microcirculation. It is stored in an area called the *venous sinuses*. The venous sinuses can store more than 300 mL of blood. Sudden reductions in blood pressure cause the sympathetic nervous system to stimulate constriction of these sinuses. Constriction can expel as much as 200 mL of this blood into the venous circulation to help restore blood volume or pressure in the circulation.

NOTE

An increase in preload or afterload or a decrease in stroke volume can lead to volume overload and pulmonary edema. This, in turn, can reduce tissue perfusion and impair cellular metabolism (see Chapter 22).

Types of Shock

Shock is classified according to the primary cause (Box 11-9). Although these classifications are separate and distinct, two or more types may be combined. Brief descriptions of the five types of shock are given here. A more detailed discussion of shock is presented in Chapter 36.

BOX 11-9 Common Etiological Classifications of Shock

Hypovolemic shock
Cardiogenic shock
Neurogenic shock
Anaphylactic shock
Septic shock

- *Hypovolemic shock* is most often caused by hemorrhage. It also may be caused by severe dehydration. In either case, circulating volume is lost.
- *Cardiogenic shock* results when the heart's pumping action cannot deliver adequate circulation for tissue perfusion.
- *Neurogenic shock* results most often from spinal cord injury that is accompanied by loss of sympathetic vasomotor tone.
- *Anaphylactic shock* occurs when the body is exposed to a substance that produces a severe allergic reaction.
- *Septic shock* most often results from a serious systemic bacterial infection.

Regardless of the classification, the underlying defect in shock is inadequate tissue perfusion.

Multiple Organ Dysfunction Syndrome

Multiple organ dysfunction syndrome (MODS) is the progressive failure of two or more organ systems. This occurs after a very severe illness or injury. Sepsis and septic shock are common causes of MODS. However, it may follow any period of prolonged shock, regardless of the cause (see Chapter 36).

NOTE

Multiple organ dysfunction syndrome (MODS) was first described in 1975. The death rate is 60% to 90%. The rate nears 100% if three or more organs are involved, if sepsis is present, and if the patient is older than 65 years.[9]

PATHOPHYSIOLOGY

Any process that triggers the body's inflammatory response may initiate MODS. (This includes traumatic, septic, and burn injury.) The syndrome begins with vascular endothelial damage. This damage is caused by the release of endotoxins and inflammatory mediators into the circulation. When the vascular endothelium is damaged, it becomes permeable. It allows fluid and cells to leak into the interstitial spaces. This, in turn, contributes to hypotension and hypoperfusion. The release of mediators activates three major plasma enzyme cascades, or processes: *complement, coagulation,* and *kallikrein/kinin*.

The plasma protein cascade systems are responsible for mediating the inflammatory response. Each system consists of a series of inactive enzymes (*proenzymes*). These are converted to active enzymes. This, in turn, initiates a cascade in which the *substrate* (a substance changed by an enzyme in a chemical reaction) of the activated enzyme is the next component of the system.

BOX 11-10 Clinical Manifestations of Multiple Organ Dysfunction Syndrome

After resuscitation (within 24 hours), a patient with multiple organ dysfunction syndrome (MODS) develops a low-grade fever, tachycardia, dyspnea, and altered mental status (confusion, altered level of consciousness). The lungs also begin to fail. This results in acute respiratory distress syndrome (ARDS). After 7 to 10 days, bacteremia commonly develops. Signs of kidney and liver failure appear as well. During days 14 to 21, renal and liver failure become severe, and the gastrointestinal (GI) and immune systems fail, followed by cardiovascular collapse. If the patient does not improve by the end of the third week, survival is unlikely. Death usually occurs between day 21 and day 28.

Complement activates phagocytes and induces further inflammation and damage to the endothelium. As a result of the endothelial damage, coagulation becomes uncontrolled. This results in the formation of microvascular thrombi and tissue ischemia. Activation of the kallikrein/kinin system releases *bradykinin* (a potent vasodilator), which contributes to low systemic vascular resistance. The overall effect of these three systems is a hyperinflammatory and hypercoagulable state that leads to edema formation, cardiovascular instability (hypotension), and clotting abnormalities. These inflammatory processes alter the normal pathways both of systemic blood flow and of blood flow in the individual organs. The result is a hyperdynamic circulation where the cardiovascular system responds to a decrease in PVR by an elevation in cardiac output that is above normal. It is also marked by an increase in the amount of blood returning to the heart through the veins. Blood is shunted past some regional capillary beds. Changes in capillary permeability allow the formation of interstitial edema. As a result, the delivery of oxygen to the tissues is decreased. In addition, the capillaries become blocked by tiny blood clots and by clumps of inflammatory cells. The resultant ischemia contributes to MODS.

The same hormonal responses that help conserve volume in shock cause the body to enter into a hypermetabolic (*catabolic*) state, altering carbohydrate, fat, and lipid metabolism to meet the increased demand for energy. In time, the sympathetic drive and the hyperdynamic circulation place great demands on the heart. The net result is depletion of oxygen and fuel supplies. The decrease in oxygen delivery to the cells, the hypermetabolism, and the associated myocardial depression create an imbalance in oxygen supply and demand. This is soon followed by tissue hypoxia with cellular acidosis and impaired cellular function. Finally, multiple organ failure begins (Box 11-10 and Figure 11-18).

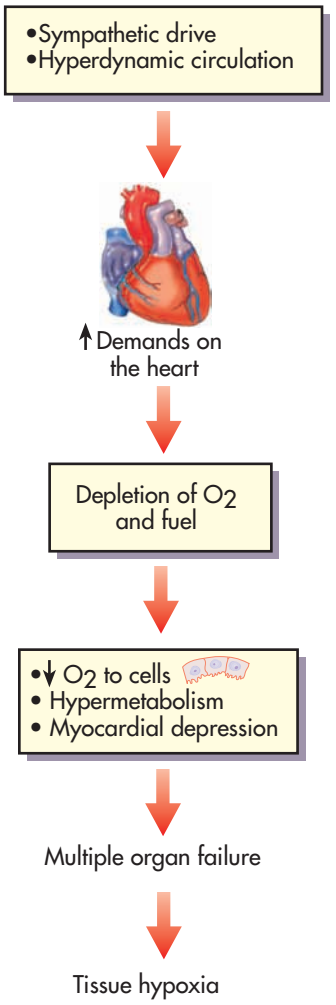

FIGURE 11-18 Multiple organ dysfunction syndrome.

No specific therapy exists for MODS. However, early detection is critical, because it allows supportive measures to be started at once.

Impairment of Cellular Metabolism

Energy is required for nearly all of the cellular activities that support life. The active transport pumps in the cell membrane consume a large portion of the cell's energy. They use this energy to maintain a normal fluid and electrolyte composition inside the cell. Adenosine triphosphate (ATP) and other high-energy phosphate molecules provide the fuel for all the energy-related functions of the cell. In the healthy body, most cellular metabolism is aerobic metabolism. Anaerobic metabolism occurs when the metabolic need for energy exceeds the oxygen supply. However, anaerobic metabolism can supply only a small fraction of the energy produced by aerobic metabolism. (Anaerobic metabolism generates 2 ATP molecules for every molecule of glucose. Aerobic metabolism generates 36 ATP molecules for every molecule of glucose.) By itself, anaerobic metabolism cannot meet the body's energy needs.

Glucose is a key fuel for the production of energy. It is really the only fuel that can be used anaerobically under conditions of cellular hypoxia (as occurs in a state of shock). Under these conditions, glucose is metabolized to *lactate* and *pyruvate*. This produces a net sum of 2 ATP molecules. If oxygen is present (aerobic metabolism), pyruvate enters the **Krebs cycle.** This is a sequence of reactions that breaks down a molecule of pyruvic acid into molecules of carbon dioxide and water (Figure 11-19). The Krebs cycle is 18 times more efficient at producing ATP than is glycolysis. (Glycolysis is the breakdown of glucose to lactate.) The Krebs cycle cannot occur in the absence of oxygen. Anaerobic production of ATP is inefficient. Thus, with anaerobic metabolism, the rate of **glycolysis** must be greatly increased to meet the body's energy demands. This leads to an increase in the production of lactic acid and resultant metabolic acidosis.

As tissue metabolites (and hydrogen ions) continue to accumulate, they stimulate vasodilation. This vasodilation opposes the previously described hormonally regulated constriction of the precapillary sphincters, thereby reducing the body's ability to continue vital tissue perfusion by maintaining the proper size of the vascular compartment. (The *postcapillary sphincters* are more resistant to the vasodilating effects of tissue metabolites. They stay constricted long after the *precapillary sphincters* dilate.) This in turn increases the capillary hydrostatic pressure. The result is fluid loss from the vascular space into the interstitial space. In addition, the insufficient energy production of anaerobic metabolism affects the cell's ability to maintain a normal sodium-potassium differential across the cell membrane. Intracellular potassium leaks out of the cell; sodium leaks into the cell. This creates cellular swelling and a decreased transmembrane potential. Energy production is further impaired. Finally, the cells are irreversibly damaged.

SELF-DEFENSE MECHANISMS

The body's first lines of defense against illness and injury are the external barriers. These include the skin and the mucous membranes of the digestive, respiratory, and genitourinary tracts. These structures form a barrier between the internal organs and the environment (see Chapter 28). When they are breached, chemicals, foreign bodies, or microorganisms are allowed to enter cells and tissues. The second and third lines of defense then are activated. These are the **inflammatory response** and the **immune response,** respectively.

Inflammatory Response

Inflammation is a local reaction to cellular injury. The response may be triggered by physical, thermal, or chemical damage. It also may be caused by microbial infection. When a microbial invasion occurs, this line of defense is activated. It prevents further invasion of the pathogen by isolating, destroying, or neutralizing the microorganism. As a rule, the response is protective and is considered beneficial. However, if the response is sustained or directed toward the host's own **antigens,** healthy tissue may be destroyed.

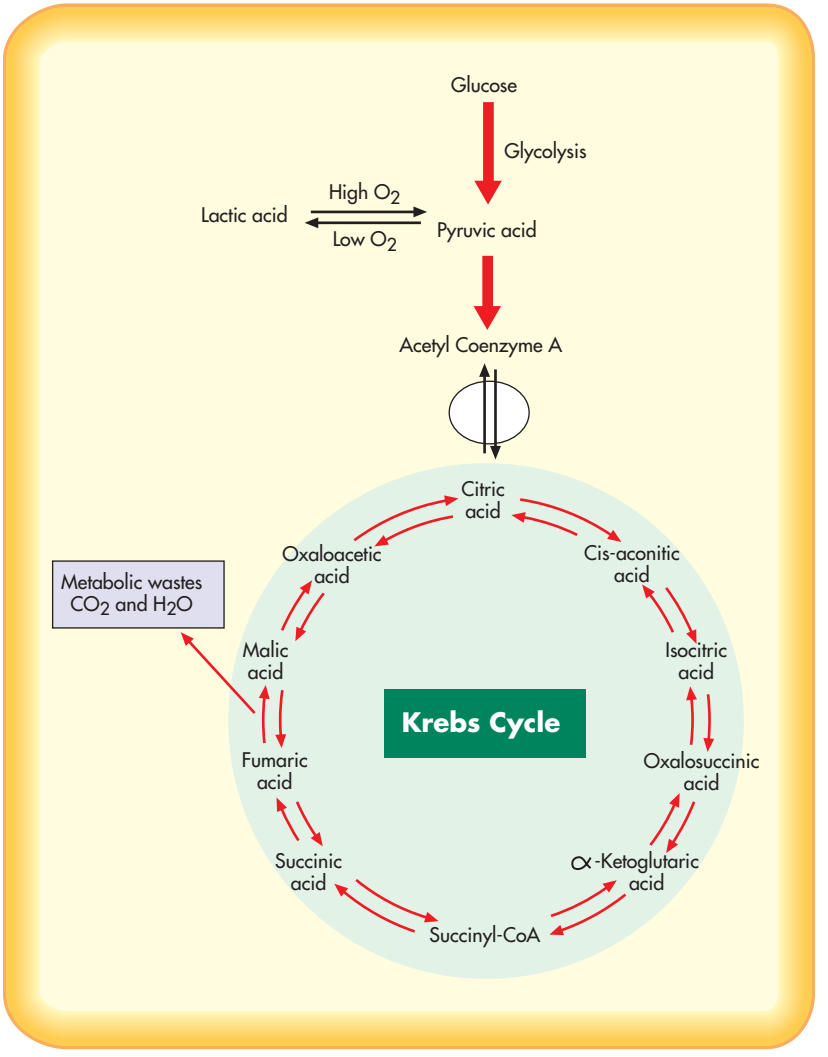

FIGURE 11-19 Krebs cycle.

NOTE

An antigen is a substance (usually a protein) that causes the formation of an antibody. The antigen reacts specifically with that antibody. Specific antibodies bind to specific antigens when the two fit together. The attachment of antibodies aids in the neutralization of antigens. It also aids in their removal from the body.

STAGES OF THE INFLAMMATORY RESPONSE

The inflammatory response may be divided into three separate stages. These are the *cellular response to injury,* the *vascular response to injury,* and *phagocytosis*.

Cellular Response to Injury. Metabolic changes occur with any type of cellular injury. The most common primary effect of cellular injury is damage to the cell's aerobic metabolism and ATP-generating process (*oxidative phosphorylation*). This leads to a decrease in energy reserves. When the energy sources are depleted, the sodium-potassium pump can no longer work effectively. The cell begins to swell as sodium ions accumulate. The organelles in the cell also swell. This swelling, along with increasing acidosis, leads to further impairment of enzyme function. It also leads to further deterioration of the cell's membranes. In time, the membranes of the cellular organelles begin to leak. The release of hydrolytic enzymes by the lysosomes contributes further to cellular destruction and autolysis. As the cellular contents are dissolved by enzymes, the inflammatory response is stimulated in surrounding tissues.

Vascular Response to Injury. After cellular injury, localized **hyperemia** (an increase in organ blood flow) develops as the surrounding arterioles, venules, and capillaries dilate. The associated increase in filtration pressure and capillary permeability causes fluid to leak from the vessels. It leaks into the interstitial space. This creates edema. Leukocytes (particularly neutrophils and monocytes) begin to collect along the vascular endothelium. As a result of the release of **chemotactic factors** (chemicals that attract white blood cells to the site of inflammation), they soon migrate to the injured tissue.

Phagocytosis. As described earlier, *phagocytosis* is the process by which leukocytes engulf, digest, and destroy pathogens. The circulating macrophages are also responsible for clearing the injured area of dead cells and other debris. *Intracellular phagocytosis* is the ingestion of bacteria and dead cell fragments. It occurs at the site of tissue invasion. It may extend into the general circulation if the infection becomes systemic. Intracellular phagocytosis stimulates the release of chemicals that induce lysis of the leukocytes. These leukocytes combine with dead organisms, proteins, and fluid to form an inflammatory exudate (commonly known as *pus*). This exudate is a by-product of the inflammatory process associated with bacterial infection. Exudate may be watery (serous exudate), as is seen with blisters; thick and clotted (*fibrinous exudate*), as is seen with lobar pneumonia; or pus filled (*purulent exudate*), as is seen with cysts or abscesses. If bleeding occurs, the exudate is described as *hemorrhagic exudate*.

CRITICAL THINKING

Consider these signs or symptoms: heat, redness, pain, and swelling. What pathophysiological inflammatory response causes each of these?

MAST CELLS

As described in Chapter 10, **mast cells** are specialized cells (Figure 11-20). They are widely distributed throughout connective tissues. Their cytoplasm is filled with granules containing *vasoactive amines* (histamine, serotonin) and chemotactic factors. When tissue is injured, the mast cells discharge their granules (*degranulation*) as part of the inflammatory response. Mast cell degranulation is stimulated by physical injury (e.g., thermal or mechanical trauma), chemical agents (e.g., toxins, snake and bee venoms), or hypersensitivity reactions. It also may be a direct result of the activity of complement components.

LOCAL AND SYSTEMIC RESPONSE TO ACUTE INFLAMMATION

Acute inflammation may be characterized by both local and systemic effects (Figure 11-21). Local responses

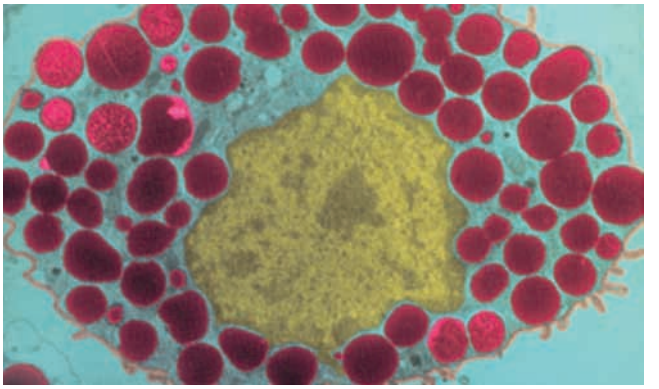

FIGURE 11-20 Mast cell in bone marrow. (From Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

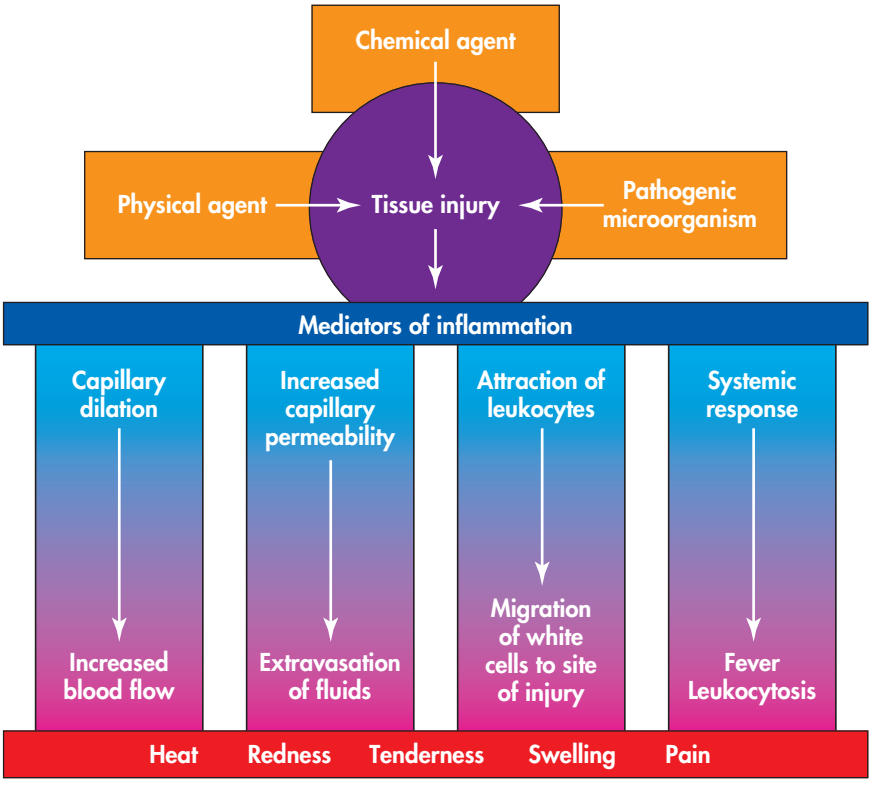

FIGURE 11-21 Inflammation. (Modified from Crowley L: *Introduction to human disease,* ed 3, Boston, 1992, Jones & Bartlett.)

include vascular changes (vasodilation and increased vascular permeability) and the formation of exudate. Systemic responses include fever, leukocytosis, and an increase in the level of circulating plasma proteins. The characteristic signs of localized inflammation are heat, redness, tenderness, swelling, and pain.

RESPONSES TO CHRONIC INFLAMMATION

Chronic inflammation lasts 2 weeks or longer. It can result from a persistent acute inflammatory response. This type of response may be caused by bacterial contamination by a foreign body (e.g., wood splinter, glass), persistent infection, or continued exposure to an antigen. If the inflammatory process is severe or prolonged, the body attempts to repair or replace tissue that has been damaged. The body produces connective tissue fibers and new blood vessels for use in the repair process. If the area of tissue destruction is large, scar tissue forms.

Immune Response

The skin and the inflammatory response are the first two defense mechanisms the body uses to protect itself from injurious agents (see Chapter 27). They respond to every agent using the identical nonspecific mechanism. The immune response, however, is specific to each individual pathogen. Immunity may be natural, present at birth, or acquired. *Acquired immunity* develops through exposure to a specific antigenic agent or pathogen. It can be induced through vaccination (immunization) against certain infectious diseases. An example of such a disease is measles.

Acquired immunity is further classified as humoral immunity and cell-mediated immunity. *Humoral immunity* is associated with the production of antibodies that combine with and eliminate foreign material. *Cell-mediated immunity* is characterized by the formation of a group of lymphocytes that attack and destroy foreign material (see Chapter 28). Cell-mediated immunity is the body's best defense against viruses, fungi, parasites, and some bacteria. It also is the mechanism the body uses to reject transplanted organs.

CRITICAL THINKING

Consider hepatitis, feline leukemia, and chickenpox. What kind of immunity protects you from each of these infections?

NOTE

The immune response is affected by age. Most infants are born with enough natural immunity to protect themselves from disease until they have made their own antibodies. However, the cells of the immune system become less efficient with age. Older people become more susceptible to disease. The aging immune system also becomes less able to eliminate abnormal cells that may develop.

INDUCTION OF THE IMMUNE RESPONSE

As defined previously, an *antigen* is a substance that reacts with preformed components of the immune system. For example, it may react with lymphocytes and antibodies. An antigen may be a molecule or a molecular complex. An *immunogen* is a specific type of antigen, one that also can bring about, or induce, the formation of antibodies. (Some antigens, therefore, are not immunogens because they are unable to induce the immune response.) To be immunogenic, the antigenic molecule must be:

- Sufficiently foreign to the host
- Sufficiently large
- Sufficiently complex
- Present in sufficient amounts

The immune response is triggered after foreign materials have been cleared from the area of inflammation. After phagocytes digest the pathogens, antigenic material appears on their surface. The antigen is recognized by receptors on lymphocytes as foreign, or "non-self." Then, a chain of events is set in motion to destroy or neutralize the antigen. Briefly, this involves two primary changes that occur among the lymphocytes. Some mature into plasma cells (derived from **B lymphocytes**), which produce antibody. Others mature into sensitized lymphocytes (**T lymphocytes**). These are capable of interacting directly with the foreign antigen to neutralize or destroy it. (The immune response is presented in more detail in Chapters 27 and 28.)

BLOOD GROUP ANTIGENS

In the early 1900s researchers discovered that human blood had individual variations. A donor's blood was separated into plasma and red blood cell components and mixed with separated blood samples from another donor. Two reactions were noted. When combined with foreign plasma, the red cells either clumped together (*agglutinated*) or showed no change. Scientists also found that two distinct *agglutinins* (substances on red blood cells that act as antigens) were responsible for the clumping. Based on possible combinations of these antigens, four types of human blood were identified: A, B, AB, and O (Figure 11-22).

Type A blood has anti-B antibodies in the plasma. It therefore clumps type B blood. Type B blood has anti-A antibodies. It therefore clumps type A blood. Type AB blood has neither antibody. Therefore people with this blood type can be given any of the four types of blood (*universal recipient*). Type O blood has both anti-A and anti-B antibodies but no antigens. It can therefore be given to patients with any blood type. Type O blood has become known as the *universal donor*.

NOTE

Immune tolerance refers to the immune system's ability to allow self-antigens (versus non–self-antigens) to exist by preventing their recognition by lymphocytes and antibodies.

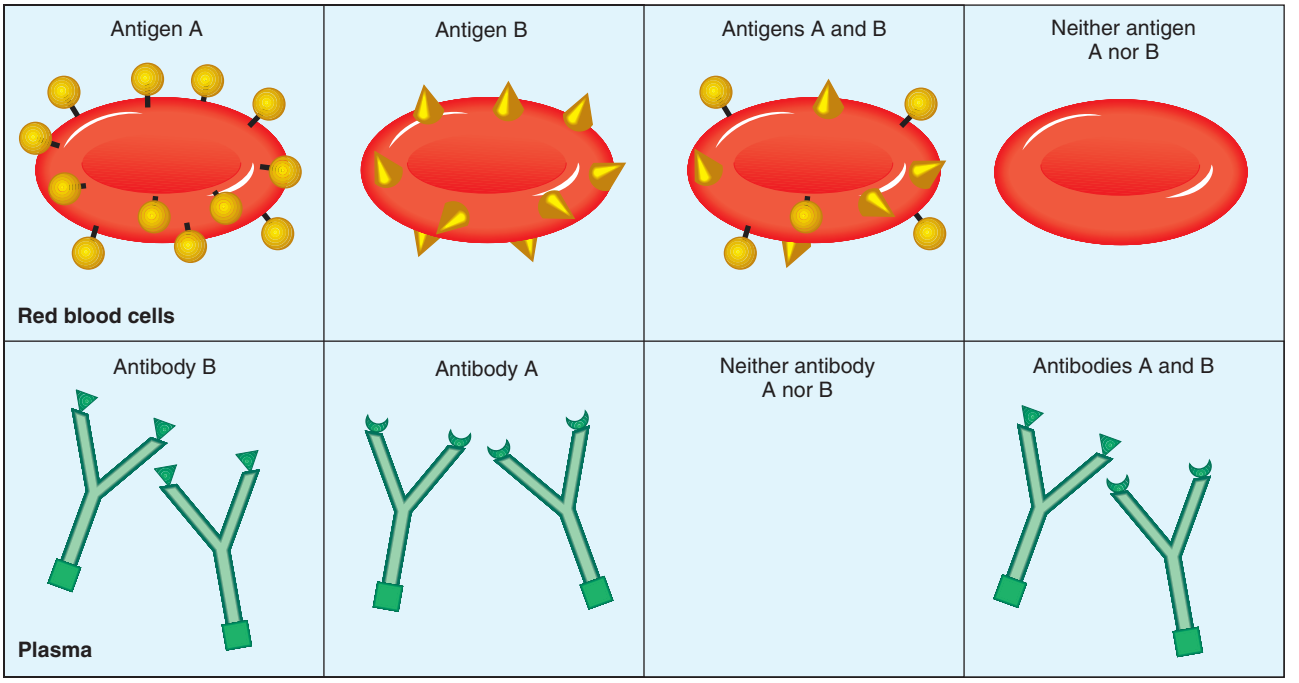

FIGURE 11-22 ABO blood groups. In type A blood, the red blood cells have type A surface antigens and the plasma has type B antibodies. In type B blood, the red cells have type B surface antigens and the plasma has type A antibodies. In type AB blood, the red cells have both type A and type B surface antigens but no plasma antibodies. In type O blood, the red cells have no ABO surface antigens but the plasma has A and B antibodies.

SHOW ME THE EVIDENCE

This group investigated the use of a hemoglobin-based oxygen carrier for prehospital resuscitation of trauma patients. A total of 714 injured patients with a systolic BP of ≤90 mm Hg were randomly given either PolyHeme or crystalloid fluid for resuscitation. They found no statistically significant difference in death rates at 30 days between the two groups. There were more adverse effects in the PolyHeme group. The researchers propose that PolyHeme may be considered as a substitute when blood is not available.

From Moore EE, Moore FA, Fabian TC, PolyHeme Study Group, et al: Human polymerized hemoglobin for the treatment of hemorrhagic shock when blood is unavailable: the USA multicenter trial, *J Am Coll Surg* 208(1):1-13, 2009.

Rh FACTOR

In the late 1940s another determinant in human blood was discovered: the **Rh factor.** (The acronym Rh was taken from the word rhesus, the species of monkey used in the research.) Researchers found that when the blood of a rhesus monkey was injected into a rabbit, the rabbit's immune system developed antibodies. When a sample of the rabbit's plasma was mixed with a sample of human red blood cells, the human cells usually agglutinated (*Rh positive*). About 85% of Americans have Rh-positive blood. Incompatibility between Rh-positive and Rh-negative blood can cause a harmful immune response (e.g., through transfusion or during childbirth). The percentages of ABO and Rh blood groups in the general population are as follows:

O positive	38.4%
O negative	7.7%
A positive	32.3%
A negative	6.5%
B positive	9.4%
B negative	1.7%
AB positive	3.2%
AB negative	0.7%

VARIANCES IN IMMUNITY AND INFLAMMATION

The immune responses usually are protective. They help to protect the body from harmful microorganisms and other injurious agents. At times, however, these responses may be inappropriate. They may even have undesirable effects.

Hypersensitivity: Allergy, Autoimmunity, and Isoimmunity

Hypersensitivity is an altered immunological reactivity to an antigen. It results in a pathological immune response upon reexposure. These abnormal responses include allergy, autoimmunity, and isoimmunity. **Allergy** refers to an exaggerated immune response that is provoked by

environmental allergens. **Autoimmunity** is an immune response against the host's own cells. (These are *self-antigens*.) **Isoimmunity** is an immune response directed against beneficial foreign tissues. (Examples of these are blood transfusions and transplanted organs.) Of these three responses, allergy is the most common. It also is the least life-threatening (see Chapter 27).

Autoimmunity and isoimmunity are responsible for some diseases, including the following:

- Graves' disease
- Rheumatoid arthritis
- Myasthenia gravis
- Immune thrombocytopenic purpura
- Isoimmune neutropenia
- Systemic lupus erythematosus (SLE)
- Rh and ABO isoimmunization
- Multiple sclerosis (MS)

MECHANISMS OF HYPERSENSITIVITY

Hypersensitivity reactions may be immediate or delayed. With *immediate hypersensitivity,* antibodies present in the serum trigger an antigen-antibody reaction upon reexposure. Mild reactions of this type include itching and hives. Severe reactions may include life-threatening respiratory distress and **anaphylaxis** (see Chapter 27).

Delayed hypersensitivity reactions are a product of cell-mediated immunity. In these reactions, the body develops hypersensitivity after exposure to a foreign antigen from bacteria, parasites, or other microorganisms. The reaction may take from several hours to 2 days to appear and may reach maximal severity several days later. An example of a delayed hypersensitivity reaction is the response against grafted tissue. The results of a brush with poison ivy are a more common example.

IgE Reactions. Antibodies, or *immunoglobulins (Ig),* are produced by plasma cells in response to antigenic stimulation. Five distinct classes of immunoglobulins are produced in humans (Box 11-11). IgE accounts for less than 1% of the antibodies in normal serum. It is responsible for immediate (type I) hypersensitivity reactions. With type I reactions, the response is mediated through IgE, which is bound to mast cells or basophils. When an antigen reacts with an IgE molecule bound to a mast cell or circulating basophil, these cells promptly release a host of chemical mediators into the extracellular space. The target organs and the manifestations of the reaction vary, ranging from hives to hay fever to asthma to life-threatening anaphylaxis (see Chapter 27).

NOTE

Hypersensitivity reactions are divided into four distinct types: *type I* (IgE-mediated allergic reactions), *type II* (tissue-specific reactions), *type III* (immune complex–mediated reactions), and *type IV* (cell-mediated reactions). These types are further described in Chapters 13 and 27.

BOX 11-11 Classes of Immunoglobulins

IgG Immunoglobulins

IgG immunoglobulins account for 70% to 75% of the antibodies in normal serum. IgG is most abundant in blood. However, it also is found in lymph, cerebrospinal, synovial, and peritoneal fluid and breast milk. It is the main antibody involved in secondary immune responses. IgG is the only immunoglobulin that crosses the placenta. It provides temporary immunity in neonates.

IgM Immunoglobulins

IgM immunoglobulins account for about 5% to 10% of the antibodies in normal serum. Most anti-A or anti-B antibodies are of the IgM class. IgM triggers the increased production of IgG in acute infections and the complement fixation required for an effective antibody response.

IgA Immunoglobulins

IgA immunoglobulins account for about 15% of the antibodies in normal serum. This immunoglobulin is found in blood, secretions such as tears and saliva, and the respiratory tract, stomach, and accessory organs. IgA combines with a protein in the mucosa and defends body surfaces against invading microorganisms.

IgE Immunoglobulins

IgE immunoglobulins account for less than 1% of the antibodies in normal serum. IgE is found in some tissues and on the surface membranes of basophils and mast cells. IgE is responsible for immediate hypersensitivity reactions.

IgD Immunoglobulins

IgD immunoglobulins account for less than 1% of the antibodies in normal serum. The precise biological function of IgD is unknown.

Immunity and Inflammation Deficiencies

Immunity and inflammation deficiencies describe the failure of these mechanisms of self-defense to function at normal capacity. The source of the deficiency may be *congenital* (present at birth) or *acquired*. Acquired immune deficiencies may be caused by infection. Examples include the human immunodeficiency virus (HIV), cancer (in particular the leukemias), immunosuppressive drugs, and aging. Whether the source is congenital or acquired, the deficiency usually is caused by a disruption in the function of the lymphocytes, although neutrophil dysfunction also has been described. Research is underway to find replacement therapies for immune deficiencies (Box 11-12).

ACQUIRED DEFICIENCIES

Acquired immune deficiencies are far more common than congenital forms (Box 11-13). They may be classified into the following groups:

- Nutritional deficiencies (e.g., severe deficits in calorie or protein intake)

BOX 11-12 Replacement Therapies for Immune Deficiencies

Intravenous replacement of infection-fighting antibodies
Transplantation of tissue
Blood transfusions
Gene therapy (technology still in infancy)

BOX 11-13 Acquired Immune Deficiencies

The following are associated with acquired immune deficiencies:

- Pregnancy
- Infancy
- Infection (e.g., maternal rubella during pregnancy [congenital], maternal cytomegalovirus infection [during pregnancy], measles, leprosy, tuberculosis)
- Down syndrome
- Malignancies (e.g., Hodgkin's disease, leukemia, myeloma)
- Stress caused by surgery or emotional trauma
- Malnutrition
- Aging
- Diabetes
- Alcoholic cirrhosis
- Sickle cell anemia
- Immunosuppressive treatment
- Anesthesia

From McCance K, Huether S: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.

- Iatrogenic deficiencies (deficiencies caused by some form of medical treatment)
- Deficiencies caused by trauma (e.g., bacterial infection, burns)
- Deficiencies caused by stress (depressed immune function)
- Acquired immunodeficiency syndrome (AIDS)

NOTE

Acquired immunodeficiency syndrome (AIDS) currently is the best-known example of acquired dysfunction of the immune system. The human immunodeficiency virus (HIV) causes AIDS. It results in a debilitating illness that is manifested by various opportunistic infections and malignancies. Until recently, these were almost always fatal. The disease was first identified in 1981. Since then it has become a global health problem. It affects an estimated 33 million people worldwide[10] (see Chapter 28).

CRITICAL THINKING

Think about a time when you or someone close to you became ill because of an acquired immune deficiency. What kind of deficiency caused it? Was it preventable?

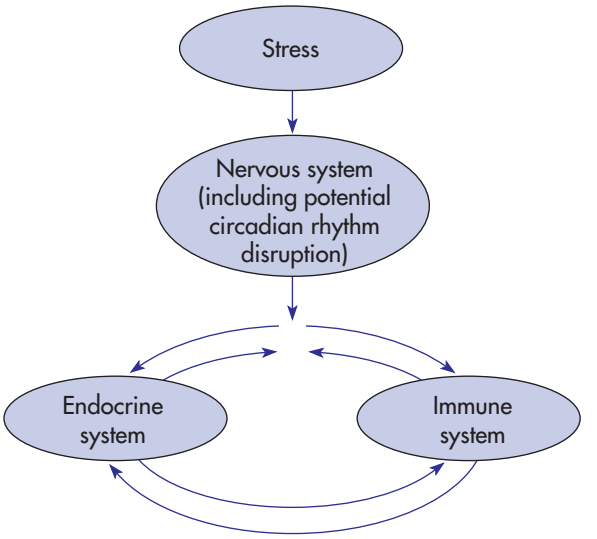

FIGURE 11-23 Interaction of the emotional state, the central nervous system, and the body's defense against infection and abnormal cell division.

STRESS AND DISEASE

Prolonged emotional or psychological stress can result in physical illness. This type of illness can produce disturbances in three important areas: cognition, emotion, and behavior. The growing evidence of the link between stress and disease has created a field of science called psychoneuroimmunology. *Psychoneuroimmunology* is the study of the three-way interaction of the emotional state, the central nervous system, and the body's defense against external infection and abnormal cell division (Figure 11-23).

Neuroendocrine Regulation of Stress

As described in Chapter 2: Well-Being of the Paramedic, the sympathetic nervous system is activated during the stress response. Stress causes the adrenal glands to release catecholamines (epinephrine, norepinephrine, and dopamine) into the bloodstream (Table 11-4). At the same time, the hypothalamus stimulates the pituitary gland to release the hormones ADH, prolactin, growth hormone, and adrenocorticotropic hormone (ACTH). ACTH, in turn, stimulates the cortex of the adrenal gland to release cortisol (Table 11-5).

CATECHOLAMINES

Catecholamines act by stimulating two major classes of receptors. These are **alpha-adrenergic receptors** and **beta-adrenergic receptors.** These two classes are further subcategorized into *alpha-1 receptors, alpha-2 receptors, beta-1 receptors,* and *beta-2 receptors*.

- Alpha-1 receptors are postsynaptic. They are located on the effector organs (e.g., blood vessels, skeletal muscle). The main role of the alpha-1 receptors is to stimulate the contraction of smooth muscle. The alpha-2 receptors are found on the presynaptic nerve endings. Stimulation of

TABLE 11-4 Physiological Effects of Catecholamines*

Organ	Process or Result
Brain	Increased blood flow
	Increased glucose metabolism
Cardiovascular system	Increased rate and force of contraction
	Peripheral vasoconstriction
Pulmonary system	Increased oxygen supply
	Bronchodilation
	Increased ventilation
Muscle	Increased glycogenolysis
	Increased contraction
	Increased dilation of skeletal muscle vasculature
Liver	Increased glucose production
	Increased gluconeogenesis
	Increased glycogenolysis
	Decreased glycogen synthesis
Adipose tissue	Increased lipolysis
	Increased fatty acids and glycerol
Skin	Decreased blood flow
Skeleton	Decreased glucose uptake and utilization (decreases insulin release)
Gastrointestinal and genitourinary tracts	Decreased protein synthesis
Lymphoid tissue	Increased protein breakdown (lymphoid tissue shrinks)

From McCance K, Huether S: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.
*Some of these responses require the presence of glucocorticoids (e.g., cortisol) for maximal activity.

the alpha-2 receptors serves as a negative feedback mechanism by inhibiting further release of norepinephrine.

- The beta-1 receptors are located mainly in the heart. Beta-2 receptors are located primarily in the bronchiolar and arterial smooth muscle. The beta receptors perform a number of functions. They stimulate the heart; dilate bronchioles and blood vessels in skeletal muscle, brain, and heart; and aid in glycogenolysis. Epinephrine activates both the alpha and the beta receptors (Table 11-6); norepinephrine mainly excites the alpha receptors. (Alpha and beta receptors are discussed in more detail in Chapter 13.)

CORTISOL

Cortisol (hydrocortisone) circulates in the plasma. It mobilizes substances that are needed for cellular metabolism. The main metabolic effect of cortisol is the stimulation of gluconeogenesis. It also enhances the elevation of blood glucose level. It does this by reducing glucose utilization. Cortisol also acts as an *immunosuppressant;* it reduces the reproduction of lymphocytes, particularly among the T lymphocytes. This, in turn, leads to a decrease in cellular immunity.

Cortisol also reduces the migration of macrophages into an inflamed area. It reduces phagocytosis, partly by stabilizing the lysosomal membranes. This decrease in immune cell activity may be beneficial, because it prevents immune-mediated tissue damage. Two factors determine whether cortisol's effects are adaptive or destructive. These factors are the type of stress event and the length of exposure to the stressor.

Role of the Immune System

Many immunological conditions and diseases seem to be triggered by stress (Table 11-7). However, the exact mechanisms that link stress to these diseases and conditions have not yet been clearly defined. It is believed that the immune, nervous, and endocrine systems communicate through complex pathways. Also, they may be affected by factors involved in the stress reaction.

Interrelationship of Stress, Coping, and Illness

As noted earlier in this chapter and in Chapter 2, the damage caused by stress is determined by the nature, intensity, and duration of the stressors. It also is affected by the way in which a person perceives the stressors and how well the individual is able to cope with them. The ability to notice the signs and symptoms of stress and to use stress management tactics is crucial to good health. Stress-reduction techniques include meditation, exercise, and guided imagery. In healthy individuals, such methods can help prevent harmful physiological and psychological illness arising from stress.

GENETICS AND FAMILIAL DISEASES

People are born with a genetic predisposition to the development of certain diseases. The genetics of some diseases, like *hemophilia* or *sickle cell anemia,* are well understood (see Chapter 32). Patients either have no genetic predisposition, are carriers of the disease, or have the disease. Other disease processes (like *arthritis, diabetes,* and *hypertension*) certainly are linked to genetics, but are strongly associated with environmental factors as well. Medical researchers attempt to reduce the incidence or severity of these inherited medical conditions through environmental manipulation.

Factors Causing Disease

Factors that cause disease may be simplistically classified as *genetic* or *environmental*. However, there is a strong interaction between the two (Box 11-14). For example, genes cannot exert their effects without an environment in which to operate, and environmental factors act differently on different people. Conversely, the environment may be the same, but people have unique genetic makeups. Therefore the interaction between genetics and environment is very complex.

TABLE 11-5 Physiological Effects of Cortisol

Function	Effects
Carbohydrate and lipid metabolism	Diminishes peripheral uptake and utilization of glucose; promotes gluconeogenesis in liver cells; enhances gluconeogenic response to other hormones; promotes lipolysis in adipose tissue
Protein metabolism	Increases protein synthesis in liver and depresses protein synthesis (including immunoglobulin synthesis) in muscle, lymphoid tissue, adipose tissue, skin, and bone; increases plasma level of amino acids; stimulates deamination (an oxidative reaction) in liver
Inflammatory function	Decreases circulating eosinophils, lymphocytes, and monocytes; increases release of polymorphonuclear leukocytes from bone marrow; decreases accumulation of leukocytes at site of inflammation; delays healing; permissive for vasoconstrictive action of norepinephrine
Lipid metabolism	Promotes lipolysis in extremities and lipogenesis in face and trunk
Immune reserve	Decreases tissue mass of all lymphoid tissues (e.g., decreases protein synthesis); promotes rapid decrease in circulating lymphocytes, eosinophils, basophils, and macrophages; inhibits production of interleukin-1 and interleukin-2 and consequently blocks cell-mediated immunity and generation of fever
Digestive function	Promotes gastric secretion
Urinary function	Enhances urinary excretion
Connective tissue	Decreases proliferation of fibroblasts in connective tissue (thereby delaying healing)
Muscle	Maintains normal contractility and maximal work output for skeletal and cardiac muscle
Bone	Decreases bone formation
Vascular system and myocardial function	Maintains normal blood pressure; increases responsiveness of arterioles to constrictive action of adrenergic stimulation; optimizes myocardial performance
Central nervous system	Modulates perceptual and emotional functioning (although mechanism for this is unknown), which are essential for normal arousal and initiation of daytime activity

Modified from McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.

TABLE 11-6 Physiological Actions of Alpha and Beta Receptors

Receptor	Physiological Actions
Alpha-1 receptor	Increased glycogenolysis; smooth muscle contraction (blood vessels, genitourinary tract)
Alpha-2 receptor	Smooth muscle relaxation (gastrointestinal tract); smooth muscle contraction (some vascular beds); inhibition of lipolysis, renin release, platelet aggregation, and insulin secretion
Beta-1 receptor	Stimulation of lipolysis, myocardial contraction (increased rate, increased force of contraction)
Beta-2 receptor	Increased hepatic gluconeogenesis; increased hepatic glycogenolysis; increased muscle glycogenolysis; increased release of insulin, glucagon, and renin; smooth muscle relaxation (bronchi, blood vessels, genitourinary tract, gastrointestinal tract)

Modified from McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.

GENETIC FACTORS

Heredity is governed by the laws of chance and probability. This exists because each pair of chromosomes is sorted at random when packaged into eggs and sperm. More than 100,000 genes are involved in a person's genetic makeup. Thus the range of variation is huge. Different types of genetic diseases can arise. These can occur because of individual genetic changes or because of abnormalities involving an entire chromosome.

Sometimes mistakes occur when chromosomes are packaged. This results in rearrangement of the chromosomes. Entire chromosomal abnormalities lead to diseases such as *Down syndrome* or *Turner's syndrome*. More often, only a single gene on the chromosome is passed on, resulting in an abnormal protein. This is the type of genetic defect responsible for sickle cell anemia and hemophilia. Some conditions may involve more than one gene (i.e., they are *polygenic*) and a number of factors, but they still may have a strong inherited component. These diseases include *coronary artery disease* (CAD), hypertension, and cancer.

NOTE

Genes are not unchangeable units of inheritance. Under some circumstances, they can be affected by environmental influences (see Box 11-14).

TABLE 11-7 Examples of Stress-Related Diseases and Conditions

Target Organ or System	Disease or Condition
Cardiovascular system	Coronary artery disease
	Hypertension
	Stroke
	Disturbances of heart rhythm
Muscles	Tension headaches
	Muscle contraction backache
Connective tissues	Rheumatoid arthritis (autoimmune disease)
	Related inflammatory diseases of connective tissue
Pulmonary system	Asthma (hypersensitivity reaction)
	Hay fever (hypersensitivity reaction)
Immune system	Immunosuppression or deficiency
	Autoimmune diseases
Gastrointestinal system	Ulcer
	Irritable bowel syndrome
	Diarrhea
	Nausea and vomiting
	Ulcerative colitis
Genitourinary system	Diuresis
	Impotence
	Frigidity
Skin	Eczema
	Neurodermatitis
	Acne
Endocrine system	Diabetes mellitus
	Amenorrhea
Central nervous system	Fatigue and lethargy
	Type A behavior (impatience, competitive/aggressive attitude)
	Overeating
	Depression
	Insomnia

From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 4, St Louis, 2002, Mosby.

BOX 11-14 Example of Environmental Influence in Genetic Selection

The gene that causes sickle cell anemia was recognized to be much more common in environments in which malaria was prevalent. People with sickle cell disease have sickle-shaped red blood corpuscles, which clog the capillaries. This condition often proves fatal. However, in people who are carriers of the sickle cell trait, fewer than 1% of the red corpuscles are abnormal. These individuals do not die of sickle cell anemia, and they are more resistant to malaria than those who do not carry the sickle cell trait. Thus the trait proved protective, and its prevalence increased as a result of natural selection.

ENVIRONMENTAL FACTORS

Many common chronic diseases may occur because of a mismatch between genetic and environmental factors (Tables 11-8 and 11-9). Important environmental factors include the following:

- Microorganisms and immunological exposure
- Personal habits and lifestyle
- Chemical substances
- Physical environment
- Psychosocial environment

The goal in preventing disease is to find the genetic and environmental influences that lead to major diseases. This knowledge will help individuals who have specific susceptibilities. They will be able to change certain environmental factors. This, in turn, may lessen their risk of developing the illness.

AGE AND GENDER

Age and gender also seem to play a role in the incidence of *familial* (hereditary) diseases. This is especially true for diseases that are not caused by a single genetic defect. In the

TABLE 11-8 Environmental Factors That Affect the Occurrence of Disease

Factors	Examples
Microorganisms and immunological exposure	Bacteria
	Viruses
	Fungi
	Protozoa
	Vectors (e.g., insects and animals)
	Allergens
Personal habits and lifestyle	Smoking
	Physical exercise
	Dietary intake
Chemical substances	Toxins
	Pollutants
	Medications
	Solvents, fumes
	Contaminants
Physical environment	Climate
	Radiation
	Physical trauma
	Geographic location (e.g., sun exposure, altitude)
	Community (e.g., water and food supplies)
Psychosocial milieu	Family status (e.g., bereavement, loss, status change)
	Stress
	Coping skills
	Social isolation
	Ethnic and racial customs
	Religious customs

TABLE 11-9 Populations with Shared Disease Tendencies*

Disease	Rate Among Populations	Suggested Environmental Factors	Shared Gene Pool
Early coronary artery disease	Very high in Finland (very low in Japan)	Animal fat intake	Genes for high blood cholesterol
Colon cancer	Low in developing countries (e.g., Africa); high in "westernized" countries (e.g., United States, Europe)	Dietary fiber and fat intake	None
Thalassemia (a type of anemia)	High in individuals of Mediterranean descent; low in other areas	None	Major dominant gene for thalassemia
Malaria (and many other infectious diseases)	High in some parts of Africa and Asia; low in United States and Europe	Trypanosomes, mosquitoes, disease control measures	None
Early non–insulin-dependent diabetes and obesity	Native Americans	Change from scarce food supply to plenty	Apparent shared gene pool among various Native American tribes
Lung cancer	Low in Mormons and Seventh Day Adventists	Health code forbids use of tobacco	None
Skin cancers	Higher among Caucasians than African Americans; higher in "Sun Belt"	Ultraviolet light	Inherited level of skin pigmentation

From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2010, Mosby.
*These tendencies are the result of shared environmental factors, a common gene pool, or both.

polygenic disorders, the combined effects of genes and environment over time play a role. These combined influences may result in diseases linked to age-related changes in metabolism. This may explain why heart disease, hypertension, and cancer are seen more often in people older than age 40.

Gender is associated with sex-specific diseases that arise from hormonal and anatomical differences. Two examples are breast cancer in women and testicular cancer in men. Lifestyle and environmental differences in gender-related activities also may play a role. These differences may be responsible for the predisposition to some diseases. Examples of gender, lifestyle, and environmental combinations include the higher rate of lung cancer and coronary artery disease in men who smoke cigarettes.

Analyzing the Risk of Disease

Epidemiologists are researchers who study disease "rates" and analyze risk factors. Disease rates help to describe the occurrence of disease. Risk factors are indicators of a person's predisposition to development of a disease.

DISEASE RATES

Three statistics are commonly used to assess the impact of a disease on a society. These are the incidence rate, the prevalence rate, and the mortality rate. The *incidence rate* refers to the number of new cases detected during a given period per the number of people in the population surveyed. The period is usually 1 year. The *prevalence rate* refers to the number of people *living* with the disease per the number of people in the population surveyed. The *mortality rate* refers to the number of people who died from the disease during a given period per the number of people in the population surveyed. The given period, again, is often 1 year.

RISK FACTOR ANALYSIS

The presence of certain risk factors in any group of people is linked to an increased disease rate in that group. Diseases may have *causal* and *noncausal* risk factors. With causal risk factors, removal or elimination of the risk factors delays or prevents the disease. Noncausal risk factors can help predict a person's chances of developing the disease, but they have no direct effect on the underlying cause (Figure 11-24). Risk factors cannot precisely predict whether a person will develop a disease. However, they can provide clues about the individual's likelihood of developing the disease.

Combined Effects and Interaction of Risk Factors

When one or more risk factors interact, the individual effects of risk factors may be greatly magnified. For example, some risk factors alone may pose little or no danger of disease. However, if another risk factor is added, the danger increases substantially.

FAMILIAL DISEASE TENDENCY

In some cases the members of a family (brothers and sisters, parents with children, spouse pairs, twins) are more prone

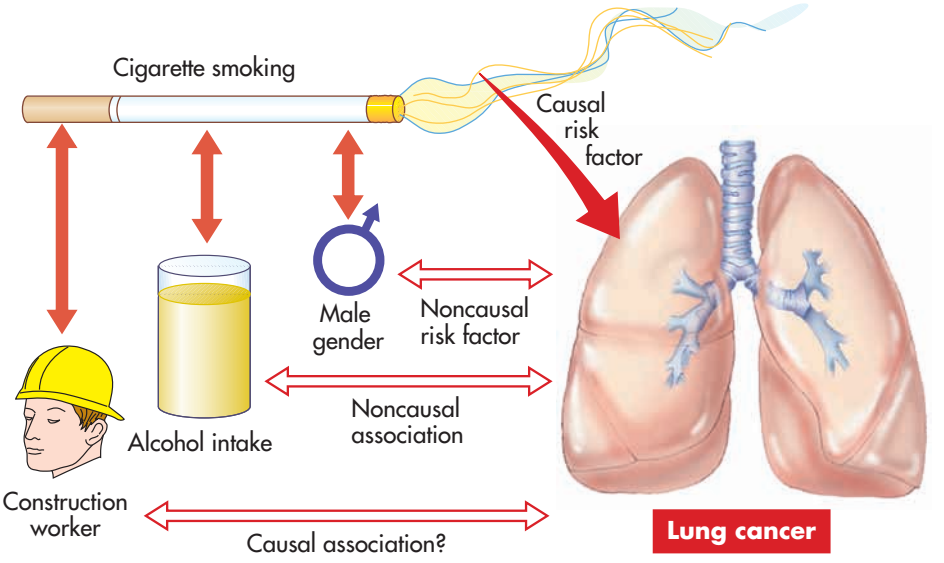

FIGURE 11-24 Causal and noncausal risk factors and associations.

to some diseases than are the people of the general population. Often the familial risk factors are genetic or shared factors in the environment. Examples include illnesses such as heart disease and pulmonary disease. These result from decisions such as choosing to smoke or consuming a diet high in fat.

CRITICAL THINKING

Think about how many risk factors you have for heart disease. Which of these factors are genetic and which ones could you eliminate by modifying your habits or environment?

AGING AND AGE-RELATED DISORDERS

Advanced age is a risk factor for many diseases, such as heart attack, stroke, and cancer. This likely represents the cumulative effects of genetics and environmental factors. Disorders related to age occur throughout life (Table 11-10). Some disorders, such as dental cavities and "strep throat," are more common in younger age groups. The degenerative disorders (e.g., arthritis) are more common in older age groups.

Common Familial Diseases and Associated Risk Factors

Individuals who are high risk can take steps to avoid many familial diseases (Table 11-11). Examples of such diseases include coronary artery disease and colorectal cancer. These conditions are described in detail throughout this text.

TABLE 11-10 Age-Related Disorders

Age	Disorders
Birth to 14 years	Congenital disorders
	Allergy
	Infection
	Cancer (leukemia, Wilms' tumor, medulloblastoma, retinoblastoma)
	Trauma or injury
	Diabetes (early onset)
15 to 30 years	Allergy (asthma)
	Endocrine disorders
	Trauma or injury (suicide)
	Venereal disease
31 to 40 years	Ulcer
	Hypertension
	Breast cancer
	Homicide
	Suicide
	Complications of pregnancy
	Alcoholism
41 to 60 years	Heart disease (hypertension, rheumatic disorder, infarction)
	Kidney disease (glomerular nephritis)
	Liver disease (cirrhosis)
	Cancer (lung, colon, breast, ovary)
61 to 80 years	Cardiovascular disease
	Cancer (lung, colon, prostate)
81 to 100 years	Cancer (leukemia, lymphoma, prostate cancer)
	Dementia (Alzheimer's disease, Parkinson's disease)
	Osteoporosis
	Infection
	Cardiovascular disease
	Trauma or injury (fracture)

Modified from King DW, Fenoglio CM, Lefkowitch JH: *General pathology: principles and dynamics,* Philadelphia, 1988, Lea & Febiger.

TABLE 11-11 Common Familial Diseases and Associated Environmental Risk Factors

Disease	Environmental Risk Factors
Immunological Disorders	
Asthma and other allergies	Fur, dust, pollen, mold (other allergens)
Rheumatic fever	Group A *Streptococcus* bacterial infection
Cancer	
Breast cancer	Obesity, high dietary fat intake, alcohol ingestion, hormones
Colorectal cancer	Inadequate fiber intake, high dietary fat intake
Lung cancer	Cigarette smoke, environmental pollutants
Endocrine Disorders	
Diabetes mellitus type 1 (insulin-dependent)	Viral infection, longstanding difficulty (years) controlling blood glucose level
Diabetes mellitus type 2 (non–insulin-dependent)	Obesity; high-sugar, low-fiber dietary intake; longstanding difficulty (years) controlling blood glucose level
Hypertension	Diet, obesity, inadequate exercise (sedentary lifestyle)
Hematological Disorders	
Drug-induced hemolytic anemia	Aspirin, antibiotics, infection
Sickle cell anemia	Precipitated by cold weather, infection
Hemochromatosis	Ingestions (iron), transfusions
Cardiovascular Disorders	
Coronary artery disease	Exercise, alcohol ingestion, diet high in fat and salt, smoking, obesity, stress
Cardiomyopathies	Infection, ingestion of alcohol or use of other drugs
Mitral valve prolapse	Infection
Hypertension and stroke	Diet high in fat and salt, obesity
Renal Disorders	
Gout	Poor diet, injury, stress
Kidney stones	Decreased water intake
Gastrointestinal Disorders	
Malabsorption Disorders	
Lactose intolerance	Ingestion of milk products
Ulcerative colitis	Stress, consumption of trigger foods
Crohn's disease	Stress, consumption of trigger foods
Peptic ulcers	Stress, diet that causes gastric irritation, infection
Gallstones	High dietary fat intake, obesity
Obesity	Diet high in fat, sugar, and total calories; stress that affects appetite; cultural perceptions
Neuromuscular Disorders	
Multiple sclerosis	Virus, warm environment (heat-producing exercise, warm ambient temperature), stress
Alzheimer's disease	Decreased mental stimulation later in life
Psychiatric Disorders	
Schizophrenia	Uncertain influence; dramatic success with drug treatment
Manic depression	Uncertain influence; dramatic success with drug treatment

SUMMARY

- Two facts illustrate the importance of body water. First, body water is the medium in which all metabolic reactions occur. Second, the precise regulation of the volume and composition of body fluids is essential to health. Water follows osmotic gradients established by changes in sodium concentrations. Thus sodium balance and water balance are closely related.
- Two abnormal states of body fluid balance can occur. If the water gained exceeds the water lost, a state of water excess, or overhydration, exists. If the water lost exceeds the water gained, a state of water deficit, or dehydration, exists.
- In addition to fluid imbalances, disturbances in the balance of electrolytes (other than sodium) may occur. These electrolytes include potassium, calcium, and magnesium. Imbalances of these electrolytes can interfere with neuromuscular function. They may even cause cardiac rhythm disturbances.
- The treatment of isotonic dehydration may include volume replacement with isotonic or occasionally hypotonic solutions. The treatment of hypotonic dehydration may involve intravenous replacement with normal saline or lactated Ringer's solution. Occasionally hypertonic saline (e.g., in seizures caused by hyponatremia) is used. Interventions for overhydration depend on the cause. These interventions may include water restriction, administration of a diuretic, or, if hyponatremia is present, administration of saline.
- In-hospital treatment of hypokalemia involves intravenous or oral potassium replacement. Management of hyperkalemia may involve potassium restriction, enteral administration of a cation exchange resin, or intravenous administration of glucose and insulin, sodium bicarbonate, or calcium.
- Treatment of hypocalcemia involves intravenous administration of calcium ions. The management of hypercalcemia may include controlling the underlying disease, hydration, and, occasionally, drug therapy such as with furosemide and other calcium-lowering drugs.
- Hypomagnesemia typically is corrected by the administration of intravenous magnesium sulfate. The most effective treatment for hypermagnesemia is hemodialysis. Calcium salts that antagonize magnesium may also be given.
- The healthy body is sensitive to changes in the concentration of hydrogen ions (pH). It tries to maintain the pH of extracellular fluid at 7.4. This is accomplished through three interrelated compensatory mechanisms: carbonic acid–bicarbonate buffering, protein buffering, and renal buffering.
- Metabolic acidosis occurs when the amount of acid generated exceeds the body's buffering capacity. The four most common forms of metabolic acidosis encountered in the prehospital setting are lactic acidosis, diabetic ketoacidosis, acidosis resulting from renal failure, and acidosis caused by ingestion of toxins. Treatment for metabolic acidosis is aimed at correcting the underlying cause.
- Loss of hydrogen is the initial cause of metabolic alkalosis. This may be caused by vomiting (hydrochloric acid loss), suctioning of gastric contents, or increased renal excretion of hydrogen ion in the urine. Treatment is directed at correcting the underlying condition. Volume depletion, if present, should be corrected with isotonic solutions.
- Respiratory acidosis is caused by the retention of carbon dioxide. This leads to an increase in the P_{CO_2}. This condition usually is caused by an imbalance in the production of carbon dioxide and its elimination through alveolar ventilation. Treatment for respiratory acidosis involves improving ventilation quickly to eliminate carbon dioxide.
- Hyperventilation may produce respiratory alkalosis by decreasing the P_{CO_2}. Treatment of respiratory alkalosis is directed at correcting the underlying cause of the hyperventilation. An initial approach is to administer low-concentration oxygen to the patient. Another is to provide calming measures to assist the patient with slow, controlled breathing.
- An understanding of the processes of disease is crucial. This requires a knowledge of the structural and functional reactions of cells and tissues to injurious agents. Changes in cells and tissues can be caused by adaptation, injury, neoplasia, aging, or death.
- An injured cell may have an abnormal physical shape or size. Cell injury has both cellular and systemic indications.
- Certain factors cause disease. For the most part, these factors may be classified as genetic or environmental. However, a strong interaction occurs between the two.
- The term hypoperfusion is used to describe inadequate tissue circulation. Hypoperfusion may result from decreased cardiac output. Decreased cardiac output can lead to shock, multiple organ dysfunction syndrome, and other disease states associated with impaired cellular metabolism. Negative feedback mechanisms important in maintaining cardiac output and tissue perfusion are baroreceptor reflexes, chemoreceptor reflexes, the central nervous system ischemia response, hormonal mechanisms, reabsorption of tissue fluids, and splenic discharge of stored blood.
- The external barriers are the body's first line of defense against illness and injury. These barriers include the skin and the mucous membranes of the digestive, respiratory, and genitourinary tracts. When these barriers are breached, chemicals, foreign bodies, or microorganisms are allowed to penetrate cells and tissues. Then the second and third lines of defense are activated. These

Continued

are the inflammatory response (second) and the immune response (third). Both the external barriers and the inflammatory response respond to all organisms using the identical nonspecific mechanism. The immune response is specific to individual pathogens.

- Immune responses usually are protective. They help to protect the body from harmful microorganisms and other injurious agents. At times these responses may be inappropriate. They may even have undesirable effects. Examples of inappropriate responses include hypersensitivity and immunity or inflammation deficiencies.
- Many immune-related conditions and diseases are associated with stress. However, the exact mechanisms causing these illnesses have not yet been clearly defined. It is believed that the immune, nervous, and endocrine systems communicate through complex pathways and that they may be affected by factions involved in the stress reaction.
- Factors that cause disease are complex. They may involve genetic or environmental factors or a combination of both. Age and gender also influence illness.

CHAPTER

12 Life Span Development

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the normal vital signs and body system characteristics of the newborn, neonate, infant, toddler, preschooler, school-aged child, adolescent, young adult, middle-aged adult, and older adult.
2. Identify key psychosocial features of the infant, toddler, preschooler, school-aged child, adolescent, young adult, middle-aged adult, and older adult.
3. Explain the effect of parenting styles, sibling rivalry, peer relationships, and other factors on a child's psychosocial development.
4. Discuss the physical and emotional challenges faced by the older adult.

KEY TERMS

adolescent A person 13 to 18 years of age.

attachments Physical and emotional bonds that develop between infants and their family members or caregivers.

Babinski reflex A reflex movement in which the great toe bends upward when the outer edge of the sole is stroked.

cognitive development The construction of thought processes, including remembering, problem solving, and decision making, from childhood through adolescence to adulthood.

early adulthood People 20 to 40 years of age.

family function The ways a family deals with daily problems and conflicts and whether this is done in a respectful, productive, and nonaggressive way.

infant A child 28 days to 1 year of age.

late adulthood People 61 years of age or older.

masturbation Sexual stimulation, especially of one's own genitals, often to the point of orgasm.

menarche The first menstruation and the commencement of the cyclic menstrual function.

menopause The cessation of menses.

middle adulthood People 41 to 60 years of age.

Moro reflex A normal infant response elicited by a sudden loud noise. The infant flexes the legs, makes an embracing gesture with the arms, and usually gives a brief cry.

neonate An infant in the first 28 days of life.

newborn An infant within the first few hours of life.

passive immunity Immunity acquired by transmission of antibodies from the mother, through placental transfer, to the fetus; a form of acquired immunity in which antibodies against disease are acquired naturally.

periodontal disease Disease that affects tissues that surround or support the teeth.

preschooler A child 3 to 5 years of age.

palmar grasp The curling of an infant's fingers in response to a touch on the palm of the hand; it is a normal infant response.

puberty The period of life when the ability to reproduce begins.

reciprocal socialization A term that refers to a child's temperament and the responses it elicits from adults and family members. This interaction forms the basis for early social interactions with others and with the child's environment.

reproductive maturity The time at which a person has attained the ability to reproduce.

rooting reflex A normal infant response elicited by touching or stroking the side of the cheek or mouth; this causes the infant to turn the head toward that side and to begin to suck.

school age The age group comprising children 6 to 12 years.

self-concept The accumulation of knowledge about one's self; including beliefs regarding personality traits, physical characteristics, abilities, values, goals, and roles.

self-esteem A person's overall evaluation or appraisal of his or her own worth.

separation anxiety A normal period during development in which a child experiences anxiety when separated from the primary caregiver.

sibling rivalry Jealousy or competitiveness between brothers and sisters.

sucking reflex A normal infant response in which touching the infant's lips with the nipple of a breast or bottle causes involuntary sucking movements.

temperament A person's style of behavior; the way the person interacts with the environment. It is the basis on which children develop relationships.

terminal drop A theory that a decline in intelligence in older adulthood may be caused by the person's conscious or unconscious perception of coming death.

toddler A child 1 to 3 years of age.

Paramedics provide care to patients from all age groups. Often a patient's complaints are directly related to the growth and developmental characteristics common for that person's age group. Therefore, it is important that paramedics study and understand the physiological and psychosocial development of human beings at different stages in life.

(Courtesy Monroe Yancie, St Louis, Mo.)

NOTE

Age groups and developmental characteristics are defined in the *EMS Education Standards*.[1] These are general descriptions of development across the life span. They may differ slightly from other references in this and other textbooks. The age groups presented in this chapter are infants (birth to 1 year of age); toddlers (1 to 3 years of age); preschoolers (3 to 5 years of age); school-age children (6 to 12 years of age); adolescents (13 to 18 years of age); early adulthood (20 to 40 years of age); middle adulthood (41 to 60 years of age); and late adulthood (61 years of age or older).

NEWBORN

The term **newborn** is used for infants in the first few hours of life (Figure 12-1). A child younger than 28 days is known as a **neonate.** The term **infant** is used for a child 28 days to 1 year of age.

Vital Signs

During the first 30 minutes of life, the newborn's heart rate is 100 to 200 beats per minute (bpm). By 1 year of age, the heart rate averages 120 bpm. At birth, the respiratory rate usually is 40 to 60 breaths/minute. This rate drops to 30 to 40 breaths/minute within a few minutes after delivery. By 1 year of age, a rate of 25 breaths/minute is considered normal. The average systolic blood pressure increases from 70 mm Hg at birth to 90 mm Hg at 1 year. Body temperature during infancy ranges from 98° to 100° F (36.7° to 37.8° C).

FIGURE 12-1 Newborn. (Courtesy Ben Sanders, O'Fallon, Mo.)

CRITICAL THINKING

Why are newborn, infant, and neonate considered distinct stages?

Weight

A full-term newborn normally weighs 3 to 3.5 kg (7 to 8 pounds). The baby's head accounts for about 25% of the total body weight; its circumference is equal to that of the baby's chest. For the first few days of life, the total body weight may decrease 5% to 10% as a result of excretion of *extracellular fluid* (fluid outside the cells). By the second week of life, the birth weight has been regained, and the child's weight exceeds the newborn weight. Although some babies gain weight faster than others, most gain an average of 140 to 168 g (5 to 6 ounces) per week. The increase in an infant's body weight should follow a steady upward curve at about 30 g (1 ounce) per day during the first month of life (this will double the birth weight within 4 to 6 months and triple it within 9 to 12 months). Monitoring the infant's weight every few weeks is a good way to keep track of development.

NOTE
One kilogram (kg) is equal to 2.2 pounds (lb). One gram (g) is equal to $\frac{1}{480}$ ounce (oz). These and other equivalents are described in Chapter 14.

CRITICAL THINKING
What considerations for patient care are necessary based on the size of the infant's head?

Cardiovascular System

A newborn's body must make some physiological changes to survive outside the womb. For example, the cardiovascular system must begin to work apart from the maternal circulation. Shortly after birth, the *ductus venosus, ductus arteriosus,* and *foramen ovale* constrict; these structures are unique to the fetal circulation. They close permanently within the first year of life. This results in an increase in systemic vascular resistance. It also results in an increase in aortic, left ventricular, and left atrial pressures. In addition, pulmonary vascular resistance decreases. This occurs because the lungs expand as the baby begins to breathe, which reduces the pulmonary arterial, right ventricular, and right atrial pressures (see Chapters 46 and 47). The left ventricle of the newborn's heart becomes stronger during the first year of life.

Respiratory System

Fetal lungs are filled with fluid. During delivery, the thorax is compressed, and the lung fluid is drained as the newborn gasps for air. Once the newborn gasps, the lung fluid that is left is absorbed through the lymphatic and pulmonary circulations. These strong first breaths open the alveoli and allow subsequent respirations to occur more easily. The principal support for the chest wall comes from muscles rather than bones. These accessory muscles are immature and tire easily. The normal practice of using these muscles for breathing increases the infant's susceptibility to the accumulation of lactic acid in the blood *(lactic acidosis)*. In addition, collateral ventilation between the alveoli and bronchioles is decreased because newborns have fewer alveoli.

NOTE
Infants and small children are "belly breathers." They require full diaphragmatic excursion to produce normal respirations. The use of abdominal muscles to breathe continues until about age 7, when children become more "chest breathers."

A baby's short, narrow airways are less stable than those of adults. Breathing occurs primarily through the nose during the first month of life. With infection or stress, the baby breathes more rapidly and may quickly lose body heat and fluids.

Nervous System

A healthy newborn can respond to a wide variety of stimuli and has a range of *reflexes* (Table 12-1). A number of these reflexes are essential for life outside the womb. These include the reflexes associated with breathing and eating. Other important reflexes are those that result from stress or discomfort. For example, obstruction of the airways may trigger a sneeze or cough. Facial stimulation causes the baby to make sucking movements with the lips **(sucking reflex)** and to turn the head and move the lips toward the touch **(rooting reflex).** Crying may indicate hunger, pain, or discomfort from heat or cold. Some reflexes appear to have no useful purpose and gradually disappear during the first few months of life. These include the **Babinski reflex,** the **Moro reflex,** and the **palmar grasp.**

NOTE
The Babinski reflex is a normal response in infants and young children. However, in an older child or adult, it may indicate damage to the spinal cord (see Chapter 41).

Sleep is thought to be important to normal functioning of the brain. Newborns sleep an average of 16 to 18 hours a day. Sleep and wakefulness are evenly distributed over 24 hours. This sleep pattern gradually decreases to 14 to 16 hours a day with a 9- to 10-hour concentration of sleep at night. By 4 months of age, an infant generally sleeps through the night but can be easily roused.

During the first year of life, a baby makes major advances in physical and mental skills. The brain and nervous system gradually mature during this period. To make room for brain growth, the *posterior fontanelle* (unclosed joint between the bones of the skull) remains open until about 3 months of age. The *anterior fontanelle* remains open for 9 to 18 months after birth. The anterior fontanelle usually is level

TABLE 12-1 Reflexes Associated with Infancy

Reflex	Test	Normal Finding
Babinski	The examiner gently strokes the sole of the infant's foot.	The toes spread outward and upward.
	The examiner presses on the palms of an infant who is lying on the back (supine).	The mouth opens, and the eyes close.
Moro	A loud or startling noise is made near the infant.	The infant stretches the arms and legs, spreads the fingers, and then hugs self.
Palmar grasp	The examiner puts an object or a finger in the infant's palm.	The fingers curl around the object or finger.
Rooting	The examiner gently touches the infant's cheek or an area near the lips.	The infant's head turns toward the stimulation, and the mouth puckers.
Stepping	The examiner holds the infant upright with the feet touching a solid surface.	The infant makes stepping movements that resemble walking.
Sucking	The infant's mouth comes in contact with the nipple of a breast or bottle.	The infant's lips begin to pucker and suck.
Tonic neck	The infant is placed in the supine position.	The infant turns the head and then extends the arm and leg on the side of the body toward which the head is turned.

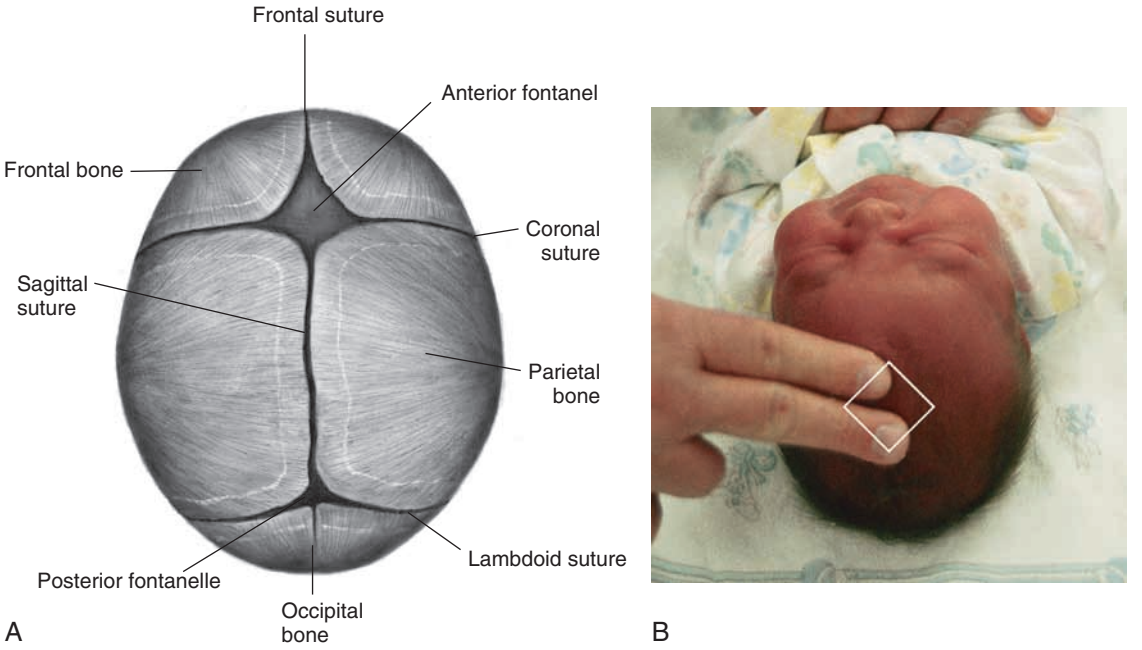

FIGURE 12-2 A, Location of the sutures and fontanelles. **B,** Palpation of the anterior fontanelle. (Price DL, Gwin JF: *Pediatric nursing: an introductory text,* ed 10, St Louis, 2008, Saunders.)

with or slightly below the surface of the skull. It is a good indicator of adequate hydration (with dehydration, the anterior fontanelle may fall below the level of the skull and appear sunken) (Figure 12-2). By the end of the first year, the development of mature nerves is virtually complete. The muscles have matured to the point that many infants can stand and walk with little or no assistance (Figure 12-3).

Musculoskeletal System

At birth the only hard bones are in the fingers. As long bones mature, hormones act on the cartilage in the epiphyses of growing bones. This results in the deposition of calcium salts and the replacement of soft cartilage with hard bone. The *epiphyseal plate* lengthens, and bones thicken as new layers of bone are deposited on existing bone. Factors that influence bone growth include genetics, the production of growth hormone and thyroid hormone, nutrition, and the child's general health status. In infants, muscle weight accounts for about 25% of the entire musculoskeletal system. Motor control in the infant moves from head to toe and from the core to the periphery of the body. Therefore, infants should be able to lift the head before they

are able to sit; also, they can crawl before they are able to walk.[2] The arms and legs are proportionately smaller in the infant. These proportions change throughout the life span (Figure 12-4).

Immune System

Babies are born with enough natural immunity from disease to protect them until they can make their own antibodies. This is known as **passive immunity.** Passive immunity arises from the mother's antibodies, which are passed through the blood to the fetus. If the baby is breastfed, they also are passed through the mother's milk. Passive immunity lasts only about 6 months after birth. After that interval, childhood immunizations against disease (e.g., *pertussis*, *diphtheria*, and *tetanus*) usually are recommended (see Chapter 48).

FIGURE 12-3 Infant. (Courtesy Dustin Sanders, O'Fallon, Mo.)

Metabolism

An infant's metabolic rate is much higher than that of older children or adults. Infants consume more fluids, calories, minerals, and vitamins per pound. They also lose more fluid from the respiratory and integumentary systems than do older children. This predisposes them to dehydration. It also increases the risk of heat- and cold-related illnesses in this age group.[2]

Other Developmental Milestones

Development during infancy depends on the interaction of *heredity* and the *environment*. Growth and development should be compared with standard growth charts showing norms. Box 12-1 lists some developmental milestones from birth to 12 months of age.

Psychosocial Development

The relationship with the caregiver (usually the mother) is a major factor in a baby's psychosocial development. This person is the baby's main source of comfort. The caregiver also represents the baby's main means of coping with stresses in the environment. Such stresses can include fear, pain, and anxiety. Erik Erikson,[3] a proponent of the psychosocial theory, saw human development as the interaction between a person's genes and the environment. He

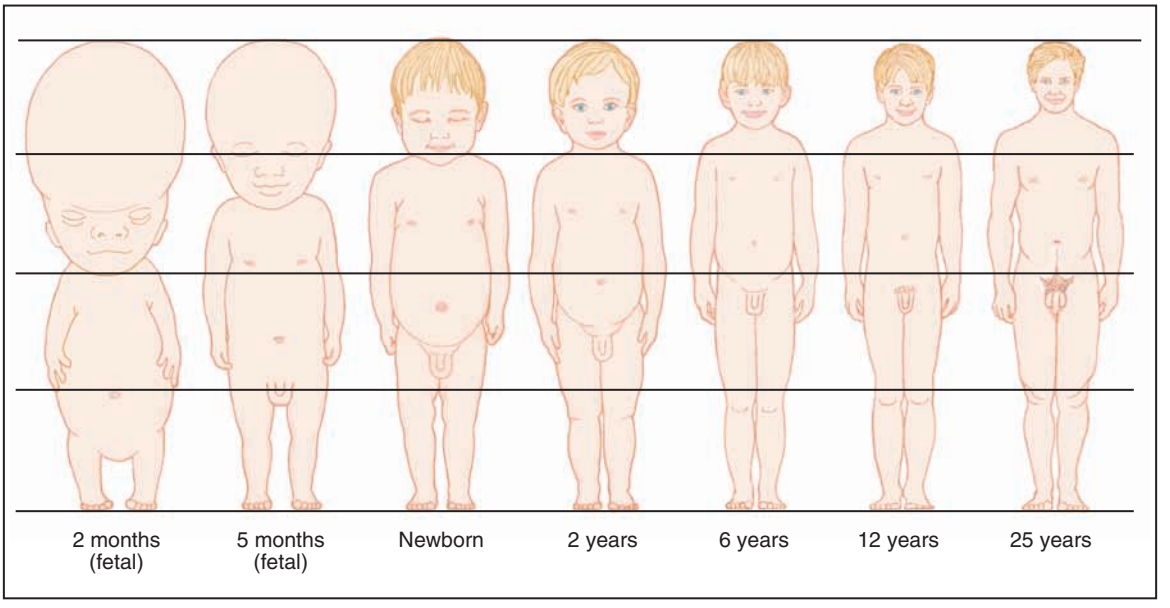

FIGURE 12-4 Changes in body proportions with growth. (McKinney ES et al: *Maternal child nursing,* ed 3, St Louis, 2009, Saunders.)

BOX 12-1 Developmental Milestones (Birth Through 12 Months)

Growth and development should be compared with standard growth charts showing established norms. It is important to remember that infants move through these stages at different rates.

1 Month
- Brings hands within range of eyes and mouth
- Keeps hands in tight fists
- Recognizes some sounds

2 Months
- Tracks objects with eyes
- Recognizes familiar faces

3 Months
- Moves objects to mouth with hands

4 Months
- Drools without swallowing
- Reaches out to people

5 Months
- Sleeps through the night without food
- Gains weight to twice birth weight
- Eruption of teeth may begin

6 Months
- Sits upright in high chair
- Makes one-syllable sounds (ma, mu, da, di)

7 Months
- Fears strangers
- Quickly changes from crying to laughing

8 Months
- Responds to "No"
- Sits without assistance

9 Months
- Responds to adult anger
- Pulls self to standing position
- Explores objects by sucking, chewing, and biting

10 Months
- Recognizes own name
- Crawls well

11 Months
- Attempts to walk unaided
- Shows frustration at restrictions

12 Months
- Walks with assistance
- Gains weight to three times birth weight

theorized that life moves through a series of overlapping stages. Each stage is marked by a crisis that must be resolved. According to Erikson, the most critical stage, which occurs in infancy (up to 1½ years of age), is the trust versus mistrust stage.[3] This stage is based on the infant's knowledge of two things: (1) that the surroundings are safe and predictable and (2) that causes and effects can be anticipated. For example, parental care is warm and loving, but punishment may result from not following rules. Consistency, or lack of it, in this type of care is the basis for trust versus mistrust issues.

TEMPERAMENT

Temperament is a person's style of behavior. It also is the way a person interacts with the environment. Moreover, it is the basis on which children form relationships. Behavioral traits seen in children by 2 to 3 months of age can be used to define three general types of temperament.[4] About 35% of children do not fit any of these categories, but rather demonstrate blends of these characteristics.

- *Easy children.* Easy children are characterized by regularity of bodily functions and low or moderate intensity of reaction. They accept new situations rather than withdraw from them. About 40% of children are easy children.
- *Difficult children.* Difficult children are characterized by irregularity in bodily functions and intense reactions. They withdraw from new situations. Children in this profile have a high activity level and an increased injury risk. About 10% of children are difficult children.
- *Slow-to-warm-up children.* Slow to warm up children are characterized by a low intensity of reaction and a somewhat negative mood. They adjust slowly to new situations. About 15% of children fall into this category.

A child's temperament and the responses this temperament elicits from adults form the basis for *early social interactions*. (Early social interactions are the child's interactions with others and with his or her environment.) This is known as **reciprocal socialization.** A baby's first interactions, combined with developmental changes, lead to specific relationships, as follows[5]:

- During the first few weeks of life, infants are not much affected by an adult's appearance. The only exception is when the infant is fed.
- From about the start of the fourth week, infants begin to direct actions at the adults. Emotional reactions also appear at this time. The baby shows obvious signs of pleasure at the sight and sound of adults, especially females.
- During the second month, more complex and sensitive reactions emerge. These include smiling and vocal sounds aimed at the mother. Animated behavior is shown during interactions.
- By 3 months of age, the infant has formed a need for social interactions. That need continues to grow and

is nourished by adults until the end of the second or the beginning of the third year. At that time, a need for peer interaction develops.

As the infant grows, his or her interactions become more complex. Bonding develops between the infant and family members. These bonds are considered **attachments.** For example, at 4 months of age, an infant shows *perceptual discrimination*. This means the child visually tracks the mother. At 9 months of age, an infant cries when the mother leaves. This is known as **separation anxiety** or *stranger anxiety*.

Separation from true attachments (e.g., separation from a parent) may result in a series of behaviors. The first is *protest* (loud crying, extreme restlessness, and rejection of all adults). Second is *despair* (nonstop crying, inactivity, and withdrawal). Third is *detachment* (a renewed but distant interest in surroundings, even if the mother comes back). Some psychologists believe that attachments continue through a person's life span. When possible, the parent should be allowed to hold the child during the assessment. This accomplishes two goals: first, the child and parent will be less anxious; second, the assessment will be easier to perform if the child is calm and not crying.

TODDLER AND PRESCHOOL YEARS

A child 1 to 3 years of age generally is considered a **toddler.** A child 3 to 5 years of age is considered a **preschooler** (Figure 12-5).

Vital Signs

A toddler's heart rate usually is 80 to 130 bpm. In preschoolers the heart rate is 80 to 100 bpm. Respirations for toddlers and preschoolers average 20 to 30 breaths/minute. A normal systolic blood pressure for toddlers is 70 to 100 mm Hg. For preschoolers it is 80 to 100 mm Hg. The normal body temperature for both age groups is 96.8° to 99.6° F (36° to 37.6° C).

FIGURE 12-5 Preschooler. (Courtesy Kim Robinson, University City, Mo.)

Review of Body Systems

As children enter the toddler and preschool age groups, changes occur in some body systems.

Cardiovascular System. The capillary beds become better developed. They therefore are better able to assist in the body's thermoregulation. Hemoglobin approaches adult levels.

Respiratory System. The ear, nose, and throat structures in toddlers and preschoolers are similar to those in infants. Infants are at greatest risk for serious respiratory illness. Nevertheless, toddlers and preschoolers may acquire such infections in nursery school or preschool. Repeated upper respiratory tract infections may occur. However, they are rarely an indication of underlying disease in toddlers and preschoolers. The use of respiratory muscles changes from primarily abdominal to chest as the child nears school age.

Nervous System. *Myelination* (the maturation of nerve cells) begins in the third trimester and continues for about 10 to 12 years. This eventually provides for a smooth flow of neural impulses throughout the brain, increasing **cognitive development.** Even so, by age 2 much of the nervous system is completely developed. The brain weight is about 90% that of the adult brain. Visual acuity averages 20/30. Hearing essentially is mature by 3 to 4 years of age.

Musculoskeletal System. Muscle mass and bone density increase. Most children walk well with a normal gait by 2 years of age. Fine motor skills (e.g., scribbling with a pencil, stacking building blocks) become evident in toddlers and preschoolers.

Immune System. Passive immunity no longer protects toddlers and preschoolers. They become more susceptible to minor respiratory and gastrointestinal infections.

Endocrine System. The endocrine organs mature and increase production of growth hormone, insulin, and corticosteroid. Children in the toddler and preschool age groups gain an average of 2.9 kg (6½ pounds) a year.

Renal System. The kidneys are well developed by age 2. At this time, many children begin to gain control of bladder and bowel functions. *Specific gravity* is a measure of the concentrating ability of the kidneys. This value and other measurements of urinary function are similar to those in adults (see Chapter 30).

Psychosocial Development

By 2 years of age, children have developed unique personality traits and moods, as well as specific likes and dislikes. Basic language skills are mastered by age 3. Refinement of these skills continues through childhood. Toddlers and preschoolers also begin to recognize the difference between men and women. They begin to model themselves after people of their own gender. Box 12-2 lists other social milestones in the development of toddlers and preschoolers.

BOX 12-2 Social Milestones in Children 1 to 5 Years of Age

1 to 3 Years

- Can combine two different words
- Can complete some word phrases
- Follows directions
- Can point to a named part of the body
- Shows symbolic play when playing with toys
- Can remove some clothing

3 to 5 Years

- Can give first and last name
- Recognizes colors
- Speech is understandable to strangers.
- Completes short sentences and questions
- Can state name of a friend
- Begins to accept temporary absence of primary caregiver
- Plays independently in the presence of other children
- Shows increased level of confidence
- Shows sympathy at appropriate times (e.g., when another child is injured)
- Likes to hear and tell stories

NOTE

Toddlers are active and have a brief attention span. At this age they are at risk for falls, choking, pedestrian/motor vehicle collisions, and burn injuries. Just as with infants, many toddlers do not verbalize feelings of pain or fear directly.[2] Toddlers often have a comfort item, such as a blanket or special toy. When possible, allow the child to hold this during assessment and transport.

CRITICAL THINKING

Reassuring and nonthreatening language should be used when treating toddlers and preschoolers. Consider how a 3-year-old child might interpret statements such as, "I'm going to give you a shot" or "You'll feel a stick in your arm."

TABLE 12-2 Parenting Styles and Associated Traits in Children

Authoritarian Style	Authoritative Style	Permissive Style
Low motivation to achieve	High motivation to achieve	Low motivation to achieve
Low self-esteem	Self-assertiveness	Low self-esteem
Shyness (girls)	Self-reliance	Lack of responsibility
Hostility (boys)	Friendliness, cooperativeness	Aggressiveness

PATTERNS OF PARENTING

Patterns of parenting begin to have an effect on children in the toddler and preschool years (Table 12-2). Most parenting styles fall into one of three categories[6]:

- *Authoritarian*: Authoritarian parents see obedience as a virtue. Conflicts with parents result in the child being punished. Children of authoritarian parents are not given much freedom or independence. Traits seen in these children may include low motivation to achieve, shyness, and hostility. These children also may have low **self-esteem.**
- *Authoritative*: Like authoritarian parents, authoritative parents think that rules must be followed. In this style of parenting, however, the child is given reasons for the rules. The child also is allowed to express a viewpoint, even though the parent has the final say. Authoritative parenting encourages a child to be independent. This style of parenting produces the most successful children. They tend to be responsible, assertive, self-reliant, and have high self-esteem.
- *Permissive:* Permissive parents give their children a lot of freedom. They are tolerant and accepting of the child's behavior, including both aggressive and sexual urges. These parents demand very little from their children. In fact, they tend to view their role as one of helping or serving the child. This style is the opposite of the other two parenting patterns. Traits seen in children raised by permissive parents are similar to those seen in children raised by authoritarian parents. These children are not especially independent, cooperative, or assertive. They often are discontented, distrustful, self-centered, and have low self-esteem.

SIBLING RIVALRY

First-born children often have a special relationship with their parents. They usually are expected to show self-control and responsibility when interacting with younger children. Parents are likely to be stricter with their first-born child, more demanding, and less consistent. They often spend more time with that child than with children who are born later. Because of these and other factors, **sibling rivalry** often becomes evident in the toddler and preschool age groups.

The characteristics of each child are one factor that influences how sibling conflicts occur. For example, a child may be fussy or easily bored or frustrated. A second factor is **family function;** this is the way the family deals with daily problems and conflicts and whether it is done respectfully, productively, and nonaggressively. Sibling rivalry also can be useful in child development. For example, disputes with brothers and sisters can promote crucial skills. These can include learning to value another person's point of view, learning to compromise and negotiate, and learning to control aggressive impulses.

PEER RELATIONSHIPS

Peer relationships offer a source of information about the child's world outside the family. They also expose the child

to other types of families. In the toddler and preschool age groups, peer bonds are formed with others near the same age and maturity. These relationships often begin during play. Play may involve exploring a new toy, acting out fantasies, or using the imagination for new situations. Play also allows children to develop the ability to play simple games and competitive games with rules. This can lead to *problem-solving skills* and cognitive development. Play that involves others fosters interpersonal relationships. Toward the end of the preschool period, children begin to form lasting friendships. The importance of peer bonds and peer-group functions increases throughout childhood.

OTHER FACTORS THAT CAN AFFECT PSYCHOSOCIAL DEVELOPMENT

Two other key factors can have a significant impact on psychosocial development in the toddler and preschool age groups. These factors are *divorce* and *exposure to aggression or violence*.

About half of first marriages in the United States end in divorce.[7] Several factors determine the effect divorce has on toddlers and preschoolers. These include the child's age, cognition, and social competencies, and the child's sense of dependence on or independence from the parents. Children of divorced parents tend to have a higher rate of behavior problems as a result of family conflicts and stress than do children who live in a two-parent home.[8] These problems may arise from a number of factors, including (1) social, economic, and emotional turmoil (including loyalty conflicts); (2) the child's reaction to the loss of the parent who leaves; (3) a change in the custodial parent's behavior toward the child; and (4) the type of day care the child attends as a result of the divorce. Common reactions to divorce in young children include depression, withdrawal, a fear of abandonment, and fear that their parents no longer love them. The parents' ability to recognize and respond to the child's needs is important for helping the child deal with the effects of divorce.

Exposure to violence may increase a child's acceptance of this type of behavior. For example, some children may regularly watch television shows or video games with aggressive overtones. These children may model their behavior on these activities. It is particularly important that parents screen shows and play activities for children in the toddler and preschool age groups.

NOTE

Exposure to alcohol or other drugs also can be a negative factor in a child's behavior. Drug or alcohol abuse in the home environment increases the risk for child abuse. Child abuse is not limited to abuse by parents, but parents account for 80% of offenders.[2] Abuse can be inflicted by babysitters, relatives, domestic partners, or casual acquaintances. Abuse occurs at every socioeconomic level and often is precipitated by a stressful situation in the family (e.g., unemployment, marital problems, chronic illness, poverty).

SCHOOL-AGE YEARS

Children are considered **school age** from 6 to 12 years of age. The heart rate in this age group is 70 to 110 bpm, the respiratory rate is 20 to 30 breaths/minute, the systolic blood pressure is 80 to 120 mm Hg, and the body temperature averages 98.6° F (37° C) (Figure 12-6).

NOTE

School-age children are more independent. Often children of this age begin to play sports. Injuries in school-age children may be related to bicycle or other wheeled activities and to other sports. Failure to wear proper protective equipment often accounts for some of these injuries.

Review of Body Systems

The growth of children in the school-age years is slower and steadier than during infancy and the toddler and preschool years. School-age children gain an average 6.6 cm (2½ inches) in height per year (2.54 centimeters [cm] is equal to 1 inch.) Most bodily functions reach adult levels in this age group. Box 12-3 presents several important developmental milestones for school-age children.

Nervous System. About 95% of the skull's growth is complete by age 10. In addition, children's skills and abilities become more varied as their nervous and musculoskeletal systems develop. Brain function increases in both hemispheres. The child's ability to concentrate and learn develops rapidly in this age group.

Reproductive System. The reproductive system becomes active when a child reaches **puberty.** Puberty is brought about by increasing levels of sex hormones in the body. For

FIGURE 12-6 School-age child. (Courtesy Laura Lamadrid, Hazelwood, Mo.)

BOX 12-3 Developmental Milestones in School-Age Children (6 to 12 Years)

Physical Development

- Weight gain begins to consist more of muscle than fat; physical strength increases.
- Psychomotor skills (e.g., throwing, jumping, running) improve.
- Boys experience a "growth spurt" around age 12.
- Body changes indicate approaching puberty.
- Proportions of face and body become closer to those of adults.
- Eyes reach maturity in size and function.
- Permanent teeth begin to develop.
- Right- or left-handedness becomes well established.

Cognitive, Social, and Emotional Development

- Child is permitted more self-regulation with less supervision in the family setting.
- Parents usually spend less time with the child.
- Child's moral reasoning capabilities develop.
- Child gradually gains an understanding of the concept of death.
- Sexual interest grows rapidly with onset of puberty.
- Friendships become based on loyalty and mutual support.
- Social skills of giving, receiving, and sharing are learned.

both genders, these hormone levels begin increasing before any external signs appear. The timing of puberty varies greatly. On average, it starts 2 years earlier in girls (between ages 8 and 13) than in boys (between ages 13 and 15).

Lymphatic System. The lymphatic system plays a key role in fighting disease and infection. This system undergoes many changes throughout a child's growth until puberty, when growth slows. Until that time, the lymphatic tissues in school-age children are proportionally larger than in adults.

Psychosocial Development

Between the ages of 6 and 12, the child's world expands outward from the family. At this time, relationships are formed with friends, teachers, coaches, caregivers, and others. As interactions with others increase, the school-age child begins to compare himself or herself with others, thus developing a **self-concept.** Some situations can create stress and affect self-esteem. Self-esteem is often based on external factors (e.g., popularity with peers, experience of rejection, emotional support from family and friends). It seems to be higher in the early years of school age. Low self-esteem can have damaging effects in later development.

Psychosocial development varies by individual. Some children seem very *mature*. Others seem very *immature*. During this stage, behavior may depend on the child's mood and experience with various types of people. It may even be determined simply by what happened on a certain day. In addition, school-age children begin to face the normal challenges of daily life. Fear of new situations (e.g., attending school) and peer pressure are predictable stressors for this age group.

Moral development occurs over time through experience. For school-age children, control of behavior begins to shift from external sources (e.g., what parents believe is right or wrong) to more internal self-control. With this internal control, these children justify the morality of their choices.

Many theories attempt to explain moral development. Kohlberg's theory proposes six stages, extending from about 4 years of age through adulthood. The stages occur at three age-related levels of development: preconventional reasoning, conventional reasoning, and postconventional reasoning[9] (Box 12-4). Most experts agree that loving, caring, and positive bonds play key roles in moral education.

SHOW ME THE EVIDENCE

Researchers in England weighed children between the ages of 1 and 10 years to test the accuracy of a shortcut for evaluating weight in children [i.e., 2(Age + 4) = Weight (kg)]. According to the study, this weight formula underestimated the weight of children by a mean of 18.8% (confidence interval, 95%). The authors found that the most accurate formula for their population of children was 3(Age + 7) = Weight (kg).

Luscombe M, Owens B: Weight estimation in resuscitation: Is the current formula still valid? *Arch Dis Child* 92:412-415, 2007.

ADOLESCENCE

An individual 13 to 19 years of age is an **adolescent** (Figure 12-7). Normal vital signs for this age group are a heart rate of 55 to 105 bpm, respirations of 12 to 20 breaths/minute, a systolic blood pressure of 100 to 120 mm Hg, and a body temperature of 98.6° F (37° C). Adolescence is the final phase of change in growth and development. Organs rapidly increase in size, including the heart, kidneys, spleen, and liver. Blood chemistry values are nearly the same as those in adults (see Chapter 32). Activity of the sebaceous glands causes the skin to toughen. Growth of bone and muscle mass is nearly completed during the 2- to 3-year adolescent growth spurt.

During adolescence an individual reaches **reproductive maturity.** In girls, the first external sign of puberty is a change in one or both nipples. The nipples change into what is known as a *breast bud*. A few months later, pubic hair and underarm hair begin to grow, and the breasts enlarge. Within about 2 years after the appearance of the breast bud and after body fat reaches 18% to 20% of body weight, **menarche** (first menstruation) usually occurs. Changes in the endocrine system cause the release of *gonadotropin, luteinizing hormone,* and *follicle-stimulating hormone*. These hormonal substances promote estrogen and

BOX 12-4 Kohlberg's Stages of Moral Development

Preconventional Reasoning (About 4 to 10 Years)

From 4 to 10 years of age, children respond to cultural control mainly to avoid punishment and attain satisfaction. The first two stages occur at this level:

- Stage 1—Punishment and obedience: Children obey rules and orders to avoid punishment; the child has no concern about moral rectitude.
- Stage 2—Naïve instrumental behaviorism: Children obey rules but only out of pure self-interest. They are vaguely aware of fairness to others but only for their own satisfaction. The concept of *reciprocity* comes into play (i.e., "You scratch my back, I'll scratch yours.")

Conventional Reasoning (About 10 to 13 Years)

From 10 to 13 years of age, children desire approval both from individuals and society. They not only conform, they actively seek to support society's standards. The next two stages occur at this level:

- Stage 3—Good boy/good girl mentality: Children seek the approval of others. They begin to judge behavior by intention (e.g., "She meant to do well.")
- Stage 4—Law and order mentality: Children are concerned with authority and with maintaining the social order. Correct behavior is "doing one's duty."

Postconventional Reasoning (13 Years and Older)

If true morality (an internal moral code) is to develop, it appears during these years. The person does not appeal to other people for moral decisions. Such decisions are made by an "enlightened conscience." The final two stages occur at this level:

- Stage 5—The person makes moral decisions legalistically or contractually: This means that the best values are those supported by law, because they have been accepted by society as a whole. If a conflict arises between human need and the law, people work to change the law.
- Stage 6—An informed conscience defines what is right: An individual's actions are not based on fear, a need for approval, or legal demands, but on the person's own internalized standards of right and wrong.

Modified from Kohlberg L: A cognitive-developmental analysis of children's sex-role concepts and attitudes. In MacCoby E, editor: *The development of sex differences,* Stanford, Calif, 1996, Stanford University Press.

progesterone production. Progesterone affects breast development and the menstrual cycle. Estrogen causes the development of the female secondary sex characteristics, such as disposition of subcutaneous fat in the breast, thighs, and buttocks and the development of axial and pubic hair. Estrogen also promotes the buildup of endometrium in the uterus.

FIGURE 12-7 Adolescent. (Courtesy Laura Lamadrid, Hazelwood, Mo.)

NOTE

Teen pregnancy is also known as adolescent pregnancy. Although most teenagers do not plan to become pregnant, some do. Teen pregnancies carry extra health risks for the mother and the baby. Teenagers often do not receive timely prenatal care, and they have a higher risk for pregnancy-related high blood pressure and its complications. Risks for the baby include premature birth and a low birth weight.[10]

In boys, gonadotropin promotes testosterone production. Testosterone is a hormone produced by the testes. It causes the development of the male secondary sex characteristics. These include color and texture changes in the scrotum and an increase in the size of the testes. With these changes, the penis begins to enlarge and assume an adult shape, and pubic hair grows. At about age 14, a boy's first ejaculation of semen occurs during **masturbation** or sleep. Other male secondary sex characteristics that occur during late adolescence and early adulthood include deepening of the voice, facial hair, underarm hair, and sometimes the growth of chest hair.

The development of secondary sex characteristics in both genders coincides with the last period of rapid growth in adolescence. Rapid growth usually is preceded by an increase in body fat. This body fat decreases during the period of growth and increases again in later years. Girls retain more fat than boys in the subcutaneous tissue in the areas of the breasts, thighs, and buttocks. Boys gain an average of 20 cm (8 inches) in height before age 21, when growth usually stops. Growth in girls is less dramatic. It usually is complete by age 18. During the period of rapid growth in adolescence, the hands and feet grow first. The arms and legs then begin to lengthen, and the shoulders

become broader. Finally, the trunk of the body grows. The bones of the upper and lower jaw also grow. As a result, the face can change dramatically in appearance within a short time, especially in boys.

Psychosocial Development

In addition to physical changes, adolescence usually involves some emotional turmoil (Box 12-5). Adolescents may "try on" identities. These young people also begin to develop their adult personality. Conflicts with parents over school, manners, dress, hygiene, curfews, and other topics are common, because the adolescent has begun to express independence. As a result of these conflicts, most adolescents draw away from their parents. At the same time, they may emotionally move more toward their peers. Friendships with others who are also trying on various identities may result in the use of alcohol and other drugs, sexual experimentation, and extreme forms of behavior or dress. Antisocial behavior tends to peak at about the eighth- or ninth-grade level.

In the teenage years, both boys and girls are very concerned about their appearance. Comparisons continually are made among peers. Concerns about body image are common in this age group. These include weight issues, body odor, acne, and dandruff. All these conditions can arise from the hormonal changes associated with adolescence. During adolescence many teenagers, especially girls, become obsessed with weight loss. They may try fad diets to control their figures. Eating disorders are common in this age group. Obsession with weight loss may lead to bulimia, anorexia nervosa, and severe depression. In fact, depression and suicide are more common among adolescents than in any other age group.[1]

BOX 12-5 Psychosocial Development of Adolescents (13 to 18 Years)

Some variations from the following descriptions are to be expected. Also, some characteristics and traits may be affected by other developmental issues.

13 to 14 Years
- Struggles with identity issues
- Displays moodiness
- Develops close friendships
- Pays less attention to parents
- Interests and clothing styles are influenced by peer groups.
- Shows ability to work
- Has same-sex friends
- Develops need for privacy
- Experiments with body (masturbation)
- May experiment with cigarettes, alcohol, and marijuana
- Has capacity for abstract thought

14 to 17 Years
- Becomes self-involved
- Shows extreme concern with body image and sexual attractiveness
- Examines personal and inner experiences
- Channels sexual and aggressive energies into creative activities (e.g., poetry, writing, music)
- Develops feelings of sexual love and passion
- Selects role models
- Shows greater capacity for setting goals

17 to 18 Years
- Develops secure personal identity
- Shows greater emotional stability
- Has heightened sense of humor
- Shows pride in work
- Shows stable interests and concern for others
- Has higher level of concern for the future
- Develops clear sexual identity and ability for sensual love
- Shows gradual interest in adult behavior
- Accepts social norms and cultural traditions
- Can set goals and follow through with plans

CRITICAL THINKING

It may be best to interview the adolescent and the parents separately. Why might this be important?

NOTE

Learning to drive an automobile occurs during adolescence. Motor vehicle collisions represent the top cause of death in children of this age. Homicide is now the second-leading cause of death in adolescents in the United States, and suicide is third. According to the Centers for Disease Control and Prevention (CDC), most of these homicides and about one half of the suicides involve a firearm.[11]

EARLY ADULTHOOD

Early adulthood spans the period from 20 to 40 years of age (Figure 12-8). Average vital signs for this age group are a heart rate of 70 bpm, respirations of 16 to 20 breaths/minute, a blood pressure of 120/80 mm Hg, and a body temperature of 98.6° F (37° C). At the onset of early adulthood, individuals are reaching their physical peak. This is achieved between 19 and 26 years of age. Lifelong habits and routines develop. Body systems are at their optimum performance. This also is the age group in which pregnancy is most likely to occur. However, the aging process has begun. Some of the effects of aging (e.g., slowed reaction times, hearing loss, vision deficiencies) gradually become evident during this stage of life. Good health in early adulthood tends to be centered on lifestyle and physical fitness. Unintentional injury is the leading cause of death in this age group.

Psychosocial Development

The ability to love usually is well developed by early adulthood. This includes both romantic and affectionate love. Also, newly formed families bring on new challenges and

FIGURE 12-8 Early adulthood. (Courtesy Chad Sanders, Wentzville, Mo.)

FIGURE 12-9 Middle adulthood. (Courtesy Norma Boozer, Florissant, Mo.)

stresses during this period. The highest levels of job stress are felt in this age group. Even so, fewer psychological issues related to well-being arise during early adulthood than during any other phase of life. Most individuals in this age group focus their attention on career and family as part of their psychosocial development. Their pursuits include the following:

- Selecting a mate
- Learning to live with a marriage partner
- Raising children
- Managing a home
- Finding a congenial social group
- Developing adult leisure time activities
- Selecting a secure and stable occupation
- Establishing and maintaining an economic standard of living

MIDDLE ADULTHOOD

Middle adulthood extends from 41 to 60 years of age (Figure 12-9). The average vital signs are the same as for early adulthood. Also, body systems continue to work at a high level. However, the physiological aspects of aging may become more obvious during this stage. For example, cardiovascular health becomes a concern. Hearing and vision changes occur. **Periodontal disease** may develop. Weight control becomes more difficult. Cancer tends to strike often. For women, **menopause** normally occurs between age 45 and 55. This marks the end of reproductive capacity.

Psychosocial Development

Middle adulthood generally is a productive time for social and professional recognition. It often is a period of financial security. However, because of the physical changes just described, the person in middle adulthood often becomes concerned with the "social clock." The individual may feel a sense of time pressure to meet lifelong goals. Common causes of stress in this age group include financial commitments and responsibility for the care of elderly parents. Another stress is concern for young adult children who have moved out and are on their own. As the last child leaves home, a depression or sense of loss is not unusual for many parents *(empty nest syndrome)*. Others feel a sense of freedom and enjoy a greater chance for self-fulfillment.

Some adults in middle age experience a "midlife crisis." They may make sudden and sometimes irrational changes in their life (similar to the identity issues seen in the teenage years). This may occur because of health worries, a change in physical appearance as a result of aging, or a change in the level of sexual activity with a spouse. However, most middle-aged adults tend to approach problems in their lives more as challenges than as threats. Important goals, for example, often are (1) to help their children to be responsible and happy adults; (2) to accept and adjust to aging parents; and (3) to accept the physiological changes of middle age.

LATE ADULTHOOD

People reach **late adulthood** at 61 years of age (Figure 12-10). Vital signs in this age group depend on the individual's health status. Moreover, they are affected by the physiological changes in body systems that normally occur during this stage of life. A person's life span is determined by health, genetics, and other factors. The theoretical maximum life span for human beings is 120 years.[1]

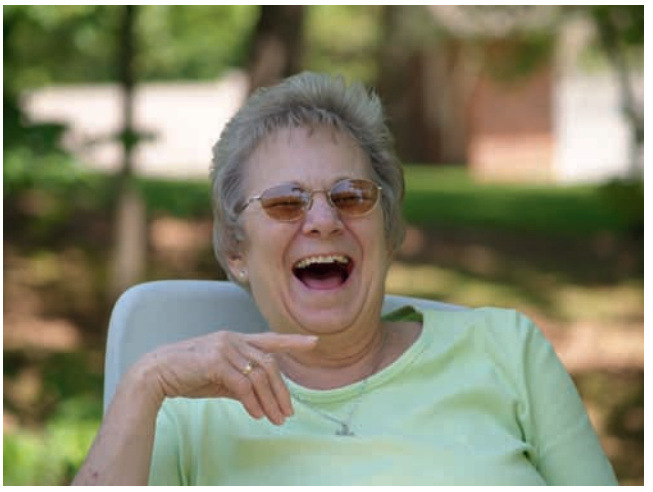

FIGURE 12-10 Late adulthood. (Courtesy Shirley Bohnert, St. Charles, Mo.)

DID YOU KNOW?

According to *The State of Aging and Health in America 2004*, 70 million Americans—1 in 5—will be 65 or older by 2030. The fastest growing segment of the older population is elders age 85 or older. This segment is expected to double, from 5 million in 2003 to 10 million by 2030, and then to double again to 20 million by 2050.[12]

Review of Body Systems

Body system changes associated with late adulthood vary from person to person (Figure 12-11 and Box 12-6). They also vary from organ to organ and from function to function (see Chapter 49). Some occur dramatically. Others occur gradually. Some functions even remain constant well into old age. This variation can be seen in a number of systems. For example, a decrease in cardiac output and the ability to metabolize carbohydrates becomes evident early on. Changes in skin texture and hair color occur throughout late adulthood. The speed of nerve conduction and the manufacture of red blood cells do not decline until late old age.

SHOW ME THE EVIDENCE

Jacobs and colleagues reviewed current trauma literature to try to discover the reasons older adults have higher mortality and poorer outcomes after injury. Although they did not identify any clear cause for this poor prognosis, they noted that elderly patients who received prompt treatment at a trauma center had better outcomes. They also pointed out that undertriage of injured patients in this age group was a problem. The authors noted the need for more well-designed prospective research in this area.

From Jacobs D: Special considerations in geriatric injury, *Curr Opin Crit Care* 9:535-539, 2003.

Psychosocial Development

Society's attitude toward age can either enhance or detract from an older person's sense of self-worth. Some cultures credit wisdom to age; others consider the elderly to be more of a burden. For those who enjoy good health and retirement, late adulthood is a time of happiness and personal fulfillment. For others, this period is marked by financial burdens and physical and emotional challenges.

FINANCIAL BURDENS

Most people in late age begin to accept and adjust to retirement. They also adjust to having a reduced income. However, they face new issues. For example, some must pay for health care, and they may need to establish new living arrangements. About 95% of older adults live in their homes. These individuals choose not to reside in home care facilities such as nursing homes and assisted care communities. The financial requirements for either type of living arrangement can be a burden for the older adult and the family. For example, an older person living at home may require in-home health and home care services to assist with tasks of daily living. An older person who lives in a home care facility may need constant nursing care and other types of supervision. These situations, plus the cost of health insurance, prescription medicines, and other health care needs, can create financial burdens, even for those who plan well for their retirement. In 2007, about 3.6 million older adults in the United States were living below the poverty level, and more than 2 million were considered to be near-poor.[13]

CRITICAL THINKING

In an older patient's home, what clues may indicate that the person is under a financial strain or burden?

PHYSICAL AND EMOTIONAL CHALLENGES

In addition to the physical challenges linked to aging and the related health consequences, older adults face emotional challenges. Two emotional dilemmas are commonly faced in advancing years. One is accepting a decline in cognition. The other is dealing with the dying or death of a companion.

Aging does not always produce a decline in brain function. However, some conditions can cause a loss of mental faculties. Such conditions include circulatory disorders and some diseases common in older adults (e.g., *Parkinson's disease*). Problems with short-term memory, learning, attention, and judgment may develop. This decline in mental capability is an important concern and a cause of depression in older adults.

Terminal drop refers to the theory that a decline in intelligence in later years may be caused by a person's

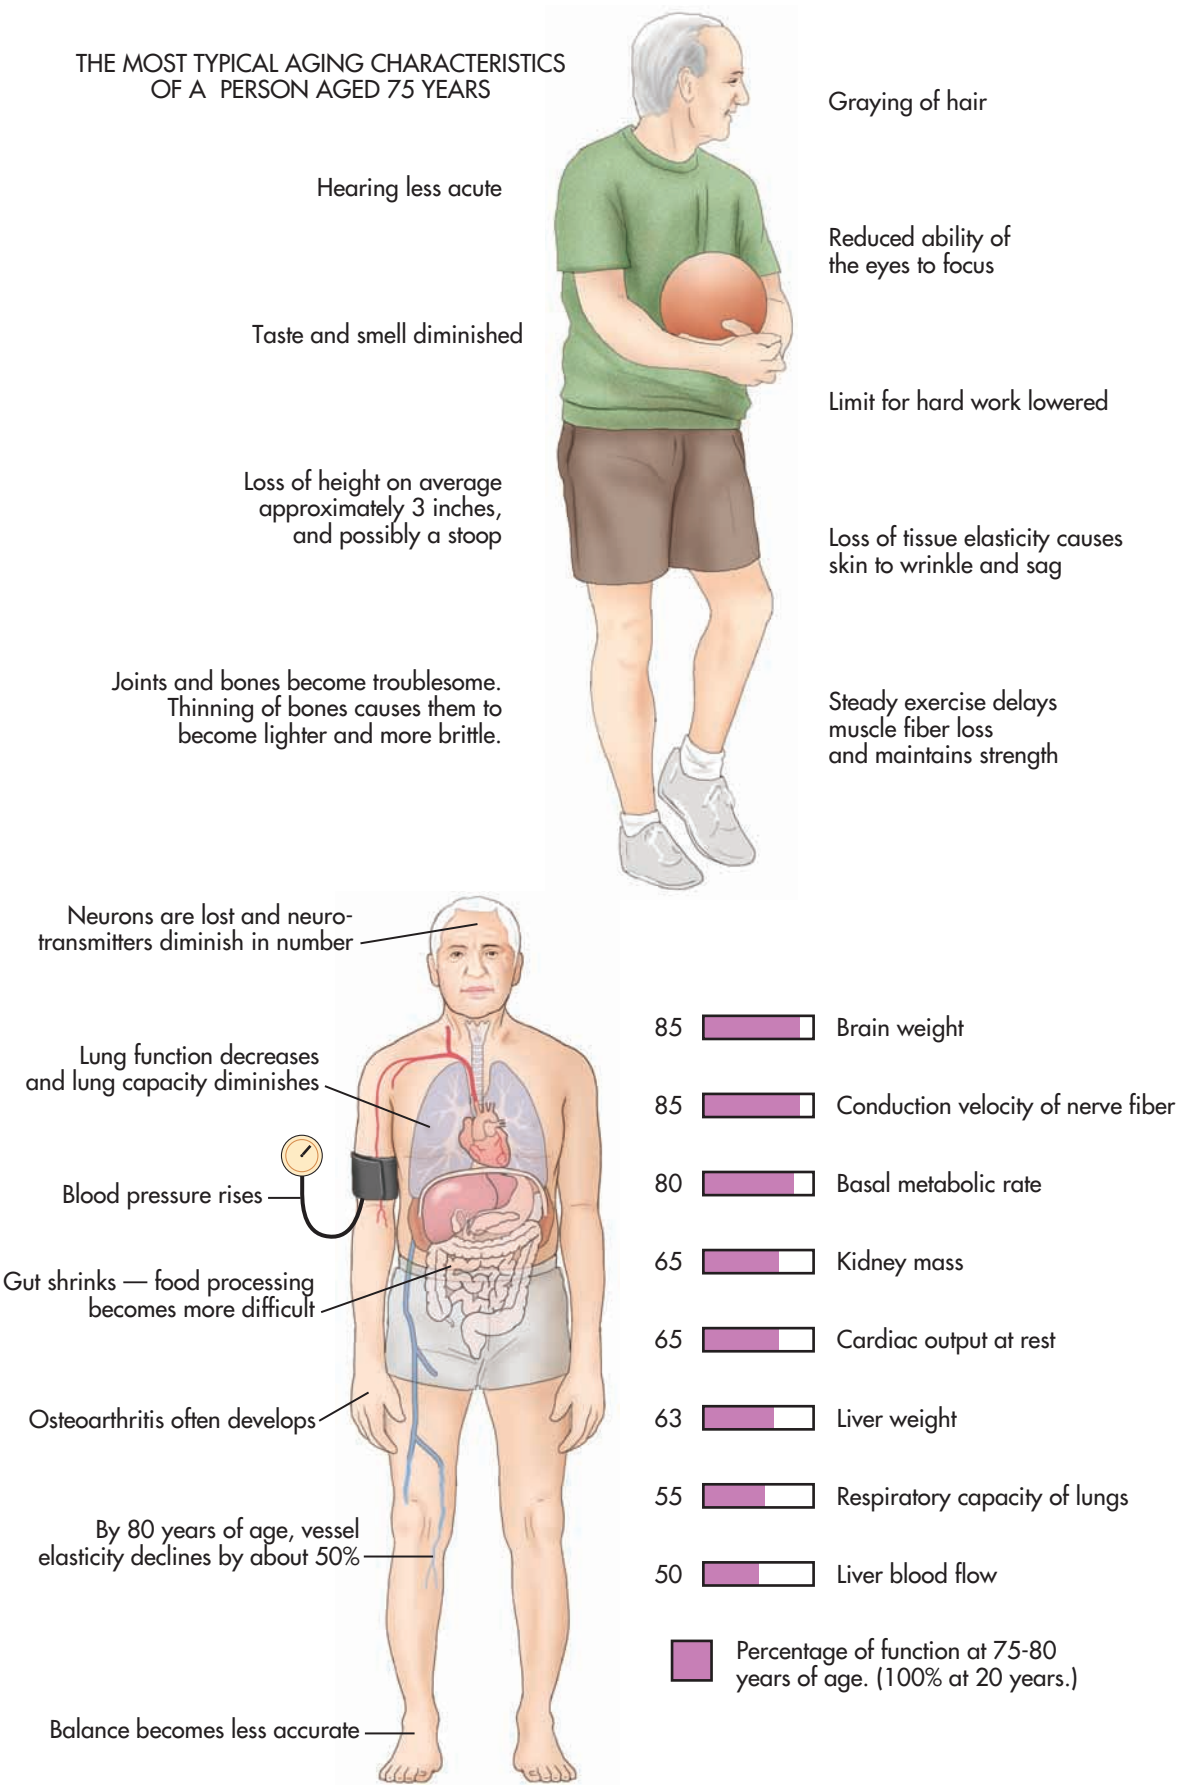

FIGURE 12-11 Body changes that occur in late adulthood.

BOX 12-6 Physiological Changes Associated With Late Adulthood

Cardiovascular System
- Functional changes occur as blood vessels thicken and peripheral resistance increases.
- By 80 years of age, vessel elasticity declines by about 50%.
- Blood flow to organs decreases.
- Baroreceptor sensitivity is reduced, and blood pressure tends to rise.
- Increased workload of the heart causes cardiomegaly, changes in the mitral and aortic valves, and decreased myocardial elasticity.
- The heart becomes less able to respond to exercise.
- The number of pacemaker cells in the heart diminishes, resulting in dysrhythmias (tachycardias are not well tolerated).
- The functional blood volume and platelet count decrease.
- The number of red blood cells decreases in late old age.
- Iron levels are poor.

Respiratory System
- Functional changes occur in the mouth, nose, and lungs.
- Lung function decreases, and lung capacity diminishes.
- The elasticity of the diaphragm declines, and the chest wall weakens.
- Diffusion through the alveoli diminishes from lifelong exposure to pollutants.
- Less oxygen becomes available for uptake by the blood.
- Coughing becomes ineffective because of weakened chest wall function and bone structure.

Nervous System
- Neurons are lost, and neurotransmitters diminish in number.
- Some taste buds are lost, and the olfactory sense diminishes.
- Pain perception decreases.
- The kinesthetic sense (sense of body movement) is lessened.
- Visual acuity diminishes.
- Reaction time declines.
- Hearing changes occur.
- The sleep-wake cycle is disrupted.

Musculoskeletal System
- Muscle mass is replaced by fibrous tissue.
- Progressive bone loss occurs, and changes in bones and joints become troublesome.
- Balance becomes less accurate.
- Osteoarthritis often develops.
- Shrinking of vertebral disks leads to loss of height and stooping posture.

Gastrointestinal System
- Secretion of saliva and gastric juices is reduced.
- Peristalsis and gastrointestinal secretions decrease.
- The esophageal sphincter becomes less effective, and internal intestinal sphincters lose tone.
- Vitamin and mineral deficiencies occur.
- Changes in the liver affect the metabolism of some drugs and foods.

Endocrine System
- Glucose metabolism and the production of insulin decrease.
- Production of triiodothyronine (T_3) by the thyroid gland declines.
- Production of cortisol decreases by about 25%.
- The pituitary gland becomes about 20% less effective.
- Women's reproductive glands begin to atrophy.

Renal System
- About 50% of the nephrons in the kidneys are lost.
- The filtration surface in the kidneys is reduced.
- Salt and water balance is compromised.
- Abnormal glomeruli become more common.
- The frequency of urination and the amount of urine eliminated decrease.

conscious or unconscious perception of coming death.[8] (This decline is measured by a change in IQ test results.) Such a perception may cause the person to begin withdrawing from the world anywhere from a few weeks up to 5 years before death. Terminal drop may become evident by changes in mood or mental functioning or by the way the body responds. It also may be linked to the presence of a disease (e.g., cancer). According to the terminal drop theory, the higher a person's IQ in old age, the longer the person is likely to live after the IQ test.

The dying or death of a partner can be one of the most stressful events in life. The ways in which a person deals with the death or imminent death of a partner are based on a number of factors. These include the person's cultural or religious views, the cause and timing of death, the length and type of relationship, the person's quality of life before death, and the support of friends, family, and organizations. Most people experience a variety of emotions in dealing with death and dying. These range from initial denial to final acceptance (see Chapter 2).

SUMMARY

- A newborn is a baby in the first hours of life. A neonate is a baby younger than 28 days. An infant is a child 28 days to 1 year of age.
- The newborn normally weighs 3 to 3.5 kg (7 to 8 pounds). This weight typically triples in 9 to 12 months. The infant's head accounts for about 25% of the total body weight.
- At birth, structures unique to fetal circulation constrict and normally close within the first year of life. Fluid is expelled from the lungs during the first few breaths.

Respiratory muscles and alveoli are not fully developed.
- Infants are born with protective reflexes related to breathing, eating, and stress or discomfort.
- At birth the anterior and posterior fontanels are open. Bone growth occurs at the epiphysis of the bones.
- Some passive immunity is conferred at birth and through the mother's breast milk.
- The caregiver is the major factor in the infant's psychosocial development.
- Temperament is a person's behavioral style. It is the way the person interacts with the environment.
- Toddlers are children 1 to 3 years of age. Preschoolers are children 3 to 5 years of age.
- The hemoglobin level in toddlers and preschoolers approaches that of adults. The brain in this age group is about 90% of the adult brain weight. Muscle mass and bone density increase. Walking occurs by age 2, and fine motor skills develop. Control of bowel and bladder are achieved.
- Parenting styles can be described as authoritarian, authoritative, or permissive.
- Sibling rivalry, peer relationships, divorce, and exposure to aggression and violence affect a child's development.
- School-age children range from 6 to 12 years of age. Physical growth slows, but brain function and the ability to learn quickly develop in this age group. Many children reach puberty during this time. Self-esteem and moral development are critical at this age.
- Adolescents are 13 to 19 years of age. The growth of bone and muscle mass is nearly complete in this age group. Reproductive maturity has been reached. Adolescence often involves some emotional turmoil, and antisocial behavior may be seen.
- Early adulthood spans the period from 20 to 40 years of age. Lifelong habits and routines develop. Body systems are at their optimal performance.
- Middle adulthood extends from 41 to 60 years of age. The physiological aspects of aging become more apparent in this age group. Menopause in women occurs during this stage.
- People reach late adulthood at 61 years of age. Body system changes vary widely from person to person, but the systemic changes of aging become apparent. Some adults in this age group face financial, physical, and emotional challenges.

PART THREE

Pharmacology

Chapter 13 Principles of Pharmacology and Emergency Medications

Chapter 14 Venous Access and Medication Administration

CHAPTER

13 Principles of Pharmacology and Emergency Medications

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Define the term "drug."
2. Identify the four types of drug names.
3. Outline drug standards and legislation and the enforcement agencies pertinent to the paramedic profession.
4. Distinguish between characteristics of routes of drug administration.
5. Discuss factors that influence drug absorption, distribution, and elimination.
6. Describe how drugs react with receptors to produce their desired effects.
7. List variables that can influence drug interactions.
8. Distinguish among drug forms.
9. Describe the paramedic's responsibilities to understand drug profiles.
10. Identify special considerations for administering pharmacological agents to pregnant patients, pediatric patients, and older patients.
11. Outline drug actions and care considerations for a patient who is given drugs that affect the nervous, cardiovascular, respiratory, endocrine, and gastrointestinal systems.
12. Explain the meaning of drug terms that are necessary to interpret information in drug references safely.

KEY TERMS

absorption The process by which drug molecules are moved from the site of entry into the body into the general circulation.

acetylcholine A neurotransmitter, widely distributed in body tissues, with the primary function of mediating the synaptic activity of the nervous system.

adrenergic Of or pertaining to the sympathetic nerve fibers of the autonomic nervous system, which use epinephrine or epinephrine-like substances as neurotransmitters.

agonists Drugs that combine with receptors and initiate the expected response.

alpha-adrenergic receptor Any one of the postulated adrenergic components of receptor tissues that responds to norepinephrine and to various blocking agents.

antagonists Agents designed to inhibit or counteract the effects of other drugs or undesired effects caused by normal or hyperactive physiological mechanisms.

anticholinergic Of or pertaining to the blocking of acetylcholine receptors, resulting in inhibition of transmission of parasympathetic nerve impulses.

beta-adrenergic receptor Any of the postulated adrenergic components of receptor tissues that respond to epinephrine and various blocking agents.

biological half-life The time required to metabolize or eliminate half the total amount of a drug in the body.

biotransformation The process by which a drug is converted chemically to a metabolite.

blood-brain barrier An anatomical-physiological feature of the brain thought to consist of walls of capillaries in the central nervous system and surrounding glial membranes; its function is to prevent or slow the passage of chemical compounds from the blood into the central nervous system.

blood coagulation A process that results in the formation of a stable fibrin clot that entraps platelets, blood cells, and plasma.

chemical name The exact designation of a chemical structure as determined by the rules of chemical nomenclature.

cholinergic Of or pertaining to the effects produced by the parasympathetic nervous system or drugs that stimulate or antagonize the parasympathetic nervous system.

contraindications Medical or physiological factors that make it harmful to administer a medication that would otherwise have a therapeutic effect.

controlled substance Any drug defined in the categories of the Comprehensive Drug Abuse Prevention and Control Act (also known as the Controlled Substances Act) of 1970.

cumulative action The effect that occurs when several doses of a drug are administered or when absorption occurs more quickly than removal by excretion or metabolism or both.

distribution The transport of a drug through the bloodstream to various tissues of the body and ultimately to its site of action.

drug Any substance taken by mouth; injected into a muscle, blood vessel, or cavity of the body; or applied topically to treat or prevent a disease or condition.

drug interaction Modification of the effects of one drug by the previous or concurrent administration of another drug, thereby increasing or diminishing the pharmacological or physiological action of one or both drugs.

drug-protein complex A complex formed by the attachment of a drug to proteins, mainly albumin.

drug receptors Parts of a cell (usually an enzyme or large protein molecule) with which a drug molecule interacts to trigger its desired response or effect.

dystonia A condition characterized by local or diffuse changes in muscle tone, resulting in painful muscle spasms, unusually fixed postures, and strange movement patterns.

effective dose 50 (ED_{50}) The amount of drug that produces a therapeutic response in 50% of those who take it.

effector organ A muscle or gland that responds to nerve impulses from the central nervous system.

endorphin Any of several peptides secreted in the brain that have a pain-relieving effect like morphine.

excretion The elimination of toxic or inactive metabolites, primarily by the kidneys; the intestines, lungs, and mammary, sweat, and salivary glands also may be involved.

first-pass metabolism The initial biotransformation of a drug during passage through the liver from the portal vein that occurs before the drug reaches the general circulation.

generic name The official, established name assigned to a drug.

idiopathic Arising from an obscure or unknown cause.

idiosyncrasy An abnormal or peculiar response to a drug.

loading dose A large quantity of drug that temporarily exceeds the capacity of the body to excrete the drug.

maintenance dose The amount of a drug required to keep a desired steady state of drug concentration in tissues.

neurotransmitter A chemical that is released from one neuron at the presynaptic nerve fiber.

nonselective beta-blocking agents Agents that block $beta_1$- and $beta_2$-receptor sites.

official name The name of a drug that is followed by the initials USP (*United States Pharmacopeia*) or NF (*National Formulary*), denoting its listing in one of the official publications; usually the same as the generic name.

orphan drug A medication that has been developed specifically to treat a rare medical condition.

parenteral Of or pertaining to any medication route other than the alimentary canal.

partial reabsorption The reabsorption from the renal tubule by passive diffusion.

pharmaceutics The science of dispensing drugs.

pharmacodynamics The study of how a drug acts on a living organism.

pharmacokinetics The study of how the body handles a drug over a period of time, including the processes of absorption, distribution, biotransformation, and excretion.

placebo An inactive substance or a less than effective dose of a harmless substance; it is used in experimental drug studies to compare the effects of the inactive substance with those of the experimental drug.

placental barrier A protective biological membrane that separates the blood vessels of the mother and the fetus.

potentiation Enhancement of the effect of a drug, caused by concurrent administration of two drugs in which one drug increases the effect of the other.

selective beta-blocking agents Agents block $beta_1$ or $beta_2$ receptors.

summation The combined effects of two drugs that equal the sum of the individual effects of each agent.

synergism The combined action of two drugs that is greater than the sum of each agent acting independently.

tardive dyskinesia A potentially irreversible neurological disorder characterized by involuntary repetitious movements of the muscles of the face, limbs, and trunk.

therapeutic action The desired, intended action of a drug.

therapeutic index A measurement of the relative safety of a drug.

therapeutic range The range of plasma concentrations that is most likely to produce the desired drug effect with the least likelihood of toxicity; the range between minimal effective concentration and toxic level.

tolerance A physiological response that requires that a drug dosage be increased to produce the same effect formerly produced by a smaller dose.

trade name The trademark name of a drug, designated by the drug company that sells the medication.

untoward effects Side effects that prove harmful to the patient.

Pharmacology can be defined as the science of drugs used to prevent, diagnose, and treat disease. Pharmacology deals with the interactions between living systems and chemical molecules. The paramedic must have a thorough understanding of a drug and its actions before it is administered. This understanding will help to ensure maximum effectiveness and will reduce the potential for harm.

NOTE

This chapter introduces the paramedic to general principles of pharmacology and emergency medications commonly used in the prehospital setting. A more complete description of the emergency drugs discussed in this chapter can be found in the Emergency Drug Index. Medications described in this text that are included in the index are denoted by boldface italic type

The drug information presented in this section conforms to current medical literature, to manufacturers' monographs, and to the clinical practice of the general medical community at the time of publication. Although every effort has been made to ensure accuracy and completeness, the authors, editors, medical advisers, and publisher disclaim liability for any discrepancies, incongruities, undetected errors, omissions in content, or reader misunderstanding. Local protocol for drug administration may vary from the information presented in this chapter. The paramedic should follow the guidelines established by medical direction.

SECTION ONE
Drug Information

HISTORICAL TRENDS IN PHARMACOLOGY

The science of pharmacology may date back as early as 10,000 to 7000 BC.[1] Medicinal herbs are thought to have been among the plants grown by human beings in the Neolithic period. Yet whether the herbs were thought to have healing properties is not known. A number of medicines are mentioned in the Bible. Some of these include gums, spices, oils, and maybe even narcotics. Drugs derived from plants were used heavily throughout the Middle Ages. They were used as digestives, laxatives, and diuretics (Figure 13-1).

The concept of "chemical medicine" was born in the seventeenth century. Some preparations introduced during the seventeenth and eighteenth centuries are still in use today. Opium ***(morphine)*** is a good example of one drug still in use. Accurate studies of drug dosage in the nineteenth century led to the development of manufacturing facilities to produce drugs. In addition, knowledge of the expected actions of these drugs became more exact. Important drug discoveries in the twentieth and twenty-first

(Courtesy Ray Kemp. St. Charles, Mo.)

centuries (e.g., ***insulin,*** antibiotics, and fibrinolytics) have had major effects on common illnesses such as diabetes, bacterial infections, and cardiovascular disease.

Modern health care and **pharmaceutics** are undergoing many changes due in large part to consumer awareness of disease prevention. Changes also come from the consumers' drive to take responsibility for their health and wellness. The health care and pharmaceutical industries actively seek to develop new drugs, treatments, cures, or other methods to prevent diseases that affect aging, everyday living, or life span. The federal government also provides incentives to pharmaceutical companies to research and develop less profitable drugs. These drugs are called **orphan drugs.** They treat rare, chronic diseases such as hemophilia, leprosy, Cushing's syndrome, and Tourette's syndrome.

NOTE

The term orphan drug refers to a medication that has been developed specifically to treat a rare medical condition (an *orphan disease*). The assignment of orphan status to a disease and to any drugs developed to treat it is a matter of public policy in many countries. Medical breakthroughs have resulted from these assignments. Some of these medical advancements would not have otherwise been achieved because of the economics of drug research and development.

Investigational drugs are drugs that are under study and not yet approved by the U.S. Food and Drug Administration for sale in the United States. The most common way patients receive these drugs is by taking part in clinical trials. Specific criteria must be met to receive an investigational drug outside a clinical trial. In general, these drugs are provided free of charge.

Drug Names

A **drug** may be defined as "any substance taken by mouth, injected into a muscle, blood vessel, or cavity of the body, or applied topically to treat or prevent a disease or

FIGURE 13-1 **A,** Foxglove. **B,** Deadly nightshade. These are the plant sources of digoxin and atropine, respectively. (From Page CP et al: *Integrated pharmacology,* ed 3, St Louis, 2006, Mosby.)

condition."[2] Drugs have been identified or derived from five major sources. These sources are plants (alkaloids, glycosides, gums, and oils), animals and human beings, minerals or mineral products, microorganisms, and chemical substances made in the laboratory (Box 13-1).

Drugs can be identified by the following four types of names:

BOX 13-1 Examples of Drugs and Their Sources

Plant Sources
Digoxin
Morphine sulfate
Atropine sulfate

Animal and Human Sources
Epinephrine
Insulin
Adrenocorticotropic hormone

Mineral or Mineral Product
Calcium chloride
Iodine
Iron
Sodium bicarbonate

Microorganism Sources
Penicillin
Streptomycin

Laboratory-Produced Chemicals
Diazepam (Valium)
Lidocaine (Xylocaine)
Midazolam (Versed)

1. **Chemical name:** The chemical name is an exact description. It describes the chemical composition of the drug. It also describes its molecular structure.
2. **Generic name** (nonproprietary name): This name often is an abbreviated form of the chemical name. The generic name is used more commonly than the chemical name. Generic drugs usually have the same therapeutic efficacy as nongeneric drugs. However, they generally are less expensive. This is the official name approved by the U.S. Food and Drug Administration (FDA).

DID YOU KNOW?
FDA approval is the final step in the process of drug development. The first step is for the new drug to be tested in the laboratory. If the results are promising, the drug company or sponsor must apply for FDA approval to test the drug in people. This is called an Investigational New Drug (IND) Application. Once the IND is approved, clinical trials can begin. Clinical trials are research studies to determine the safety and to measure the effectiveness of the drug in people. Once clinical trials are completed, the sponsor submits the study results in a New Drug Application (NDA) or Biologics License Application (BLA) to the FDA. This application is carefully reviewed; if the drug is found to be reasonably safe and effective, it is approved.[3]

3. **Trade name** (brand or proprietary name): The trade name is a trademark name designated by the drug company that sells the medication. Trade names are proper nouns, and the first letter is capitalized. This text

shows the trade name in parentheses after the generic name of the drug. The trade name usually is suggested by the first manufacturer of the drug.

4. **Official name:** The official name of a drug is followed by the initials *USP* (*United States Pharmacopeia*) or *NF* (*National Formulary*). These initials denote the listing of the drug in one of the official publications. In most cases the official name is the same as the generic name.

An example of the four names for a drug would be as follows:

Chemical name:	(–)-17-allyl-4-5α-epoxy-3,14-dihydroxymorphinan-6-one-hydrochloride
Generic name:	naloxone hydrochloride
Trade name:	Narcan
Official name:	naloxone hydrochloride USP

Sources of Drug Information

Several publications offer information on various drugs, their preparation, and recommended administration. These references include the *American Medical Association Drug Evaluation,* the *American Hospital Formulary Service Drug Information,* medication package inserts, the *Physicians' Desk Reference,* and the *Nursing Drug Reference* (Box 13-2). Paramedics should be familiar with these and with other emergency pharmacology manuals as well. This is crucial particularly regarding drugs that often are administered in the prehospital setting. Reliable Internet sources and computer application software (e.g., Epocrates) for hand-held devices (e.g., PDAs, Smartphones) also can be a good source of information about pharmacotherapeutics. In addition, the findings of current research can be found on the Internet. This research provides details about certain drug studies and treatments.

BOX 13-2 Drug References

American Medical Association Drug Evaluation: The *Drug Evaluation* provides information on drug groups, dosages, prescribing information, and usage. It also covers valid clinical applications of drug use that differ from those approved by the Food and Drug Administration thus far.

Hospital Formulary: The *Hospital Formulary,* a manual published by the American Society of Hospital Pharmacists, provides an overview in monograph form of nearly every available (approved and unapproved) drug in the United States. The formulary is updated regularly and is available in all hospital pharmacies and in many emergency departments. The *Hospital Formulary* is considered by many to be the most reliable source of information on medications and drugs.

Medication package inserts: Most medications are packaged with written literature describing product use. These inserts provide valuable information as new drugs are introduced, and the health care professional should consult them to become familiar with the product.

Physicians' Desk Reference: The *Physicians' Desk Reference,* published yearly by the Medical Economics Company, is a concise compilation of drug information, including FDA-approved indications, contraindications, and adverse effects. In addition to providing product information through several cross-referenced indexes, the textbook serves as an identification guide by showing actual-size, color pictures of commonly prescribed medications. The *Physicians' Desk Reference* also lists emergency telephone numbers for poison control centers throughout the United States.

Nursing Drug Reference: The *Nursing Drug Reference* is published yearly and includes nursing considerations, side effects, adverse reactions, precautions, interactions, and contraindications for drug and intravenous therapy. The textbook contains an alphabetical listing of commonly prescribed drugs and detailed monographs for drugs recently approved by the Food and Drug Administration.

Drug Standards and Legislation

Before 1906 little control was exercised over the use of medications. Drugs often were sold or distributed by traveling medicine men, drugstores, mail order companies, and legitimate and self-proclaimed physicians. The ingredients of drugs were not required to be listed. In fact, many drug products contained opium, heroin, and alcohol, which could be potentially harmful to the user.

In 1906 Congress passed the Pure Food and Drug Act. This act was meant to protect the public from mislabeled or adulterated drugs. The act prohibited the use of false and misleading claims for drugs. The act also restricted the sale of drugs with a potential for abuse (Table 13-1). The act designated the *United States Pharmacopeia* and the *National Formulary* as official standards and empowered the federal government to enforce these standards. In 1980 the United States Pharmacopeial Convention purchased the *National Formulary*. This made the *United States Pharmacopeia* the only official book of drug standards in the United States. In addition to the *United States Pharmacopeia,* other drug standards and legislation are listed in Box 13-3.

Standardization of drugs is necessary because drugs made by different manufacturers (brand name versus generic) may vary significantly in strength and activity. The strength, purity, or effectiveness of a drug can be measured through chemical analysis in a lab. This process is known as *assay*. A concentration of a drug can be determined by comparing its effect on an organism, animal, or isolated tissue to that of a drug that produces a known effect. This process is known as *bioassay* (biological assay). Bioassay is used to measure the bioequivalence, or relative therapeutic effectiveness, of two chemically equivalent drugs.

TABLE 13-1 Controlled Substances

Characteristics	Dispensing Restrictions	Examples
Schedule I		
Has high abuse potential Has no accepted medical use; for research, analysis, or instruction only May lead to severe dependence	Approved protocol is required.	Heroin, marijuana (cannabis), tetrahydrocannabinols, lysergic acid diethylamide (LSD), mescaline, peyote, psilocybin, methaqualone, MDMA (ecstasy)
Schedule II		
Has high abuse potential Has accepted medical uses May lead to severe physical or psychological dependence or both	Written prescription is necessary (signed by the practitioner); only emergency dispensing is permitted without written prescription (only required amount may be prescribed for emergency period). No prescription refills are allowed. Container must have warning label.*	Opium, morphine sulfate, hydromorphone, meperidine, codeine, oxycodone, methadone, secobarbital, pentobarbital, amphetamine, fentanyl, methylphenidate, cocaine, and others
Schedule III		
Has less abuse potential than drugs in schedules I and II Has accepted medical uses May lead to moderate to low physical dependence or high psychological dependence	Written or oral prescription is required. Prescription expires in 6 months. No more than five refills are allowed in a 6-month period. Container must have warning label.*	Preparations containing limited quantities of or combined with one or more active ingredients that are noncontrolled substances (codeine, hydrocodone, morphine sulfate, dihydrocodeine, or ethylmorphine) and nonnarcotic drugs such as derivatives of barbituric acid, except those that are listed in another schedule, glutethimide, methyprylon, chlorphentermine, paregoric, and others
Schedule IV		
Has lower abuse potential compared with schedule III drugs Has accepted medical uses May lead to limited physical or psychological dependence	Written or oral prescription is required. Prescription expires in 6 months, with no more than five refills allowed. Container must have warning label.*	Barbital, phenobarbital, chloral hydrate, meprobamate, fenfluramine, chlordiazepoxide, diazepam, oxazepam, clorazepate, flurazepam, lorazepam, dextropropoxyphene, pentazocine, mazindol, alprazolam, and others
Schedule V		
Has low abuse potential compared with schedule IV drugs Has accepted medical uses May lead to limited physical or psychological dependence	Drug may require written prescription or may be sold without prescription (check state law).	Medications (generally for relief of coughs or diarrhea) that contain limited amounts of certain opioid controlled substances

*The warning must read "Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed."

NOTE

The Controlled Substances Act was passed in 1970. A controlled substance is any drug that is defined in the categories of the Act. These categories include opium and its derivatives, hallucinogens, depressants, and stimulants. It is illegal for any person to possess a controlled substance, unless the substance was obtained by a valid prescription or physician's order. A person may also possess a controlled substance if the possession of the drug is pursuant to actions in the course of professional practice. The authority for use of controlled substances and other prescription drugs is a function of state agencies. These agencies operate under restrictions of the federal government. The restrictions are provided by the federal Drug Enforcement Agency. Paramedics and other allied health workers who administer drugs should be familiar with state laws governing the administration and storage of drugs. They also should be familiar with the record-keeping requirements. Violations of the act are punishable by fine or imprisonment, or both.

BOX 13-3 History of Drug Standards and Legislation

1912: Congress passed the Sherley Amendment prohibiting fraudulent therapeutic claims.

1914: The Harrison Narcotic Act was passed to control the sale of narcotics and to help curb drug addiction or dependence. This was the first narcotic act to be passed by any nation, and it established the word narcotic as a legal term.

1938: Prompted by more than 100 deaths in 1937 from ingestion of a diethylene glycol solution of sulfanilamide, the federal Food, Drug, and Cosmetic Act was passed. This act contained a provision to prevent marketing of a new drug before it was tested properly. In addition, the act required that the label list all ingredients used in preparing the drug and the directions for drug use.

1952: The Durham-Humphrey Amendment changed the 1938 drug act, restricting the dispensing of legend (prescription) drugs. Legend drugs must bear the legend "Caution: Federal law prohibits dispensing without prescription."

1962: The Kefauver-Harris Amendment required that the safety and efficacy of a new drug be proved before the drug could be approved for use.

1970: The Comprehensive Drug Abuse Prevention and Control Act (also known as the Controlled Substances Act) superseded the Harrison Narcotic Act of 1914. The Controlled Substances Act classifies a controlled substance by its use and abuse potential. Drugs are classified into numbered schedules from schedule I (drugs with highest abuse potential) to schedule V (drugs with lowest abuse potential) (see Table 13-1).

Drug Regulatory Agencies

In July 1973 the Drug Enforcement Agency, an agency of the Department of Justice, became the sole legal drug enforcement body in the United States. Other regulatory bodies or services include the following:

CRITICAL THINKING

News stories often feature miracle drugs. These drugs are used in other countries but are not yet available in the United States. They are not available because they lack Food and Drug Administration approval. Why would the Food and Drug Administration not automatically approve drugs already known to be helpful in the international market?

- Food and Drug Administration: The FDA is responsible for enforcing the federal Food, Drug, and Cosmetic Act of 1937. The FDA may seize offending goods and criminally prosecute individuals involved.
- Public Health Service: The Public Health Service is an agency of the U.S. Department of Health and Human Services. One of the duties of the Public Health Service is to regulate biological products, which include viruses, therapeutic serums, antitoxins, or analogous products applicable in the prevention or cure of human diseases or injuries. The agency examines and licenses these products and inspects and licenses the establishments that produce them.
- Federal Trade Commission: The Federal Trade Commission is an agency of the federal government directly responsible to the President of the United States. Its principal action with respect to drugs lies in its power to suppress false or misleading advertising aimed at the public.
- Canadian drug control: In Canada the Health Protection Branch of the Department of National Health and Welfare is responsible for administering and enforcing the Food and Drugs Act, the Proprietary or Patent Medicine Act, and the Narcotics Control Act.
- International drug control: International control of drugs began in 1912 when the first "Opium Conference" was held at The Hague. Various international treaties were adopted, obligating governments to control narcotic substances. These treaties were consolidated in 1961 into one document, known as the *Single Convention on Narcotic Drugs,* which became effective in 1964. Later the International Narcotics Control Board was established to enforce this law.

CRITICAL THINKING

Your patient is acutely ill. She reports taking only an herbal medicine, which is not found in standard drug reference materials. Where can you or the medical staff find information about these alternative therapies?

SECTION TWO
Mechanisms of Drug Action

GENERAL PROPERTIES OF DRUGS

Drugs may act in the body in many ways. Some of these actions are desirable (a *therapeutic effect*). Others are considered undesirable or even harmful (a *side effect*). Drugs also may interact with other drugs. Interaction may produce uncommon and frequently unpredictable effects. (Allergic reactions to drugs are discussed in Chapter 27.) In addition, drugs generally exert several effects rather than a single one.

NOTE

It is critical for the paramedic to perform a thorough patient assessment. The paramedic also must obtain a pertinent medical (and drug) history from the patient. Being able to recognize and understand the reasons why certain drugs are prescribed for certain conditions or diseases is important. This knowledge can help establish a field diagnosis for the patient based on the assessment and physical findings. By having a thorough understanding of drug actions/interactions, the paramedic should be able to use the right drug to manage the illness, disease, or condition.

One should note that *drugs do not confer any new functions on a tissue or organ; they only modify existing functions*. As is described later in this chapter, the actions of a drug are achieved by a biochemical interaction between the drug and certain tissue components in the body (usually receptors). A drug that interacts with a receptor to stimulate a response is known as an **agonist.** A drug that attaches to a receptor but does not stimulate a response is called an **antagonist.** Box 13-4 contains other pharmacological terms and their definitions.

To produce the desired effect, a drug first must enter the body. Then the drug must reach appropriate concentrations at its site of action. This process is influenced by three phases of drug activity: the *pharmaceutical phase,* the *pharmacokinetic phase,* and the *pharmacodynamic phase*.

Pharmaceutical Phase

Pharmaceutics is the science of dispensing drugs. One aspect of this field is the study of the ways in which the forms of drugs (solid or liquid) influence pharmacokinetic and pharmacodynamic activities (described in the following sections). All drugs must be in solution to cross the cell membranes to achieve absorption. The term *dissolution* refers to the rate at which a solid drug goes into solution after ingestion. The faster the rate of dissolution, the more quickly the drug is absorbed.

Pharmacokinetic Phase

Pharmacokinetics is the study of how the body handles a drug over a period of time. This includes the processes of absorption, distribution, biotransformation, and excretion. These factors affect a patient's response to drug therapy.

DRUG ABSORPTION

Absorption involves the movement of drug molecules from the entry site to the general circulation. The degree to which drugs attain pharmacological activity depends partly on the rate and extent to which they are absorbed. The rate and extent in turn depend on the ability of the drug to cross the cell membrane. The drug crosses the membrane through the processes of passive diffusion and active transport (described in Chapter 11). Most drugs enter the cell by passive diffusion. Yet some drugs require a carrier-mediated mechanism to assist them across the membrane.

LOOK AGAIN

See Chapter 11: General Principles of Pathophysiology, pp. 218-220.

Absorption begins at the site of administration. The rate and extent of absorption depend on the following factors[4]:

1. *The nature of the absorbing surface (cell membrane) the drug must traverse:* If a drug must pass through a single layer of cells such as the intestinal epithelium, transport is faster than if the drug must pass through several layers of cells (e.g., the skin). In addition, the greater the surface area of the absorbing site, the greater the absorption and the quicker the drug takes effect. For example, the small intestine offers a large absorption area, whereas the stomach has a relatively small absorption surface area.
2. *Blood flow to the site of administration:* A rich blood supply enhances absorption, and a poor blood supply delays it. For example, a patient with diminished blood flow may

BOX 13-4 Pharmacological Terminology

Antagonism: The opposition of effects between two or more medications that occurs when the combined (conjoint) effect of two drugs is less than the sum of the drugs acting separately

Contraindications: Medical or physiological factors that make it harmful to administer a medication that would otherwise have therapeutic value

Cumulative action: The tendency for repeated doses of a drug to accumulate in the blood and organs, causing increased and sometimes toxic effects; it occurs when several doses are administered or when absorption occurs more quickly than removal by excretion or metabolism

Depressant: A substance that decreases a body function or activity

Drug allergy: A systemic reaction to a drug resulting from previous sensitizing exposure and the development of an immunological mechanism

Drug dependence: A state in which withdrawal of a drug produces intense physical or emotional disturbance; previously known as habituation

Drug interaction: Beneficial or detrimental modification of the effects of one drug by the prior or concurrent administration of another drug that increases or decreases the pharmacological or physiological action of one or both drugs

Idiosyncrasy: Abnormal or peculiar responses to a drug (accounting for 25% to 30% of all drug reactions) thought to result from genetic enzymatic deficiencies or other unique physiological variables and leading to abnormal mechanisms of drug metabolism or altered physiological effects of the drug

Potentiation: The enhancement of effect caused by the concurrent administration of two drugs in which one drug increases the effect of the other drug

Side effect: Undesirable and often unavoidable effect of using therapeutic doses of a drug; action or effect other than those for which the drug was originally given

Stimulant: A drug that enhances or increases body function or activity

Summation: The combined effect of two drugs such that the total effect equals the sum of the individual effects of each agent (1 + 1 = 2)

Synergism: The combined action of two drugs such that the total effect exceeds the sum of the individual effects of each agent (1 + 1 = 3 or more)

Therapeutic action: The desired, intended action of a drug

Tolerance: Decreased physiological response to the repeated administration of a drug or chemically related substance, possibly necessitating an increase in dosage to maintain a therapeutic effect (tachyphylaxis)

Untoward effect: A side effect that proves harmful to the patient

not respond to intramuscular administration of a drug because diminished circulation reduces absorption. In contrast, intravenous administration of a drug immediately places the drug in the circulatory system, where it is absorbed completely and delivered to its target tissue.

3. *The solubility of the drug:* The more soluble the drug, the more rapidly it is absorbed. For example, drugs that are prepared in oily solutions are absorbed more slowly than drugs dissolved in water or in isotonic sodium chloride.
4. *The pH of the drug environment:* In solution, many drugs exist in an ionized (electrically charged) and nonionized (uncharged) form. A nonionized drug is lipid (fat) soluble and readily diffuses across the cell membrane. An ionized drug is lipid insoluble and generally does not cross the cell membrane. Most drugs do not ionize fully following administration. Rather, they reach an equilibrium between their ionized and nonionized forms, allowing for the nonionized form to be absorbed. Both the mechanism and the extent of ionization depend on whether the drug is an acid or a base. An acidic drug such as ***aspirin*** is relatively nonionized and does not dissociate well in an acidic environment such as the stomach; therefore it is absorbed easily in the stomach. A drug that is basic in the same acidic environment tends to ionize and is not absorbed easily through the gastric membrane. The reverse occurs when the drug is in an alkaline medium.
5. *The drug concentration:* Drugs administered in high concentrations tend to be absorbed more rapidly than those administered in low concentrations. In some situations, administration of a **loading dose** (large dose) first that temporarily exceeds the capacity for excretion of the drug is necessary. This rapidly establishes a therapeutic drug level at the receptor site. A **maintenance dose** (smaller dose) then can be administered to replace the amount of drug excreted. Thus loading doses are based more on the volume of distribution (of which body size is an important component) and less on capacity for excretion (e.g., renal failure). Maintenance doses are exactly the opposite.
6. *The form of the drug dosage:* Drug absorption can be manipulated by pharmaceutical processing. An example is a combination of an active drug with another substance that is slowly released or a drug that resists digestive action (e.g., those with enteric coatings).

CRITICAL THINKING

Consider a common condition seen in the prehospital setting. This condition requires that drugs be given at higher than usual doses to achieve therapeutic levels. What is the condition?

ROUTES OF DRUG ADMINISTRATION

The mode of drug administration affects the rate at which onset of action occurs. Route of administration also may affect the therapeutic response that results. The routes of drug administration are categorized as follows:

- Enteral (administration along any portion of the gastrointestinal tract)
- Parenteral (administration by any route other than the gastrointestinal tract)
- Pulmonary (administration by inhalation or through an endotracheal tube)
- Topical (administration by application to the skin and mucous membranes)

The route of administration greatly influences drug absorption (Table 13-2). Chapter 14: describes the methods used to administer drugs by various routes.

Enteral Route. Drugs administered along any portion of the gastrointestinal tract are said to use the enteral route (Box 13-5). Administration may be orally, rectally, or through a gastric tube. The enteral method of giving drugs is the safest, most convenient route. This route also is the most economical route of administration. Yet the enteral route is the least reliable and slowest of the common routes because of the frequent changes in the gastrointestinal environment (e.g., with food contents, emotional state, and physical activity). This route allows four types of absorption: oral absorption, gastric absorption, absorption from the small intestine, and rectal absorption.

Oral Absorption. The oral cavity has a rich blood supply. However, little absorption normally occurs in the mouth. Certain drugs, such as ***nitroglycerin*** (Nitrostat) tablets and some hormones, are prepared to be absorbed orally. When administered by sublingual or buccal routes, these drugs rapidly dissolve in the salivary secretions and are absorbed by the oral mucosa. Drugs that are absorbed in the upper gastrointestinal tract enter the systemic circulation. They

TABLE 13-2 Comparison of Drug Absorption Rates by Common Routes of Administration

Route	Rate of Absorption
Enteral	Slow
Sublingual	Rapid
Subcutaneous	Slow
Intramuscular	Moderate
Intravenous	Immediate (no absorption required)
Endotracheal	Rapid
Intraosseous	Immediate
Pulmonary	Rapid
Topical	Moderate

BOX 13-5 Some Emergency Drugs Administered via the Enteral Route

Activated charcoal
Aspirin

initially bypass gastrointestinal fluids and the liver. Drugs absorbed in the stomach and intestines pass through the portal vein system of the liver. They are subject to **first-pass metabolism** in the liver. *(First-pass metabolism refers to the concentration of a drug being reduced before it reaches the systemic circulation. It will be described in full later in this chapter.)* In the sublingual route the drug is placed under the tongue. The tablet or spray dissolves in the salivary secretions. The effects of sublingual medication usually are clear within a few minutes. With buccal administration the drug is placed between the teeth and mucous membrane of the cheek. As in the sublingual route, absorption by buccal administration usually is rapid.

CRITICAL THINKING

Nitroglycerin spray may be more effective in geriatric patients than the tablet form. Why do you think this is the case?

Gastric Absorption. The stomach also has a rich blood supply but is not considered an important site of drug absorption. The length of time a medication remains in the stomach varies, depending on the pH of the environment and gastric motility. As previously described, weakly acidic drugs tend to remain nonionized. These drugs are absorbed readily into the circulation. In comparison, basic drugs ionize in the stomach and are absorbed poorly. Altering the gastric emptying rate may alter the rate and extent of drug absorption. Many drugs are administered on an empty stomach with sufficient water (8 oz) to ensure rapid passage into the small intestine. Other drugs cause gastric irritation and usually are given with food.

Absorption From the Small Intestine. The small intestine has a rich blood supply. Thus it has a larger absorption area than the stomach. Most drug absorption occurs in the upper part of the small intestine. The pH of intestinal fluid is alkaline, which increases the rate of absorption of basic drugs. Prolonged exposure allows more time for drug absorption. An increase in intestinal motility (e.g., diarrhea) decreases exposure to the intestinal membrane and diminishes absorption.

Rectal Absorption. The surface area of the rectum is not large. However, the rectum is vascular and capable of drug absorption. Drugs administered rectally are subject to erratic absorption because of rectal contents, local drug irritation, and the uncertainty of drug retention. Fifty percent of a drug that has been administered rectally is estimated to bypass the liver after absorption. This makes first-pass metabolism by the liver less than that of an orally given dose.

CRITICAL THINKING

The drugs given rectally in emergencies usually are anticonvulsants. Why do you think this route would be chosen over the oral or intravenous route?

BOX 13-6 Examples of Emergency Drugs Administered via the Parenteral Route

Adenosine (Adenocard)
Amiodarone (Cordarone)
Atropine
Dextrose 50%
Diazepam (Valium)
Diphenhydramine (Benadryl)
Dopamine (Intropin)
Epinephrine (Adrenalin)
Fentanyl (Sublimaze)
Lidocaine (Xylocaine)
Lorazepam (Ativan)
Midazolam (Versed)
Morphine
Naloxone (Narcan)
Oxytocin (Pitocin)
Vasopressin (Pitressin)
Verapamil (Isoptin)

Parenteral Route. Drugs administered by injection are said to use the parenteral route (Box 13-6). The commonly used parenteral routes for administering medications include the following:

1. *Subcutaneous route:* A subcutaneous injection is given beneath the skin into the connective tissue or fat immediately beneath the dermis. This route is used only for small volumes of drugs (0.5 mL or less) that do not irritate tissue. The rate of absorption usually is slow and can provide a sustained effect.
2. *Intramuscular route:* An intramuscular injection is given into the skeletal muscle. Absorption generally occurs more rapidly than with a subcutaneous injection because of greater tissue blood flow.
3. *Intravenous route:* An intravenous injection is given directly into the bloodstream, bypassing the absorption process. This route produces an almost immediate pharmacological effect. Most intravenous drugs should be administered slowly to help prevent adverse reactions.
4. *Intradermal route:* An intradermal injection is made just below the epidermis. This route primarily is used for allergy testing and to administer local anesthetics. Drugs given by this route are not absorbed into the general circulation.
5. *Intraosseous route:* An intraosseous injection is given directly into the bone marrow cavity of pediatric and adult patients through an established intraosseous infusion system. Agents infused by this method are thought to circulate via the medullary cavity of the bone. Through the numerous venous channels of long bones, fluids or drugs rapidly enter the central circulation. The length of time from injection to entry into the systemic circulation is thought to equal that of the intravenous route.[5] Emergency medications known to be effective when administered via the intraosseous route are ***amiodarone***

(Cordarone), ***epinephrine*** (Adrenalin), ***atropine, sodium bicarbonate, dopamine*** (Intropin), ***dobutamine*** (Dobutrex), and ***lidocaine*** (Xylocaine).

NOTE
Although all resuscitation drugs can be given by the intraosseous (IO) route, administration of ceftriaxone, chloramphenicol, phenytoin, tobramycin, and vancomycin may result in lower peak serum concentrations.[6]

6. *Endotracheal route*: Access to the endotracheal route generally is through an endotracheal tube, which allows drug delivery into the alveoli and systemic absorption via the capillaries of the lungs. Administration of drugs via an endotracheal tube usually is reserved for situations in which an intravenous or intraosseous line cannot be established. Medications that can be administered by the endotracheal tube include ***naloxone*** (Narcan), ***atropine, vasopressin*** (Pitressin), ***epinephrine*** (Adrenalin), and ***lidocaine*** (Xylocaine). Administration of 2 to 2½ times the recommended intravenous dose (diluted in 10 mL of normal saline) is recommended when medication is given by this route.[7]

NOTE
A mnemonic for the five medications that may be administered via the pulmonary route through an endotracheal tube is *N-A-V-E-L,* which stands for *n*aloxone, *a*tropine, *v*asopressin, *e*pinephrine, and *l*idocaine.

Pulmonary Route. Medication can be administered by inhalation in the form of gas or fine mist (aerosol). The most commonly used inhalation medications are bronchodilators (Box 13-7). However, the pulmonary circulation can absorb a number of other medications if necessary, such as drugs for endotracheal administration.

Because of the large surface area and the rich capillary network of the alveoli, drug absorption into the bloodstream is rapid. Bronchodilators and steroids can be given by inhalation devices, such as a nebulizer (described in Chapter 14). A nebulizer propels the drug into alveolar sacs. Drugs that are given by a nebulizer device produce mainly local effects. Occasionally, nebulized drugs can produce unwanted systemic effects. An example of these effects is an elevated heart rate (tachycardia).

Topical Route—Skin. In most cases, drugs applied topically to the skin and mucous membranes are absorbed rapidly (Box 13-8). Only lipid-soluble compounds are absorbed through the skin. The skin acts as a barrier to most water-soluble compounds. To prevent adverse systemic effects, intact skin surfaces should be used as an administration site. Massaging the skin helps to promote drug absorption because it dilates capillaries and increases local blood flow.

Topical Route—Nasal. As described in Chapter 10, the nasal mucosa is highly vascular. The delivery of medication via the intranasal route results in rapid absorption of the medication into the bloodstream and cerebrospinal fluid. This results in therapeutic drug levels that are effective in the management of seizures, pain, hypoglycemia, opiate overdose, and other medical conditions (Box 13-9). Using the intranasal route greatly reduces the risk of needle-stick injury. Some vaccines are also administered by the intranasal route in select patient groups. Examples of these include live attenuated influenza vaccine (LAIV) and influenza virus vaccine live (Intranasal FluMist) (see Chapter 14).

DRUG DISTRIBUTION

Distribution is the transport of a drug through the bloodstream. The drug is transported to various tissues of the body and ultimately to its site of action. After a drug has entered the circulatory system, it is distributed rapidly throughout the body. The rate at which distribution occurs depends on the permeability of capillaries to the drug molecules.

To review, lipid-soluble drugs readily cross capillary membranes to enter most tissues and fluid compartments. Lipid-insoluble drugs require more time to arrive at their point of action. Cardiac output and regional blood flow

BOX 13-7 Emergency Drugs Administered via the Pulmonary Route

Albuterol (Proventil, Ventolin)
Amyl nitrite
Epinephrine racemic (microNefrin)
Levalbuterol (Xopenex)
Metaproterenol (Alupent)
Nitrous oxide/oxygen (Nitronox)
Oxygen

BOX 13-8 Emergency Drugs Administered via the Topical Route

Lidocaine (lidocaine gel)
Nitropaste (Nitro-Bid ointment)

BOX 13-9 Emergency Drugs Administered via the Nasal Route

Diazepam (Valium)
Fentanyl (Sublimaze)
Glucagon
Haloperidol (Haldol)
Lidocaine (Xylocaine)
Lorazepam (Ativan)
Midazolam (Versed)
Naloxone (Narcan)

also affect the rate and extent of distribution into body tissues. Generally, a drug is distributed first to organs that have a rich blood supply. These organs include the heart, liver, kidneys, and brain. Then, depending on its composition, the drug enters tissue with a lesser blood supply, such as muscle and fat.

Drug Reservoirs. Drugs may accumulate at certain locations that act as storage sites. At these sites the drugs form reservoirs by binding to specific tissues. As serum levels decline, tissue-bound drug is released from its storage site into the bloodstream. The released drug maintains the serum drug levels and may permit sustained release of the drug over time. This allows continued pharmacological effect at the receptor site. The two general processes that create drug reservoirs are *plasma protein binding* and *tissue binding*.

As drugs enter the circulatory system, they may attach to plasma proteins (mainly albumin), forming a **drug-protein complex.** The extent to which this binding occurs affects the intensity and duration of the effect of the drug. The albumin molecule is too large to diffuse through the membrane of the blood vessel. Thus albumin traps the *bound drug* in the bloodstream. A drug bound to plasma protein is pharmacologically inactive. The protein becomes a circulating drug reservoir. The *free drug* (non–protein-bound drug) exists in proportion to the protein-bound fraction and is the only portion of the drug that is biologically active. As the free drug is eliminated from the body, the drug-protein complex dissociates, and more drug is released to replace the free drug that was metabolized or excreted. This process is summarized in the following equation:

$$\text{Free drug} + \text{Protein} \Rightarrow \text{Drug-protein complex}$$

Albumin and other plasma proteins provide a number of binding sites. Yet two drugs can compete for the same site and displace each other. Certain combinations of drugs may be given at the same time. As a result, this competition can have serious consequences. For example, a patient taking the anticoagulant drug warfarin (Coumadin) may be given quinidine (e.g., Quinaglute Dura Tabs). The quinidine may displace some of the protein-bound warfarin. This may cause warfarin toxicity and in turn can lead to severe hemorrhage.

Other factors that influence the binding ability of a drug include the concentration of plasma proteins (especially albumin), the number of binding sites on the protein, the *affinity* (attraction) of the drug for the protein, and the acid-base balance of the patient. Various disease states, such as liver disease, alter the ability of the body to handle many medications. These alterations result from a decrease in serum albumin levels (albumin is manufactured by the liver) and a decrease in hepatic metabolism. These and other factors may result in more free drug being available for distribution to tissue sites (increased free drug fraction and enhanced pharmacological response).

A second type of "drug pooling" occurs in fat tissue and bone. Lipid-soluble drugs have a high affinity for adipose tissue, where these drugs are stored. Because fat tissue has low blood flow, it serves as a stable reservoir for drugs. Some lipid-soluble drugs can remain in body fat for as long as 3 hours after administration. Other drugs (e.g., tetracycline) have an unusual affinity for bone. These drugs accumulate in bone after being absorbed onto the bone crystal surface.

CRITICAL THINKING

Tetracycline typically is not given to pregnant women because of the harmful effects it has on the development of the baby's teeth. Why would it affect the teeth?

Barriers to Drug Distribution. The blood-brain barrier and the placental barrier are protective membranes. These membranes prevent the passage of certain drugs into these body sites. The **blood-brain barrier** consists of a single layer of capillary endothelial cells. These cells line the blood vessels entering the central nervous system. The cells are tightly joined at common borders by continuous intercellular junctions. This special arrangement permits only lipid-soluble drugs to be distributed into the brain and cerebrospinal fluid. Examples of such drugs are general anesthetics and barbiturates. Drugs that are poorly soluble in fat (e.g., many antibiotics) have trouble passing this barrier. Thus they cannot enter the brain.

The **placental barrier** is made up of membrane layers. These layers separate the blood vessels of the mother and the fetus. Like the blood-brain barrier, the placental barrier is not permeable to many lipid-insoluble drugs. Thus the placenta offers some protection to the fetus. However, the placenta does allow the passage of certain non–lipid-soluble drugs. Examples of these are steroids, narcotics, anesthetics, and some antibiotics. If these drugs are given to the pregnant mother, they may affect the developing embryo or fetus or the neonate. (Pregnancy Category ratings for drugs are described later in this chapter.)

BIOTRANSFORMATION

After absorption and distribution, the body eliminates most drugs, first by biotransformation and then by excretion. **Biotransformation** (metabolism) is a process in which drugs are chemically converted to *metabolites* (smaller components). The purpose of biotransformation usually is to "detoxify" a drug and render it less active. The liver is the primary site of drug metabolism. However, other tissues also can be involved. Some of these include the plasma, kidneys, lungs, and the intestinal mucosa.

Orally administered drugs that are absorbed through the gastrointestinal tract normally travel to the liver before entering the general circulation. When this occurs, a large amount of the drug may be metabolized before reaching the systemic circulation. This is known as *first-pass metabolism*. This reduces the amount of drug that is available for distribution in the body. Medications affected by this initial

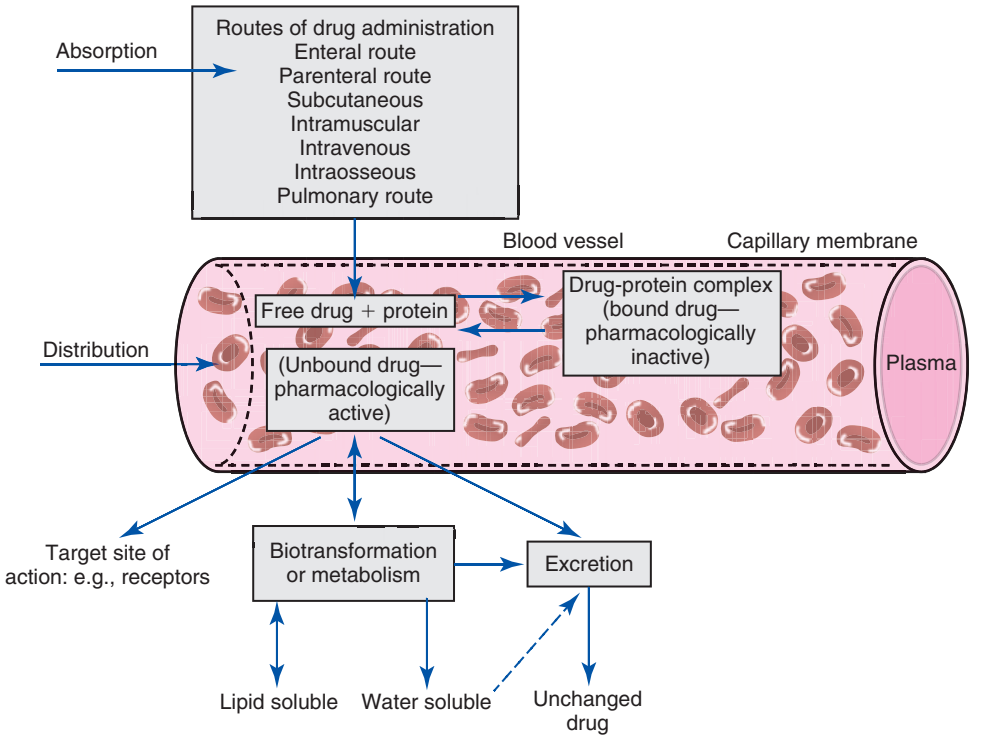

FIGURE 13-2 Pharmacokinetic phase of drug action, showing absorption, distribution, biotransformation, and excretion of drugs. Only free drug is capable of movement for absorption, distribution to the target site of action, biotransformation, and excretion. The drug-protein complex represents bound drugs; because the molecule is large, it is trapped in the blood vessel and serves as a storage site for the drug.

biotransformation in the liver may be given in higher dosages or administered parenterally (intravenously or intramuscularly) to bypass the liver.

Individuals metabolize drugs at variable rates. For example, patients with liver, renal, or cardiovascular disease are expected to have prolonged drug metabolism. Infants with immature metabolic capacity and older adults with degenerative metabolic function experience depressed biotransformation. If drug metabolism is delayed, drug accumulation and cumulative drug effects may occur. Therefore the paramedic may need to consider dosage reductions (particularly maintenance doses) for patients in these categories (Figure 13-2).

EXCRETION

Excretion is the elimination of toxic or inactive metabolites. The kidney is the primary organ for excretion. However, the intestine, the lungs, and the mammary, sweat, and salivary glands also may be involved.

Excretion by the Kidneys. A drug can be excreted in the urine unchanged. Or a drug can be excreted as a chemical metabolite of its previous form. Renal excretion consists of three mechanisms: passive glomerular filtration, active tubular secretion, and partial reabsorption (Figure 13-3).

Passive glomerular filtration is a simple filtration process. Filtration can be measured as the *glomerular filtration rate* (GFR) (described in Chapter 10). The GFR is the

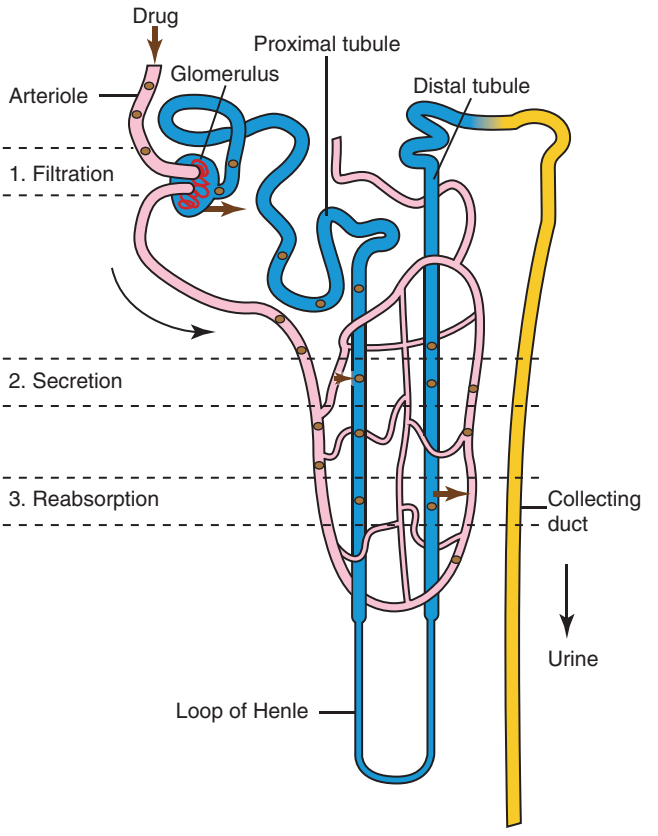

FIGURE 13-3 Drug excretion process.

total quantity of glomerular filtrate formed each minute in all nephrons of both kidneys. (This measure is usually expressed in milliliters.) The availability of a drug for glomerular filtration depends on its free concentration in plasma. Unbound drugs and water-soluble metabolites are filtered by the glomeruli. Drugs highly bound to protein do not pass through this structure.

LOOK AGAIN

See Chapter 10: Review of Human Systems, pp. 199-201.

After filtration, lipid-soluble compounds are reabsorbed by the renal tubules. Thus they reenter the systemic circulation. Water-soluble compounds are not reabsorbed. Therefore they are eliminated from the body. Because of the proportional relationship between free and bound drug, as free drug is filtered from the blood, bound drug is released from its binding sites into the plasma. The rate of excretion and the **biological half-life** of the drug (described later in this chapter) depend on how quickly bound drug is released.

CRITICAL THINKING

You pick up your patient at the renal dialysis center. How will you know which medicines you can administer safely?

Active tubular secretion occurs in the renal tubules, where free drug can be transported or secreted from the blood across the structure called the proximal tubule and from there deposited in the urine. Drugs actively secreted by the renal tubules can compete with other drugs for the same active transport process. ***Amiodarone*** (Cordarone) and ***digoxin*** (Lanoxin) is an example of a competitive drug interaction, in which the first drug reduces the removal or clearance of the second drug. (The term *clearance* refers to the complete removal of a drug by the kidneys.) The result of this competition for removal is an increase in the plasma concentration of the second drug.

Partial reabsorption is the reabsorption from the renal tubule by passive diffusion. Such reabsorption can be influenced greatly by the pH of the tubular urine. Weak acids are excreted more readily in alkaline urine. They are secreted more slowly in acidic urine. This is because they are ionized in alkaline urine but nonionized in acidic urine. The reverse is true for weak bases. For example, an increase in urinary pH decreases the reabsorption and increases the clearance of weak acids such as ***furosemide*** (Lasix) and ***aspirin***. However, a decrease in urinary pH increases the clearance of weak bases such as amphetamine and tricyclic antidepressants.

As a rule, substances that are completely or almost completely excreted by the normal kidney can be removed by an artificial process that resembles glomerular filtration. This process is *hemodialysis* (see Chapter 29). Hemodialysis can be used to remove a wide variety of substances. It is not very effective for drugs that are highly tissue- or protein-bound. Moreover, hemodialysis is of limited benefit for the removal of rapidly acting toxins.

Excretion by the Intestine. Drugs are eliminated through the intestine by biliary excretion. After liver metabolism the metabolites are carried in bile and passed into the duodenum. The metabolites then are eliminated with the feces. Some drugs are reabsorbed by the bloodstream. They are returned to the liver and then later excreted by the kidneys.

Excretion by the Lungs. Some drugs can be eliminated by the lungs. Examples are general anesthetics, volatile alcohols, and inhaled bronchodilators. Certain factors can alter drug elimination via the lungs. These factors include the rate and depth of respiration and cardiac output. Deep breathing and an increase in cardiac output (which increases pulmonary blood flow) promote excretion. However, respiratory compromise and decreased cardiac output may occur during illness or injury. This can prolong the period required to eliminate drugs through the lungs.

Excretion by the Sweat and Salivary Glands. Sweat is an unimportant means of drug excretion. However, this method can cause various skin reactions and can discolor the sweat. Drugs excreted in saliva usually are swallowed and are eliminated in the same manner as other orally administered medicines. Certain substances given intravenously can be excreted into saliva. This may cause the person to complain about the "taste of the drug" even though it was given intravenously. Examples include ***adenosine*** (Adenocard) and calcium chloride.[8]

Excretion by the Mammary Glands. Many drugs or their metabolites are excreted through the mammary glands in breast milk. Nursing mothers are advised not to take any medicine except under the supervision of a physician. Mothers usually are advised to take prescribed medicines immediately after breastfeeding. This diminishes any risk to the infant.

FACTORS THAT INFLUENCE THE ACTION OF DRUGS

Many factors can alter the response to drug therapy, including age, body mass, gender, pathological state, genetic factors, psychological factors, environment, and time of administration. The paramedic should recognize these factors and should consider individual responses. The paramedic also must consider complications that may result from drug therapy.

Age. For the most part, pediatric and geriatric patients are known to be highly sensitive to drugs. In a child, this sensitivity results in part from the immature hepatic and renal systems. In an older adult, sensitivity results from the natural decline of these systems. These aspects of body function can reduce the efficiency of excretory and metabolic mechanisms. The older patient also may have underlying disease processes. This can create unexpected responses to drug therapy. Medication doses for children usually are modified based on body weight or surface area (see Chapter 48).

Body Mass. Many drugs are given according to body mass (kilograms). An indirect relationship exists between body mass and the final concentration of drug in a patient for any given dosage (i.e., the larger the patient, the lower the concentration for any given dose of drug). The average adult drug dose is calculated on the basis of drug quantity needed to produce a particular effect when administered to 50% of the population. This population includes only persons between the ages of 18 and 65 who weigh about 150 lb (68 kg). Therefore the appropriate drug doses for children who weigh less than 150 lb and are less than 18 years old are always based on body mass.

Gender. Drug effects differ in men and women. These differences result partly from size differences. Women usually are smaller in body mass than men are. Thus they may have higher concentrations of a drug when the standard dose is administered without consideration of size. Differences in the relative proportions of fat and water in the bodies of men and women also can cause variations in drug distribution.

Environment. Drugs that affect mood and behavior may be susceptible to the individual's environment and the personality of the user. For example, sensory deprivation and sensory overload may affect a person's response to a drug. The physical environment also can affect the actions of some drugs for some persons. For example, temperature extremes and changes in altitude may increase sensitivity to some drugs.

CRITICAL THINKING

You can alter the environment in the ambulance. How might you do this to promote the action of pain-relieving drugs that you have given your patient?

Time of Administration. As previously described, the presence or absence of food in the gastrointestinal tract affects the manner in which drugs are tolerated and absorbed. Other factors that may influence drug activity and reactions to drug therapy include a person's biological rhythms (e.g., sleep-wake cycles and circadian rhythms, described in Chapter 2).

Pathological State. Illness or injury and the severity of symptoms also can play a role in a person's sensitivity to drugs. Illness or injury can affect the type and amount of drug needed to achieve a desired effect. In addition, underlying disease processes such as circulatory, hepatic, or renal dysfunction can interfere with the physiological actions of the drug and drug elimination.

Genetic Factors. Genetics can alter the response of some persons to a number of drugs. For example, this can occur through inherited diseases or enzyme deficiencies or altered receptor site sensitivities. The results of genetic abnormalities may manifest as idiosyncrasies (peculiar responses to a drug) or may be mistaken for drug allergies.

Psychological Factors. A patient's belief in the effects of a drug may strongly influence and potentiate drug effects. For example, a **placebo** (e.g., a sugar pill) can have the same result as a pharmacological agent if the patient thinks it will have the desired effect. In contrast, patient hostility and mistrust can lessen the perceived effects of a drug. The paramedic can enhance the action of a drug by telling the patient that the drug is going to work and when it will take effect.

Pharmacodynamic Phase

Pharmacodynamics is the study of how a drug acts on a living organism. This includes the pharmacological response observed relative to the concentration of the drug at an active site in the organism. As stated earlier, drugs do not confer any new function on a tissue or organ of the body; rather, they modify existing functions. Most drug actions are thought to result from a chemical interaction between the drug and various receptors throughout the body. The most common form of drug action is the **drug-receptor interaction.**

DRUG-RECEPTOR INTERACTION

It is generally believed that most drugs bind to **drug receptors** to produce their desired effect (Box 13-10). According to this theory, a specific portion of the drug molecule (the active site) selectively combines or interacts with some molecular structure (the reactive site on the cell surface or within the cell). This interaction produces a biological effect. These reactive cellular sites are known as *receptors*.

The relationship of a drug to its receptor may be thought of as a key fitting into a lock (Figure 13-4). The drug represents the key. The receptor represents the lock. The drug molecule with the best fit to a receptor produces the best

BOX 13-10 Drug-Receptor Interaction Terms

Affinity: The propensity of a drug to bind or attach itself to a given receptor site

Agonist: A drug that combines with receptors and initiates the expected response

Antagonist: An agent that inhibits or counteracts effects produced by other drugs or undesired effects caused by normal or hyperactive physiological mechanisms

Efficacy (intrinsic activity): The ability of a drug to initiate biological activity as a result of binding to a receptor site

Noncompetitive antagonist: An agent that combines with different parts of the receptor mechanism and inactivates the receptor so that the agonist cannot be effective regardless of its concentration (Noncompetitive antagonist effects are considered to be irreversible or nearly so.)

Partial antagonist: An agent that binds to a receptor and stimulates some of its effects but may antagonize the action of other drugs with greater efficacy. (Antagonists frequently share some structural similarities with their agonists.)

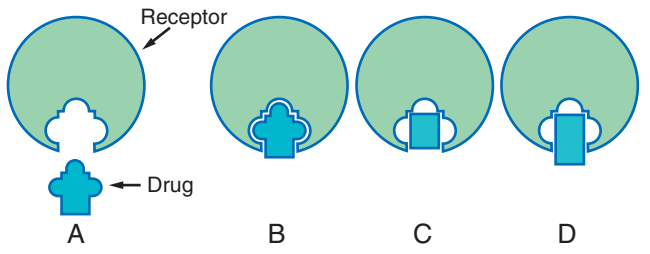

FIGURE 13-4 Lock and key fit between a drug and the receptors through which it acts. The site on the receptor that interacts with a drug has a definite shape. A drug that conforms to that shape can bind and produce a biological response. In this example, only the shape along the lower surface of the drug molecule is important in determining whether the drug binds to the receptor. (From Clayton BD, Stock YN, Harroun RD: *Basic pharmacology for nurses,* ed 14, St Louis, 2007, Mosby.)

response. Following absorption a drug is believed to gain access to a receptor after it leaves the bloodstream and is distributed to tissues that contain receptor sites. To review, drugs that bind to a receptor and cause an expected physiological response are referred to as *agonists*. Conversely, drugs that bind to a receptor and prevent a physiological response or other drugs from binding are referred to as *antagonists*.

DRUG-RESPONSE ASSESSMENT

In the prehospital setting the response to drug therapy often can be assessed by observing the effect of the drug on specific physical findings. Examples include monitoring blood pressure after administration of an antihypertensive medication and assessing pain relief after administration of an analgesic.

Each drug has its own characteristic rate of absorption, distribution, biotransformation, and excretion. Thus the effectiveness of some drugs cannot be monitored solely by the patient's response. For example, medications such as theophylline, ***digoxin*** (Lanoxin), and ***phenytoin*** (Dilantin) must reach a certain concentration at the target site to achieve the desired effect. Tissue concentrations often are proportional to and can be estimated from drug levels in the blood determined by laboratory analysis. Therapeutic drug levels in the blood, or serum, generally indicate ranges in tissue drug concentration that produce the desired therapeutic response.

Plasma-level profiles (Box 13-11) demonstrate the relationship between the concentration of drug in the plasma and the effectiveness of the drug over time (Figure 13-5). These profiles depend on the rate of absorption, distribution, biotransformation, and excretion after drug administration.

The **therapeutic range** for most drugs is based on the concentration that provides the highest probability of response with the least risk of toxicity. The dosage (loading and maintenance) required to achieve a therapeutic concentration varies because of the previously described factors that influence the actions of drugs: age, body mass, gender, pathological state, and genetic and psychological factors. In most patients, doses in the therapeutic range have a high probability of producing the desired effect and a low probability of toxicity. However, some patients fail to respond to doses in the therapeutic range. Still others may develop drug toxicity.

BOX 13-11 Plasma-Level Profile Terms

Duration of action: The period from onset of drug action to the time when a drug effect is no longer seen
Loading dose: A bolus of a drug given initially to attain a therapeutic plasma concentration rapidly
Maintenance dose: The amount of drug necessary to maintain a steady therapeutic plasma concentration
Minimum effective concentration: The lowest plasma concentration that produces the desired drug effect
Onset of action or latent period: The interval between the time a drug is administered and the first sign of its effect
Peak plasma level: The highest plasma concentration attained from a dose
Termination of action: The point at which the effect of a drug is no longer seen
Therapeutic range: The range of plasma concentrations most likely to produce the desired drug effect with the least likelihood of toxicity (the range between minimum effective concentration and toxic level)
Toxic level: The plasma concentration at which a drug is likely to produce serious adverse effects

BIOLOGICAL HALF-LIFE

The rate of biotransformation and excretion of a drug determines its biological half-life. The *biological half-life* is defined as the time it takes to metabolize or eliminate 50% of a drug in the body. For example, a 100-mg injection of a drug is given. Its half-life is 4 hours. Thus 50 mg will be eliminated in the first 4 hours, 25 mg (half of the remaining 50 mg) will be eliminated in the second 4 hours, and so on. A drug is considered to be eliminated from the body after five half-lives have passed.

CRITICAL THINKING

Adenosine (Adenocard) is an intravenous antidysrhythmic medicine. Adenosine has a half-life of only 1 to 3 seconds. How will this brief half-life influence the speed and frequency of administration of this drug?

The half-life of a drug is crucial when determining the frequency of administration. A drug that has a short half-life (e.g., 2 to 3 hours) must be administered more often to maintain a therapeutic range than a drug with a long half-life, such as 12 hours. The half-life of a drug may be lengthened considerably in persons with liver dysfunction or renal disorders. These and other disease processes may require a reduction in drug dosage, or the interval between doses may have to be lengthened.

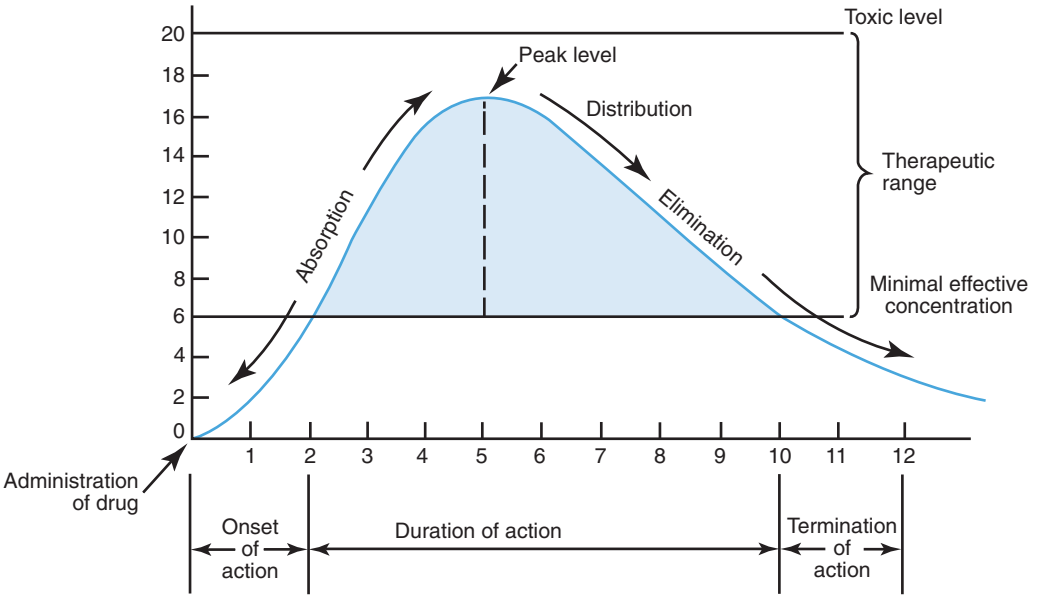

FIGURE 13-5 Plasma-level profile of a drug. (From McKenry LM, Tessier E, Hogan MA: *Mosby's pharmacology in nursing,* ed 22, St Louis, 2006, Mosby.)

THERAPEUTIC INDEX

The **therapeutic index** (TI) is a measurement of the relative safety of a drug. The index represents the ratio between two factors. The first factor is **lethal dose 50** (LD_{50}). This is the dose of a drug that is lethal in 50% of laboratory animals tested. The second factor is **effective dose 50** (ED_{50}). This is the dose that produces a therapeutic effect in 50% of a similar population. The therapeutic index is calculated as follows:

$$TI = \frac{LD_{50}}{ED_{50}}$$

A *wide* TI range indicates a drug is fairly safe. A *narrow* TI means the concentration range between effective levels of the drug and lethal levels of the drug is small. Therefore there is little room for error and it is easy to administer a toxic dose. The closer the ratio is to 1, the narrower the therapeutic index, and the greater the danger in administering the drug. In certain drugs, such as ***digoxin*** (Lanoxin), the difference between the effective dose and the lethal dose is small. In contrast, drugs such as ***naloxone*** (Narcan) have a wide margin between the effective dose (Figure 13-6).

DRUG INTERACTIONS

Many variables can influence drug interactions, including intestinal absorption, competition for plasma protein binding, biotransformation, action at the receptor site, renal excretion, and alteration of electrolyte balance. Not all drug interactions are dangerous; some may even be beneficial.

Some drug-drug interactions are clinically significant and can be dangerous. The paramedic should be aware of common drug-drug interactions. In addition, the paramedic should seek medical direction before giving drugs concurrently. (See the Emergency Drug Index.) The following drugs are associated with clinically significant drug-drug interactions:

- Blood thinners
- Tricyclic antidepressants (TCAs)
- Monoamine oxidase (MAO) inhibitors
- Amphetamines
- Digitalis glycosides
- Diuretics
- Antihypertensives

Other factors that can influence drug interactions include the following:

- Drug-induced malabsorption of food and nutrients
- Food-induced malabsorption of drugs
- Enzyme alterations that affect the metabolism of food or drugs
- Alcohol consumption
- Cigarette smoking that affects drug metabolism or excretion
- Food-initiated alteration of drug excretion

NOTE
Grapefruit and its juice can boost blood levels of some drugs as much as 1000%. This occurs through liver enzyme inhibition. Emergency drugs that can be affected include verapamil (Isoptin) and midazolam (Versed).

Finally, some drugs are incompatible with each other. For example, ***calcium chloride*** will precipitate (or crystallize) when mixed with ***sodium bicarbonate.***

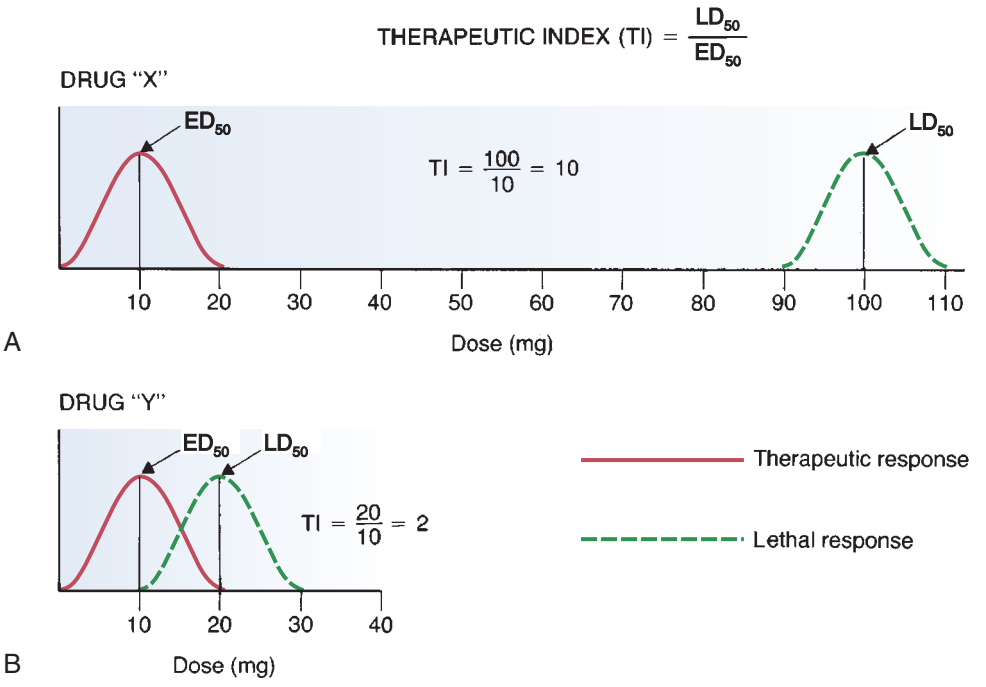

FIGURE 13-6 Plasma-level profile of a drug. (From Lehne R: *Pharmacology for nursing care,* ed 7, St Louis, 2009, Elsevier.)

DRUG FORMS, PREPARATIONS, AND STORAGE

Drugs and drug preparations are available in many forms (Box 13-12). Each one has specific indications, advantages, and disadvantages. These preparations are explained throughout the chapter and in the Emergency Drug Index.

Certain rules should guide the manner in which drugs are secured, stored, distributed, and justified. The paramedic should follow agency protocol and also local and state regulations. EMS personnel must be aware that temperature, light, moisture, and shelf life can affect drug potency and effectiveness.

DRUG PROFILES AND SPECIAL CONSIDERATIONS IN DRUG THERAPY

A paramedic should be familiar with the drug profiles of any drug he or she administers. Not all aspects of drug profiles can be committed to memory. Thus the paramedic should make regular use of pharmacology references (e.g., handbooks and pocket guides) and seek medical direction as needed. Paramedics are legally, morally, and ethically responsible for safe and effective drug administration (see Chapter 14). As part of the professional practice of patient management, paramedics must do the following:

- Use correct precautions and techniques when administering medications.
- Observe and document the effects of drugs.
- Be current in their knowledge base regarding changes in trends in pharmacology.
- Establish and maintain professional relationships with other members of the health care team.
- Understand pharmacodynamics of the drugs they administer.
- Carefully evaluate patients to identify drug indications and contraindications.
- Take a drug history from patients that includes the following information:

  Prescribed medications (name, strength, daily dosage)
  Over-the-counter medications
  Vitamins
  Alternative drug therapies (e.g., homeopathic medicines and herbal medicines)
  Any drug allergies or adverse drug reactions
- Strictly adhere to standing orders or protocols for drug administration or consult with online medical direction.

The components of a drug profile include the following:

Drug names: Usually the generic and trade names; may include chemical names

Classification: The group to which the drug belongs

Mechanism of action: The pharmacodynamic properties of a drug; the way in which a drug causes its effects

Indications: Conditions for which the drug is administered as approved by the FDA

BOX 13-12 Various Forms of Drug Preparations

Preparations for Oral Use

Liquids

Aqueous solution: substance dissolved in water and syrups
Aqueous suspension: solid particles suspended in liquid
Emulsion: fat or oil suspended in liquid with an emulsifier
Spirits: alcohol solution
Elixir: aromatic, sweetened alcohol and water solution
Tincture: alcohol extract of plant or vegetable substance
Fluid extract: concentrated alcoholic liquid extract of plant or vegetables
Extract: syrup or dried form of pharmacologically active drug, usually prepared by evaporating a solution

Solids

Capsule: soluble case (usually gelatin) that contains liquid, dry, or beaded drug particles
Tablet: compressed, powdered drugs in the form of a small disk
Troche or lozenge: medicated tablets that dissolve slowly in the mouth
Powder or granules: loose or molded drug substance for administration with or without liquids

Preparations for Parenteral Use

Ampule: sealed glass container for liquid injectable medication
Vial: glass container with rubber stopper for liquid or powdered medication
Cartridge or Tubex: single-dose unit of parenteral medication to be used with a specific injecting device

Intravenous Infusions (Suspended on Hanger at Bedside)

Flexible collapsible plastic bags (25 to 250 mL): used for continuous infusion of fluid replacement with or without medications
Intermittent intravenous infusions: usually secondary intravenous setup of a small plastic bag (25 to 250 mL) to which medication is added. The infusion runs as a "piggyback," hung separately from the primary intravenous infusion via a secondary administration tubing set usually for 20 to 120 minutes. The primary intravenous solution is run between medication doses or may be co-infused if the solutions are compatible
Heparin or saline lock: a port site for direct administration of intermittent intravenous medications without the need for primary intravenous solution

Preparations for Topical Use

Liniment: liquid suspension for lubrication that is applied by rubbing
Lotion: liquid suspension that can be protective, emollient, cooling, astringent, antipruritic, or cleansing
Ointment: semisolid medicine in a base for local protective, soothing, astringent, or transdermal application for systemic effects (nitroglycerin, scopolamine, estrogen)
Paste: thick ointment primarily used for skin protection
Plasters: solid preparations that are adhesive, protective, or soothing
Cream: emulsion that contains aqueous and oily bases
Aerosol: fine powder or solution in a volatile liquid that contains a propellant

Preparations for Use on Mucous Membranes

Drops for eyes, ears, or nose: aqueous solutions with or without gelling agent to increase retention time in the eye
Topical instillation of aqueous solution of medications: usually for topical action but occasionally for systemic effects (enema, douche, mouthwash, throat spray, gargle)
Aerosol sprays, nebulizers, and inhalers: aqueous solutions of medication delivered in droplet form to the target membrane, such as the bronchial tree (bronchodilators)
Nasal drugs: an alternative route for drugs with poor bioavailability and high-molecular-weight compounds such as peptides, steroids, and vaccines
Foam: powder or solution of medication in volatile liquid with propellant (vaginal foams for contraception)
Suppositories: usually medicinal substances mixed in a form but malleable base (cocoa butter to facilitate insertion into a body cavity [rectum or vagina])

Miscellaneous Drug Delivery Systems

Intradermal implants: pellets that contain a small deposit of medication and are inserted into a dermal pocket; they are designed to allow medication to leach slowly into tissue and usually are used to administer hormones such as testosterone or estradiol
Micropump system: small, external pump attached by belt or implanted that delivers medication via a needle in a continuous steady dose (insulin, anticancer chemotherapy, opioids)
Membrane delivery systems: drug-laden membranes are instilled into the eye to deliver a steady flow of medication (pilocarpine or corticosteroids)

Pharmacokinetics: How the body handles the drug over time; includes absorption, distribution, biotransformation, excretion, and onset and duration
Side/adverse effects: Untoward or undesired effects that may be caused by the drug
Dosages: The amount of drug to be administered
Routes of administration: How the drug is given
Contraindications: Conditions in which it may be harmful to administer the drug
Special considerations: How the drug may affect pediatric patients, geriatric patients, pregnant patients, and other special groups (described next)
Storage requirements: How the drug should be stored

Special Considerations in Drug Therapy

Special considerations in drug therapy must be taken into account when one is caring for pregnant patients, pediatric patients, and older adult patients. These considerations are

described next. They also are described throughout this text by subject matter and in the Emergency Drug Index.

SHOW ME THE EVIDENCE

This descriptive paper reviews 21,298 adverse drug events (ADEs) seen in emergency departments in 2004 and 2005. They found patients 65 years of age or older were more likely to experience ADEs and to need subsequent hospitalization as a result of the ADE. Drugs that were involved in ADEs most often included insulin, warfarin, antibiotics, and digoxin. On the whole, drugs that required frequent outpatient monitoring were implicated most often.

From Budnitz D, Pollock D, Weidenbach K et al: Emergency department surveillance for adverse drug events, *JAMA* 296(15):1858-1866, 2006.

PREGNANT PATIENTS

Before administering any drug to a pregnant patient, the paramedic should consider the expected benefits and the possible risks to the fetus. Drugs given to a pregnant patient may cross the placental barrier and harm the fetus or may be communicated to a newborn during breastfeeding. The FDA has established a scale to indicate drugs that may be harmful to a fetus during pregnancy (Box 13-13).

PEDIATRIC PATIENTS

Special considerations for administration of drugs to pediatric patients are presented here and throughout the text. Following is a summary of the pharmacokinetics that influence dosing principles in the neonate, infant, and pediatric populations.

Age. The effects of drugs are unpredictable among infants because of the variation in the development and maturation of the different organ systems.

CRITICAL THINKING

Drug doses vary for pediatric and neonatal patients. They are almost always related to weight. How can you ensure accuracy of dosing for these patients in critical situations when seconds count, even though you know the wrong dose calculation could be lethal?

Absorption. Drug absorption in infants and children follows the same basic principles as it does in adults. A factor that influences drug absorption is blood flow at the site of intramuscular or subcutaneous administration. Blood flow usually is determined by the patient's cardiovascular function. Certain physiological conditions might reduce blood flow to the muscle and subcutaneous tissue. These conditions include shock, vasoconstriction, and heart failure. The smaller muscle mass of the infant further complicates drug absorption because of diminished peripheral perfusion to these areas. For orally administered drugs, underlying gastrointestinal function may influence drug absorption.

BOX 13-13 Pregnancy Category Ratings for Drugs

Drugs have been categorized by the Food and Drug Administration according to the level of risk to the fetus. These categories are listed for each drug herein under Pregnancy Safety and are interpreted as follows[1]:

Category A: Controlled studies in women fail to demonstrate a risk to the fetus in the first trimester, and there is no evidence of risk in later trimesters; the possibility of fetal harm appears to be remote.

Category B: Either (1) animal reproductive studies have not demonstrated a fetal risk but there are no controlled studies in pregnant women or (2) animal reproductive studies have shown an adverse effect (other than decreased fertility) that was not confirmed in controlled studies on women in the first trimester, and there is no evidence of risk in later trimesters.

Category C: Either (1) studies in animals have revealed adverse effects on the fetus and there are no controlled studies in women or (2) studies in women and animals are not available. Drugs in this category should be given only if the potential benefit justifies the risk to the fetus.

Category D: There is positive evidence of human fetal risk, but the benefits for pregnant women may be acceptable despite the risk, as in life-threatening diseases for which safer drugs cannot be used or are ineffective. An appropriate statement must appear in the "Warnings" section of the labeling of drugs in this category.

Category X: Studies in animals or human beings have demonstrated fetal abnormalities, there is evidence of fetal risk based on human experience, or both; the risk of using the drug in pregnant women clearly outweighs any possible benefit. The drug is contraindicated in women who are or may become pregnant. An appropriate statement must appear in the "Contraindications" section of the labeling of drugs in this category.

Liquids and suspensions disperse quickly in gastrointestinal fluids. Thus they are more readily absorbed than tablet or capsule forms. Increases in peristalsis (e.g., diarrheal conditions) and lowered gastrointestinal enzyme activities tend to decrease overall absorption of orally or rectally administered medications.

Distribution. Most drugs are distributed in body water. Thus increases in total body water and extracellular volume can increase the volume of the distribution. Compared with adults, infants have proportionately higher volumes of total body water (70% to 75% compared with 50% to 60%). Infants also have a higher ratio of extracellular to intracellular fluid (40% compared with 30%); higher dosages of water-soluble drugs may be needed to have effective blood levels in the newborn.

Another key factor that affects drug distribution is drug binding to plasma proteins. In general, protein binding of drugs is reduced in the infant; therefore the concentration of free drug in plasma is increased. This can result in a

greater drug effect or toxicity. Regarding central nervous system effects, the blood-brain barrier in the infant is much less effective than in adults. This allows drugs greater access to this area.

Biotransformation. Various liver enzyme systems for metabolism generally mature unevenly. The infant therefore has a decreased ability to metabolize drugs. This predisposes the infant to developing toxicity from drugs metabolized by the liver. In addition, many drugs given to infants have slower renal clearance times and longer half-lives in the body. Thus the paramedic must adjust dosages based on age and weight.

Elimination. The glomerular filtration rate is much lower in newborns than in older infants, children, and adults. Therefore drugs eliminated through renal function are cleared from the body slowly in the first few weeks of life. Renal excretory mechanisms progress to maturity after 1 year of age. Before that age, excretion of some substances through the renal system may be delayed because of immaturity. This may result in higher serum levels and a longer duration of action than intended.

OLDER ADULT PATIENTS

Key changes in drug responses occur with age in most individuals. Factors associated with aging that significantly affect pharmacokinetics include the likelihood of multiple diseases requiring the use of several drugs (also referred to as *polydrug usage*). In addition, nutritional problems, decreased ability to metabolize drugs, and the possibility of decreased drug dosing compliance for a variety of reasons can influence the effects of drugs. This summary is meant to serve as a review of the pharmacokinetics that influence dosing principles in the older adult.

Age. Declines in the functional capacity of most major organ systems begin in young adulthood. These changes continue throughout life. Older adults do not lose specific function at a quicker rate than young and middle-aged adults; rather, they have less physiological reserves. Decreases in physiological function (glomerular filtration rate, cardiac function, maximal breathing capacity) generally are accepted as beginning by age 45. Decreased renal function has the greatest impact on medication administration and drug clearance.

Absorption. Little evidence exists of major changes in drug absorption with age. Yet conditions associated with age may alter the rate at which some drugs are absorbed. Examples of these conditions include altered nutritional habits, greater consumption of nonprescription drugs (e.g., antacids and laxatives), and changes in gastric emptying. The reduced production of gastric acid and slowed gastric motility may have an impact and may result in unpredictable rates of dissolution and absorption of weakly acidic drugs.

Distribution. Changes in body composition have been noted in the older adult. Such changes include reduced lean body mass, reduced total body water, and increased fat as a percentage of body mass. Levels of serum albumin—which binds many drugs, especially weak acids—also usually decline. This affects drug distribution; it decreases protein binding of drugs. This results in an increase in the amount of free drug in the circulation. Thus the ratio of bound to free drug in these patients may be significantly altered.

Biotransformation. The ability of the liver to metabolize drugs does not appear to decline consistently with age for all drugs. But disorders common with aging can impair liver function. One such example is congestive heart failure. Hepatic recovery from injury, such as that caused by alcohol or viral hepatitis, declines as well.

Certain drugs generally are believed to be metabolized more slowly in older adults. This is thought to be the case because of decreased liver blood flow. This decrease may lead to drug accumulation and toxicity. The paramedic must use caution when administering repeated doses of a medication that is metabolized primarily in the liver (e.g., ***lidocaine*** [Xylocaine]) to a patient with a history of liver disease. Older patients with severe nutritional deficiencies also may have impaired hepatic function.

Elimination. Renal function is the most critical factor for clearance of most drugs from the body. A natural reduction in renal function occurs with aging and usually is caused by loss of functioning nephrons and a decrease in blood flow. Both of these result in a decreased GFR. A decrease in renal function caused by decreases in renal blood flow also may occur because of congestive heart failure. The practical result of renal impairment is a prolongation of the half-life of many drugs and the possibility of accumulation to toxic levels. Other reversible conditions (e.g., dehydration) can cause further reduction in renal clearance of drugs.

Drug Administration Problems. Older adults commonly do not comply with their drug therapy. Noncompliance may be intentional or unintentional on their part but rarely affects the administration of emergency drugs. Still, the paramedic must be familiar with the most common factors that contribute to drug administration problems in older adults. This is crucial because noncompliance or errors may be a factor in the patient's condition. Following are some common causes of noncompliance and medication errors:

- The expense of drugs may lead to noncompliance in patients with fixed incomes. Older patients may not take prescribed medications routinely or may be unwilling to receive medications in emergency situations.
- Noncompliance in taking prescribed medications may result from forgetfulness or confusion, especially if the patient has several prescriptions and different dosing intervals.
- Older patients may forget instructions on the need to complete medication because symptoms have disappeared. Disappearance of symptoms often is regarded by the patient as the best reason to stop the therapy.
- Errors in self-administered medications may result from physical disabilities such as arthritis or visual impairment.

- Noncompliance may be deliberate. A patient may be opposed to taking a drug because of past experiences. A careful drug history is especially important when caring for older adults. The paramedic should remember that a patient has the right to refuse medication.

SECTION THREE
Drugs That Affect the Nervous System

REVIEW OF ANATOMY AND PHYSIOLOGY

The actions of many drugs depend on which branch of the autonomic nervous system they affect and whether the branch is stimulated or inhibited by drug therapy. The following is a discussion of the anatomy and physiology of the nervous system as they pertain to pharmacology (Box 13-14).

As described in Chapter 10, the *central nervous system* (CNS) consists of the brain and spinal cord. The CNS serves as the collection point for nerve impulses (Figure 13-7). The *peripheral nervous system* consists of cranial and spinal nerves and all their branches (those nerves outside the CNS). The peripheral nervous system connects all parts of the body to the CNS. The *somatic nervous system* controls functions that are under conscious, voluntary control such as skeletal muscles and sensory neurons of the skin. The *autonomic nervous system,* comprised mostly of motor nerves, controls functions of involuntary smooth muscles, cardiac muscles, and glands. Four types of nerve fibers are found in most nerves:

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 171-177.

1. *Visceral afferent* (sensory) *fibers,* which convey impulses from the internal organs to the CNS
2. *Visceral efferent* (motor) *fibers,* which convey impulses from the CNS to the internal organs, glands, and the smooth and cardiac (involuntary) muscles
3. *Somatic afferent* (sensory) *fibers,* which convey impulses from the head, body wall, and extremities to the CNS
4. *Somatic efferent* (motor) *fibers,* which convey impulses from the CNS to the striated (voluntary) muscles

Simply put, the peripheral (sensory) nervous system receives stimuli from the body. The CNS interprets these

BOX 13-14 Emergency Drugs: Nervous System

Atropine
Diazepam (Valium)
Dopamine (Intropin)
Epinephrine (Adrenalin)
Etomidate (Amidate)
Fentanyl (Sublimaze)
Hydromorphone (Dilaudid)
Lorazepam (Ativan)
Magnesium sulfate
Midazolam (Versed)
Morphine (Astramorph/PF)
Naloxone (Narcan)
Succinylcholine (Anectine)

stimuli. The peripheral (motor) nervous system initiates responses to the stimuli. Together the visceral afferent and visceral efferent nerve fibers form the autonomic nervous system. In contrast, the somatic afferent and somatic efferent nerve fibers form the somatic nervous system. Thus the autonomic nervous system and the somatic nervous system can be regarded as subdivisions of the peripheral nervous system (Box 13-15).

Autonomic Division of the Peripheral Nervous System

The autonomic division of the peripheral nervous system provides almost every organ with a double set of nerve fibers: *sympathetic* (also known as **adrenergic**) and *parasympathetic* (also known as **cholinergic**). The cell bodies of the neurons in these two divisions are located in different areas of the CNS. They also exit the spinal cord at different levels. The sympathetic fibers exit from the thoracic and lumbar regions of the spinal cord. The parasympathetic fibers exit from the cranial and sacral portions of the spinal cord.

The sympathetic and parasympathetic systems generally work as *physiological antagonists* on **effector organs.** That is, one division carries impulses that inhibit a certain function. The other division usually carries impulses that augment that function. As a rule, the sympathetic system prepares the body for vigorous muscular activity, stress, and emergencies (fight or flight). The sympathetic nervous system tends to affect widespread areas of the body for sustained periods of time. In contrast, the parasympathetic system lowers muscular activity, operates during nonemergency situations, conserves energy, and produces selective and localized responses of short duration. The sympathetic and parasympathetic systems operate at the same time. Yet one usually has more dominant effects at any given time.

Autonomic innervation by the sympathetic and parasympathetic nervous systems may be viewed as involving a two-neuron chain. This chain exists in a series between the CNS and the effector organs. This two-neuron chain is composed of a *preganglionic neuron,* located in the CNS, and a *postganglionic neuron,* located in the periphery (Figure 13-8). The area that serves as a functional junction between these two neurons is known as a *synapse*. The preganglionic fibers pass between the CNS and the nerve cell bodies in the peripheral nervous system (ganglia). The postganglionic fibers pass between the ganglia and the effector organ. Many of the sympathetic ganglia lie close to the spinal cord. Others lie about midway between the spinal cord and the effector organ. The parasympathetic ganglia lie close or within the walls of the effector organ. The difference in location of the ganglia in these two divisions is the anatomical reason for the widespread responses caused by the sympathetic division versus the localized responses caused by the parasympathetic division.

BOX 13-15 Organization of the Nervous System

Central Nervous System	Peripheral Nervous System
Brain	Cranial nerves
Spinal cord	Visceral afferent nerve fibers
	Visceral efferent nerve fibers
	Somatic afferent nerve fibers
	Somatic efferent nerve fibers
Spinal nerves	Visceral afferent nerve fibers
	Visceral efferent nerve fibers
	Somatic afferent nerve fibers
	Somatic efferent nerve fibers

Neurochemical Transmission

Most neurons are separated electrically from each other. Because of this separation, the fibers communicate by way of **neurotransmitters.** These are chemicals that are released from one neuron at the presynaptic nerve fiber. These neurotransmitters then cross the synapse where they may be accepted by the next neuron at a specialized site called a

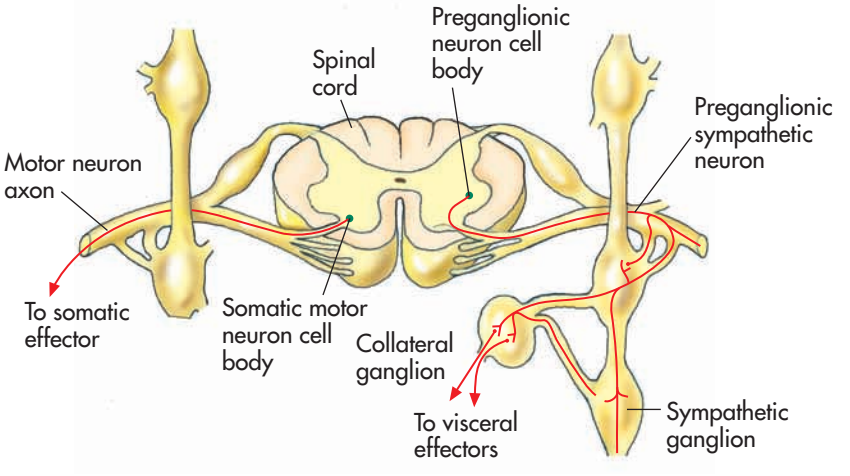

FIGURE 13-8 Autonomic conduction pathways.

receptor. (Neurotransmitters bind only to specific receptors on the postsynaptic membranes that recognize them.) The neurotransmitter then is deactivated or taken up into the presynaptic neuron.

In the sympathetic and parasympathetic divisions, the neurotransmitter for the preganglionic fiber at the junction between the preganglionic fiber and the synapse is **acetylcholine.** The neurotransmitter at the junction between the parasympathetic postganglionic fiber and the effector cell is also acetylcholine. Fibers that release acetylcholine are known as *cholinergic fibers*. All preganglionic neurons of the autonomic division and all postganglionic neurons of the parasympathetic division are cholinergic.

NOTE
All preganglionic nerves use the same neurotransmitter: acetylcholine.

The neurotransmitter between the sympathetic postganglionic fiber and the effector cell is **norepinephrine.** This chemical is a member of the catecholamine family. Fibers that release norepinephrine are known as *adrenergic fibers*. (This is a term derived from *noradrenaline,* the British name for norepinephrine.) Most postganglionic neurons of the sympathetic division are adrenergic; that is, they release norepinephrine. However, a few are cholinergic. The actions of the autonomic nervous system depend on the interaction between the neurotransmitter released by the ganglionic cells and the receptor effector cells. For example, stimulation of the sympathetic nerves causes excitatory effects in some organs and inhibitory effects in others. Likewise, parasympathetic stimulation causes excitation in some organs but inhibition in others.

NOTE
Two different neurotransmitters exist for postganglionic neurons. All parasympathetic postganglionic neurons release acetylcholine onto their target tissue. Most sympathetic postganglionic neurons release norepinephrine onto their target tissue.

The parasympathetic and sympathetic systems function continuously. They innervate many of the same organs at the same time. Thus the opposing actions of the two systems balance one another. (Most organs, however, are controlled predominantly by one or the other of the two systems.) As previously stated, the sympathetic system usually dominates during stressful events. The parasympathetic system is most active during periods of emotional and physical calmness.

Transmission of Nerve Impulses in the Autonomic Nervous System

Both branches of the autonomic nervous system have multiple receptors. The variety among neurotransmitters and receptors accounts for the differences in response to stimulation of sympathetic and parasympathetic nerves (excitatory or inhibitory).

The parasympathetic nervous system has nicotinic and muscarinic receptors (Figure 13-9). **Nicotinic receptors** (stimulated by nicotine) are found at the neuromuscular junctions of skeletal muscles. They also are found on the postganglionic neurons of the parasympathetic nervous system. **Muscarinic receptors** (stimulated by the mushroom poison muscarine) are found at the neuromuscular junction of cardiac and smooth muscle. They also are found on glands and on the postganglionic neurons of the sympathetic nervous system. Drugs that can activate nicotinic receptors typically do not activate muscarinic receptors. The difference between nicotinic and muscarinic receptors is crucial in drug therapy. For example, when acetylcholine binds to nicotinic receptors, an excitatory response occurs. When acetylcholine binds to muscarinic receptors, it results in excitation or inhibition. This depends on the target tissue in which the receptors are found (Table 13-3). When acetylcholine binds to muscarinic receptors in cardiac muscle, the heart rate slows. When it binds to muscarinic receptors in smooth muscle cells of the gastrointestinal tract, the rate and amplitude of contraction increase. ***Atropine*** blocks muscarinic but not nicotinic receptor sites. (Thus ***atropine*** affects the heart rate but does not cause paralysis.) A drug such as curare (a nicotinic receptor blocker), however, causes paralysis.

NOTE
The two types of cholinergic receptors are nicotinic receptors and muscarinic receptors. Nicotinic responses are of *fast onset and short duration* and are excitatory. Nicotinic receptors are associated with preganglionic neurons of both branches of the autonomic nervous system. Muscarinic receptors are of *slow onset and long duration* and may be excitatory or inhibitory. These receptors are associated with the neuromuscular junction.

CRITICAL THINKING
Imagine that your patient has eaten some poisonous mushrooms containing muscarine. What signs or symptoms related to pulse rate would you expect? What signs or symptoms related to gastrointestinal tract activity should be evident? Lastly, what signs or symptoms related to pupil diameter should be present?

For the sympathetic (adrenergic) nervous system, the major receptor types belong to two structural categories. These are the **alpha-adrenergic receptors** and the **beta-adrenergic receptors** (and their subgroups, described in the following text). Norepinephrine binds to and activates both types of receptor molecules. Yet norepinephrine has more affinity for alpha receptors. The hormone epinephrine is produced by the adrenal medulla and is classified as an adrenergic substance. Epinephrine has nearly equal

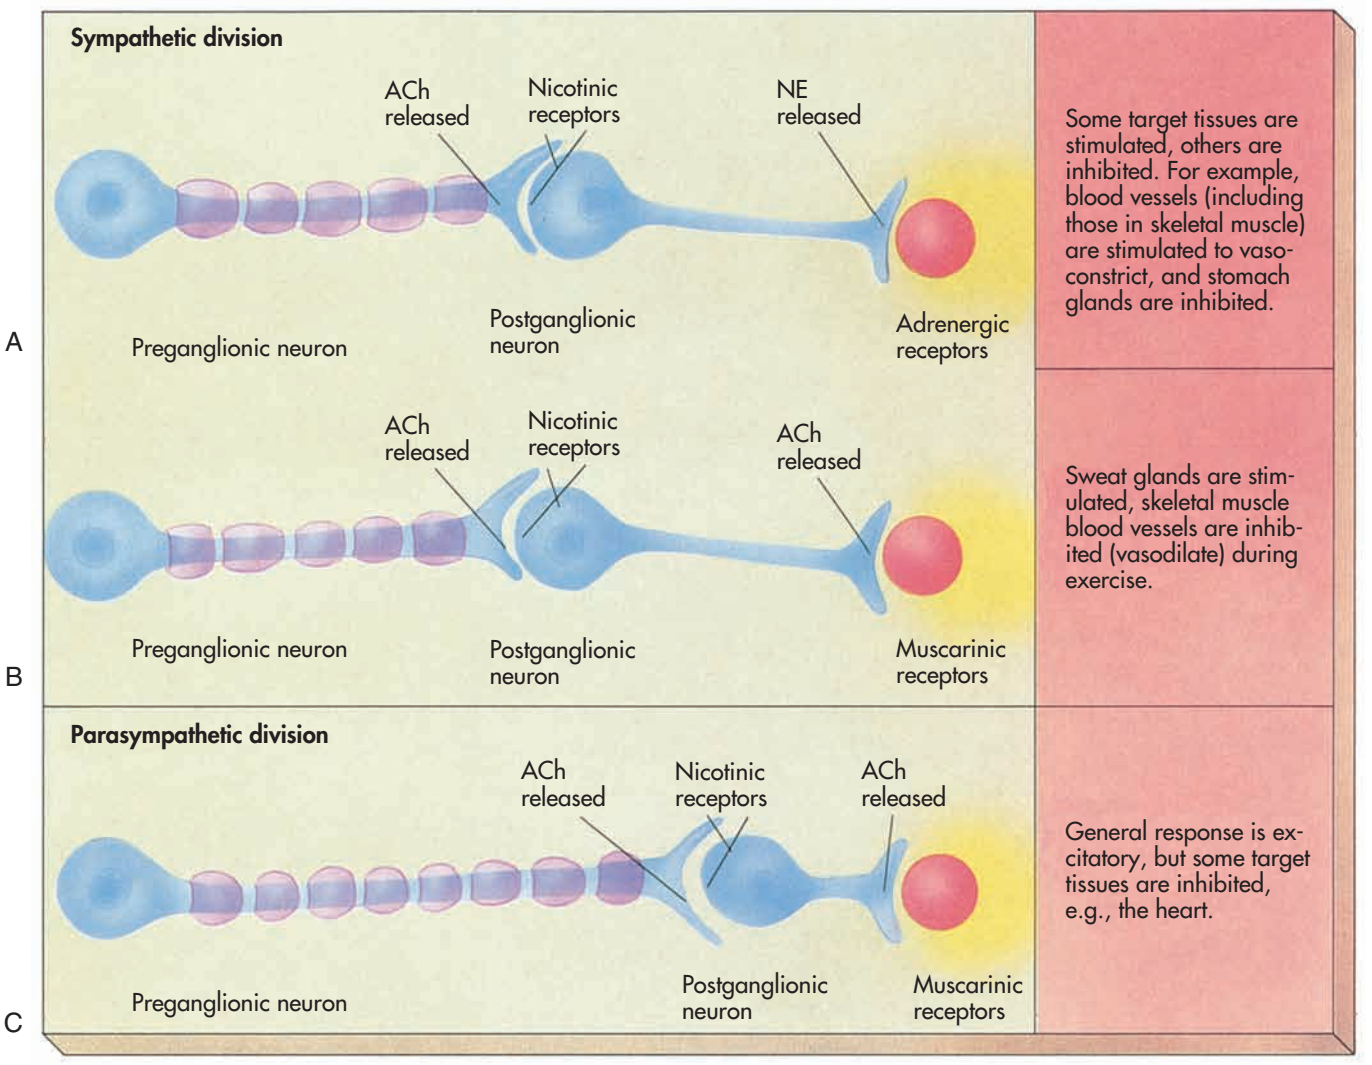

FIGURE 13-9 Location of the nicotinic, muscarinic, and adrenergic receptors in the autonomic nervous system. Nicotinic receptors are found on the cell bodies of sympathetic and parasympathetic postganglionic cells in the autonomic ganglia. **A,** Adrenergic receptors are found in most target tissues innervated by the sympathetic division. **B,** Some sympathetic target tissues have muscarinic receptors. **C,** All parasympathetic target tissues have muscarinic receptors. *ACh,* Acetylcholine; *NE,* norepinephrine.

affinity for both receptors. In tissues containing alpha- and beta-receptor cells, one type is more abundant. As a result, that type has a predominant effect. Both receptors can be excitatory or inhibitory. For example, beta receptors are stimulatory in cardiac muscle. Yet they are inhibitory in intestinal smooth muscle (Table 13-4).

NOTE
The two major types of adrenergic receptors are alpha and beta. Both receptors can be excitatory or inhibitory.

Drugs That Affect the Autonomic Nervous System

The nervous and endocrine systems are responsible for controlling and coordinating body functions. These two systems share three characteristics: a high level of integration in the brain, the ability to influence functions in distant regions of the body, and the extensive use of *negative feedback mechanisms* (described in Chapter 11). One main difference between the two systems is the mode of transmission of information.

TABLE 13-3 Sites for Muscarinic and Nicotinic Actions of Acetylcholine

Site	Muscarinic Actions*	Nicotinic Actions
Cardiovascular		
Blood vessels	Dilation	Constriction
Heart rate	Slowed	Increased
Blood pressure	Decreased	Increased
Gastrointestinal		
Tone	Increased	Increased
Motility	Increased	Increased
Sphincters	Relaxed	—
Glandular secretions	Increased salivary, lacrimal, intestinal, and sweat secretion	Initial stimulation and then inhibition of salivary and bronchial secretions
Other		
Skeletal muscle	—	Stimulation
Autonomic ganglia	—	Stimulation
Eye	Pupil constriction	—
	Decreased accommodation	—
Blocking agent	Atropine	Tubocurarine
Remarks	Above effects increase as dosage increases	Increased dosage inhibits effects and causes receptor blockade

*Usual sites for therapeutic effects.

LOOK AGAIN
Chapter 11: General Principles of Pathophysiology, pp. 238-240.

The endocrine system transmission is chiefly chemical. The information moves via blood-borne hormones. The hormones are not targeted for a specific organ. Instead, they diffusely affect many cells and organs at the same time. In contrast, the nervous system mainly relies on rapid electrical transmission of information over nerve fibers. Chemical impulses carry signals only between nerve cells and their effector cells in a localized manner, perhaps affecting only a few cells. (Drugs that affect the endocrine system are presented later in this chapter.)

CLASSIFICATIONS

The autonomic drugs mimic or block the effects of the sympathetic and parasympathetic divisions of the autonomic nervous system (Box 13-16). These drugs can be classified into four groups:

1. Cholinergic (*parasympathomimetic*) drugs, which mimic the actions of the parasympathetic nervous system
2. Cholinergic blocking (*parasympatholytic*) drugs, which block the actions of the parasympathetic nervous system
3. Adrenergic (*sympathomimetic*) drugs, which mimic the actions of the sympathetic nervous system or the adrenal medulla
4. Adrenergic blocking (*sympatholytic*) drugs, which block the actions of the sympathetic nervous system or adrenal medulla

Cholinergic Drugs. As described earlier, acetylcholine plays a key role in the parasympathetic and sympathetic divisions of the nervous system. Acetylcholine has two major effects in the nervous system: (1) a stimulant effect on the ganglia, adrenal medulla, and skeletal muscle (the nicotinic effect) and (2) stimulant effects at postganglionic nerve endings in cardiac muscle, smooth muscle, and glands (the muscarinic effect). Drugs that affect nicotinic or cholinergic receptor sites on autonomic ganglia are ganglionic-stimulating drugs (e.g., nicotine and nicotine gum) and ganglionic-blocking drugs (e.g., ***mecamylamine***).

Cholinergic drugs (choline esters) act directly with cholinergic receptors on postsynaptic membranes, or they act indirectly by inhibiting the enzyme that normally destroys acetylcholine. This inhibition results in an accumulation of acetylcholine. This in turn causes a longer and more intense

BOX 13-16 Anatomical and Functional Terms for the Autonomic Nervous System

The anatomical names and functional terms for the autonomic nervous system often are used interchangeably: sympathetic or adrenergic, and parasympathetic or cholinergic. The terms *parasympathomimetic* and *sympathomimetic* mean to mimic or to produce an effect similar to activation of either system. The words *parasympatholytic* and *sympatholytic* mean to block the normal effects seen with activation of either system. The term *anticholinergic* is synonymous with *parasympatholytic*.

Anatomical Name	Functional Term	Primary Neurotransmitter
Sympathetic	Adrenergic	Norepinephrine
Parasympathetic	Cholinergic	Acetylcholine

TABLE 13-4 Autonomic Innervation of Target Tissues

Organ	Effect of Sympathetic Stimulation*	Effect of Parasympathetic Stimulation*
Heart		
Muscle	Increased rate and force (b)	Slowed rate (c)
Coronary arteries	Dilation (b),† constriction (a)†	Dilation (c)
Systemic blood vessels		
Abdomen	Constriction (a)	None
Skin	Constriction (a)	None
Muscle	Dilation (b, c), constriction (a)	None
Lungs		
Bronchi	Dilation (b)	Constriction (c)
Liver	Release of glucose into blood (b)	None
Skeletal muscles	Breakdown of glycogen to glucose (b)	None
Metabolism	Increase of up to 100% (a, b)	None
Glands		
Adrenal glands	Release of epinephrine and norepinephrine (c)	None
Salivary glands	Constriction of blood vessels and slight production of thick, viscous secretion (a)	Dilation of blood vessels and thin, copious secretion (c)
Gastric glands	Inhibition (a)	Stimulation (c)
Pancreas	Inhibition (a)	Stimulation (c)
Lacrimal glands	None	Secretion (c)
Sweat glands		
Merocrine glands	Copious, watery secretion (c)	None
Apocrine glands	Thick, organic secretion (c)	None
Gut		
Wall	Decreased tone (b)	Increased motility (c)
Sphincter	Increased tone (a)	Decreased tone (c)
Gallbladder and bile ducts	Relaxation (b)	Contraction (c)
Urinary bladder		
Wall	Relaxation (b)	Contraction (c)
Sphincter	Contraction (a)	Relaxation (c)

Ciliary muscle	Relaxation for far vision (b)	Contraction for near vision (c)
Pupil	Dilation	Constriction (c)
Erector pili muscles	Contraction (a)	None
Blood	Increased coagulation (a)	None
Sex organs	Ejaculation (a)	Erection (c)

*(a), Mediated by alpha receptors; (b), mediated by beta receptors; (c), mediated by cholinergic receptors.
†Normally blood flow through coronary arteries increases as a result of sympathetic stimulation of the heart because of increased demand by cardiac tissue for oxygen. In experiments that isolate the coronary arteries, however, sympathetic nerve stimulation, acting through alpha receptors, causes vasoconstriction. The beta receptors are relatively insensitive to sympathetic nerve stimulation but can be activated by drugs.

response at various effector sites. Cholinergic drugs have little therapeutic value. For the most part, they are not thought of as emergency drugs. The main exception to this is ***physostigmine*** (Antilirium), which is an indirect-acting cholinergic drug. ***Physostigmine*** (Antilirium) may be used to manage extreme cases of poisoning resulting from atropine-type drugs (see Chapter 34). Indirect-acting cholinergic drugs are used to treat myasthenia gravis, a condition characterized by weakness of the skeletal muscles (described in Chapter 33). These drugs work to elevate the concentration of acetylcholine at myoneural junctions. This in turn increases muscle strength and function.

Cholinergic blocking (**anticholinergic**) agents have many uses in emergency medicine. These drugs work by blocking the muscarinic effects of acetylcholine. Thus they decrease the action of acetylcholine on its effector organ.

The best known cholinergic blocking drug used in emergency care is ***atropine.*** Atropine is a belladonna alkaloid that acts as a competitive antagonist. Atropine works by occupying muscarinic receptor sites. This action prevents or reduces the muscarinic response to acetylcholine. Large doses dilate the pupils, inhibit accommodation of the eyes, and increase the heart rate by blocking the cholinergic effects of the heart. Synthetic substitutes for ***atropine*** have been created to obtain only the antispasmodic effects of the drug. (For example, they may be used to treat gastric and duodenal ulcers.) These synthetic drugs include dicyclomine (Bentyl) and glycopyrrolate (Robinul).

Adrenergic Drugs. Adrenergic drugs are designed to produce activities like those of neurotransmitters. The three types of adrenergic agents are *direct acting, indirect acting,* and *dual acting* (direct and indirect).

Direct-Acting Drugs. Three naturally occurring catecholamines are present in the body: epinephrine, norepinephrine, and dopamine. Epinephrine acts mainly as an emergency hormone. Epinephrine is released by the adrenal medulla. Norepinephrine acts as a critical neurotransmitter of nerve impulses. Dopamine is a precursor of epinephrine and norepinephrine. Dopamine has a neurotransmitter role of its own in certain parts of the CNS. Examples of synthetic catecholamine drugs and the three endogenous catecholamines are ***epinephrine*** (Adrenalin), ***norepinephrine*** (Levophed), ***dopamine*** (Intropin), and ***dobutamine*** (Dobutrex).

Catecholamines depend on their ability to act directly with alpha and beta receptors. Two subgroups of **alpha receptors** have been identified. These are alpha$_1$ and alpha$_2$. *Alpha$_1$* **receptors** are postsynaptic receptors. They are located on the effector organs. The chief role of the alpha$_1$ receptor is to stimulate contraction of smooth muscle. In the vasculature, this results in an increase in blood pressure. *Alpha$_2$ receptors* are found on presynaptic and postsynaptic nerve endings. When stimulated, presynaptic receptors inhibit the further release of norepinephrine. Like alpha$_1$ receptors, alpha$_2$ postsynaptic receptors produce vasoconstriction to increase resistance in blood vessels and thus increase blood pressure.

Beta receptors are subdivided into beta$_1$ and beta$_2$ receptors based on their response to drugs. However, the division also follows anatomical distinctions. *Beta$_1$ receptors* are located mainly in the heart. *Beta$_2$ receptors* are located mainly in the bronchiolar and arterial smooth muscle. Beta receptors stimulate the heart; dilate bronchioles; dilate blood vessels in the skeletal muscle, brain, and heart; and aid in glycogenolysis (the breakdown of glycogen to glucose) (Table 13-5).

NOTE

Use of a memory aid to differentiate the physiological effects of beta receptors may be helpful: A person has one heart (beta$_1$ effects) and two lungs (beta$_2$ effects).

Norepinephrine acts mainly on alpha receptors. It causes almost pure vasoconstriction of the blood vessels. Epinephrine acts on alpha and beta receptors. It produces a mixture of vasodilation and vasoconstriction. This effect depends on the number of alpha and beta receptors present in the target tissue. The following are the most important alpha and beta activities in human beings:

1. Alpha activities
   - Vasoconstriction of arterioles in the skin and splanchnic area, resulting in a rise in blood pressure and peripheral shunting of blood to the heart and brain from the shifting of blood volume
   - Pupil dilation
   - Relaxation of the gut
2. Beta activities
   - Cardiac acceleration and increased contractility
   - Vasodilation of arterioles supplying the skeletal muscle
   - Bronchial relaxation
   - Uterine relaxation

Indirect-Acting and Dual-Acting Drugs. Indirect-acting adrenergic drugs act indirectly on receptors. They do this by triggering the release of the catecholamines norepinephrine and epinephrine. These chemicals then activate the alpha and beta receptors. Dual-acting adrenergic drugs have indirect and direct effects. An example of a drug in this group is ephedrine (ephedrine sulfate).

Adrenergic blocking agents may be classified into alpha- and beta-blocking drugs. Alpha-blocking drugs block the vasoconstricting effect of catecholamines. They are used in certain cases of hypertension. They also are used to help prevent necrosis when ***norepinephrine*** (Levophed) or ***dopamine*** (Intropin) has leaked, or extravasated, into the tissues. They have limited clinical application in the prehospital setting.

NOTE

All drugs with alpha effects should be administered through a secure intravenous line. This line should be well positioned in a large vein because of the possibility of extravasation and tissue necrosis.

Beta-blocking agents have greater clinical application. They often are used in emergency care. These drugs block beta receptors. They inhibit the action of beta receptors at the effector site. Beta-blocking agents are grouped into **selective beta-blocking agents** and **nonselective beta-blocking agents.** The selective blocking agents block beta$_1$ or beta$_2$ receptors. The nonselective beta-blocking agents block beta$_1$- and beta$_2$-receptor sites. Selective beta$_1$-blocking agents also are known as *cardioselective blockers* because they block the beta$_1$ receptors in the heart with minimal beta$_2$ activities in the lungs. Examples of important selective beta$_1$-blocking agents are ***metoprolol*** (Lopressor, Toprol-XL) and ***atenolol*** (Tenormin). These drugs are antihypertensives and antidysrhythmics. They are used in managing hypertension. They also are used in select patients with suspected myocardial infarction and high-risk unstable angina.

Nonselective beta-blocking agents inhibit beta receptors in the smooth muscle both of the bronchioles and of the blood vessels. Examples include the antianginal antihypertensives **nadolol** (Corgard) and ***propranolol*** (Inderal), and the antihypertensive ***labetalol*** (Normodyne, Trandate). (***Labetalol*** also has some alpha-blocking activity.)

TABLE 13-5 Actions of Autonomic Nervous System Neuroreceptors

Effector Organ or Tissue	Receptor	Adrenergic Effect	Cholinergic Effect
Eye, iris			
Radial muscle	α_1	Contraction (mydriasis)	—
Sphincter muscle		—	Contraction (miosis)
Eye, ciliary muscle	β_2	Relaxation for far vision	Contraction for near vision
Lacrimal glands	—	—	Secretion
Nasopharyngeal glands	—	—	Secretion
Salivary glands	α_1	Secretion of potassium and water	Secretion of potassium and water
	β	Secretion of amylase	—
Heart			
SA node	β_1	Increased heart rate	Decreased heart rate; vagus arrest
Atrial	β_1	Increased contractility and conduction velocity	Decreased contractility; shortened action potential duration
AV junction	β_1	Increased automaticity and propagation velocity	Decreased automaticity and propagation velocity
Purkinje system	β_1	Increased automaticity and propagation velocity	—
Ventricles	β_1	Increased contractility	—
Arterioles			
Coronary	α_1, β_2	Constriction, dilation	Dilation
Skin and mucosa	α_1, α_2	Constriction	Dilation
Skeletal muscle	α, β_2	Constriction, dilation	Dilation
Cerebral	α_1	Constriction (slight)	—
Pulmonary	α_1, β_2	Constriction, dilation	—
Mesenteric	α_1	Constriction	—
Renal	α_1, β_1, β_2,	Constriction, dilation	—
Salivary glands	α_1, α_2	Constriction	Dilation
Veins, systemic	α_1, β_2	Constriction, dilation	—
Lung			
Bronchial muscle	β_2	Relaxation	Contraction
Bronchial glands	α_1, β_2	Decreased secretion; increased secretion	Stimulation
Stomach			
Motility	α_1, β_2	Decreased (usually)	Increased
Sphincters	α_1	Contraction (usually)	Relaxation (usually)
Secretion	—	Inhibition (?)	Stimulation
Liver	α, β_2	Glycogenolysis and gluconeogenesis	Glycogen synthesis
Gallbladder and ducts	—	Relaxation	Contraction
Pancreas			
Acini	α	Decreased secretion	Secretion
Islet cells	α_2, β_2	Decreased secretion; increased secretion	—
Intestine			
Motility and tone	α_1, β_1, β_2	Decreased	Increased
Sphincters	α_1	Contraction (usually)	Relaxation (usually)
Secretion	α_2	Inhibition (?)	Stimulation
Adrenal medulla	—	—	Secretion of epinephrine and norepinephrine (nicotinic effect)
Kidney			
Renin secretion	α_1, β_1	Decreased; increased	—
Ureter			
Motility and tone	α_1	Increased	Increased
Urinary bladder			
Detrusor muscle	β_2	Relaxation (usually)	Contraction
Trigone and sphincter	α_1	Contraction	Relaxation
Sex organs, male	α_1	Ejaculation	Erection
Skin			
Pilomotor muscles	α_1	Contraction	—
Sweat glands	α_1	Localized secretion	Generalized secretion
Fat cells	α_2; $\beta_1(\beta_3)$	Inhibition of lipolysis; stimulation of lipolysis	—
Pineal gland	β	Melatonin synthesis	—

CRITICAL THINKING

Physicians usually will not prescribe a nonselective beta blocker such as propranolol (Inderal) for patients with a history of asthma. Explain why this is true.

Narcotic Analgesics and Antagonists

Narcotic analgesics relieve pain. Narcotic antagonists reverse the effects of some narcotic analgesics. Pain has two components. The first is the sensation of pain. This involves the nerve pathways and the brain. The second is the emotional response to pain. This may be a result of the individual's anxiety level, previous pain experience, age, gender, and culture. Box 13-17 lists and defines classifications of pain.

Opiates are drugs that contain or are extracted from opium. The term *opioid* refers to synthetic drugs. These drugs have pharmacological properties that are similar to those of opium or ***morphine.*** Morphine is the chief alkaloid of opium. Opioids work by binding with opioid receptors in the brain and other body organs. This alters the patient's perception of pain and the emotional response to a pain-causing stimulus. Opioid analgesics include ***morphine,*** codeine (methylmorphine), hydromorphone (Dilaudid), ***meperidine*** (Demerol), ***fentanyl*** (Duragesic, Sublimaze), methadone (Dolophine, Methadose), oxycodone (OxyContin, Percodan, Tylox, Percocet), hydrocodone (Lortab, Vicodin), and propoxyphene (Darvon, Dolene).

NOTE

Endorphins serve as the body's own supply of "opiates." Endorphins are produced by the pituitary gland and the hypothalamus during strenuous exercise, excitement, pain, and orgasm. They resemble the opiates in their abilities to produce analgesia by binding to opiate receptors, thereby blocking pain. They also produce a sense of well-being. Endorphins work as "natural pain relievers," whose effects may be enhanced by other medications.

BOX 13-17 Classifications of Pain

Acute pain: Pain sudden in onset that usually subsides with treatment (e.g., pain associated with acute myocardial infarction, acute appendicitis, renal colic, or traumatic injuries)

Chronic pain: Persistent or recurrent pain that is difficult to treat (e.g., pain that accompanies cancer and rheumatoid arthritis)

Referred pain: Visceral pain felt at a site distant from its origin (e.g., pain from a myocardial infarction felt in the arm)

Somatic pain: Pain arising from skeletal muscles, ligaments, vessels, or joints

Superficial pain: Pain arising from the skin or mucous membrane

Visceral pain: "Deep" pain arising from smooth musculature or organ systems that may be difficult to localize and is often described as dull or aching

Opioid analgesics may produce undesirable effects such as nausea and vomiting, constipation, urinary retention, orthostatic hypotension, respiratory depression, and CNS depression. Most of these effects can be overcome by careful administration and close patient monitoring.

Opioid antagonists block the effects of opioid analgesics by displacing the analgesics from their receptor sites. (Examples of such effects are opioid-induced respiratory depression and sedation.) ***Naloxone*** (Narcan), naltrexone (Trexan), and ***nalmefene*** (Revex) are opioid antagonists.

Opioid agonist-antagonist agents have analgesic and antagonist effects. They are thought to have pharmacokinetic and adverse effects similar to those of ***morphine.*** They may antagonize some opioid receptors competitively. Yet they may have varying degrees of agonist effect at other opioid receptor sites. Examples of these drugs include pentazocine (Talwin) and nalbuphine (Nubain). These drugs generally have a lower potential for creating dependency than opioid analgesics. In addition, withdrawal symptoms are not as severe as those of the opioid agonist drugs. They may initiate withdrawal symptoms in addicts.

Nonnarcotic Analgesics

Nonnarcotic analgesics act by a peripheral mechanism that interferes with local mediators released when tissue is damaged. These mediators stimulate nerve endings and they cause pain. When nonnarcotic analgesics are used, the nerve endings in damaged tissues are stimulated less often. This differs from the mechanism of narcotic analgesics that act at the level of the CNS. An example of a nonnarcotic analgesic is ***ketorolac*** (Toradol), a nonsteroidal antiinflammatory drug (NSAID) that exhibits analgesic activity. Another is tramadol (Ultram). Other nonnarcotic analgesics include cyclooxygenase (COX) inhibitors and oral NSAIDs such as ibuprofen (Advil), naproxen (Aleve), and acetaminophen (described later in this chapter).

CRITICAL THINKING

A nonnarcotic analgesic may be selected instead of a narcotic for a paramedic returning to work on the ambulance. Why?

Anesthetics

Anesthetic drugs are CNS depressants. They have a reversible action on nervous tissue. The three major types of anesthesia are general, regional, and local. *General anesthesia* is achieved by intravenous or inhalation routes and is the most common type of anesthesia used during surgery to induce unconsciousness. *Regional anesthesia* is obtained by injecting a local anesthetic drug. The drug is injected near a nerve trunk or at specific sites in a large region of the body (e.g., spinal block). *Local anesthesia* is achieved topically to produce a loss of sensation. Local anesthesia also can be achieved by injection to block an area surrounding an operative field, making it insensitive to pain (e.g., minor wound repair) (Box 13-18).

BOX 13-18 Examples of Anesthetics

Inhalation Anesthetics

Gases
Cyclopropane
Nitrous oxide; oxygen (Nitronox)

Volatile Liquids
Halothane (Fluothane)
Methoxyflurane (Penthrane)
Enflurane (Ethrane)
Isoflurane (Forane)
Sevoflurane (Ultane)
Desflurane (Suprane)

Intravenous Anesthetics

Ultrashort-Acting Barbiturates
Thiopental sodium (Pentothal)
Thiamylal sodium (Surital)
Methohexital sodium (Brevital Sodium)

Nonbarbiturates
Etomidate (Amidate)
Fentanyl (Sublimaze)
Sufentanil (Sufenta)
Alfentanil (Alfenta)
Propofol (Diprivan)

Dissociative Anesthetics
Ketamine (Ketalar)

Neuroleptic Anesthetics
Droperidol-fentanyl (Innovar injection)

Local Anesthetics

Topical
Benzocaine (Anbesol)
Ethyl chloride cocaine
Lidocaine (Xylocaine)
Tetracaine (Pontocaine)

Injectable
Lidocaine (Xylocaine)
Procaine (Novocain)

BOX 13-19 The Physiology of Sleep

Sleep can be viewed as a series of rhythms. Each has its own brain wave patterns. These rhythms can be divided into two major categories: rapid eye movement (REM) and non–rapid eye movement (non-REM). During sleep, a person moves through REM sleep. Then the person moves through four stages of non-REM sleep. Rapid eye movement, or active, sleep is the time of irregular body activity, vivid dreaming, and rapid eye movements. During REM sleep, the eyes move back and forth under the closed lids as they follow the action of a dream. The heart rate, blood pressure, and respirations may become irregular. During non-REM sleep, the person drifts out of wakeful awareness. The muscles relax, and the blood pressure, heartbeat, and breathing begin to decline. The brain sends signals to the arms, legs, and other large muscles to stop moving. At that point, "sleep paralysis" occurs. The first REM period lasts nearly 10 minutes. The whole cycle repeats itself usually four to five times each night. Each cycle lasts an average of 90 minutes. As the night continues, REM periods lengthen and non-REM periods shorten. The final REM period of the night may last as long as 1 hour.

Antianxiety and Sedative-Hypnotic Agents and Alcohol

Antianxiety and sedative-hypnotic agents and alcohol are presented together because of their similarities in pharmacological action. Antianxiety agents are used to reduce feelings of apprehension, nervousness, worry, or fearfulness.

Sedatives and hypnotics are drugs that depress the CNS, produce a calming effect, and help induce sleep (Box 13-19). The major difference between a sedative and a hypnotic is the degree of CNS depression induced by the agent. For example, a small dose of an agent administered to calm a patient is called a *sedative;* a larger dose of the same agent sufficient to induce sleep is called a *hypnotic*. Thus an agent may be a sedative or a hypnotic, depending on the dose used.

As stated before, alcohol has actions that are characteristic of sedative-hypnotic or antianxiety drugs. Alcohol is a major source of drug abuse and dependency.

Scattered throughout the brainstem is a group of nuclei, collectively called the *reticular formation*. The reticular formation and its neural pathways compose a system known as the *reticular activating system* (described in Chapter 10). This system is involved with the sleep-wake cycle. Through these pathways, the reticular activating system collects incoming signals from the senses and viscera. The system then processes and passes these signals to the higher brain centers. The reticular activating system determines the level of awareness to the environment. Thus the reticular activating system also governs actions and responses to the environment. Antianxiety and sedative-hypnotic agents and alcohol act by depressing this system.

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 171-173.

CLASSIFICATIONS

Two prototypical groups of drugs are used to treat anxiety and to induce sleep. These are the benzodiazepines and barbiturates, respectively. Benzodiazepines make up the drug class most often used today to treat anxiety and insomnia. Barbiturates compose an older drug class with many uses. These uses range from sedation to anesthesia.

Benzodiazepines. Benzodiazepines were introduced in the 1960s as antianxiety drugs. At present, they are among the most widely prescribed drugs in clinical medicine. This

is partly because of their wide therapeutic index. Mortality and morbidity from an oral overdose is rare, unless taken with other CNS depressants, such as alcohol.[9] Benzodiazepines are thought to work by binding to specific receptors in the cerebral cortex and limbic system. (These systems together govern emotional behavior.) These drugs are highly lipid soluble and are distributed widely in the body tissues. They also are highly bound to plasma protein, usually more than 80%. Benzodiazepines have four actions: anxiety reducing, sedative-hypnotic, muscle relaxing, and anticonvulsant. All benzodiazepines are schedule IV drugs because of their potential for abuse. Commonly prescribed benzodiazepines are alprazolam (Xanax), clonazepam (Klonopin), ***diazepam*** (Valium), flurazepam (Dalmane), ***midazolam*** (Versed), ***lorazepam*** (Ativan), and temazepam (Restoril).

CRITICAL THINKING

Consider that you are preparing to reduce a dislocated shoulder. Why would a benzodiazepine be preferred over a narcotic?

NOTE

Flumazenil (Romazicon) is a specific benzodiazepine receptor antagonist. Flumazenil has been shown to be effective in reversing benzodiazepine-induced sedation and coma[10] (see Chapter 34 and the Emergency Drug Index).

Barbiturates. Barbiturates were once the most commonly prescribed class of medications for sedative-hypnotic effects. However, they virtually have been replaced by the benzodiazepines. Barbiturates are divided into four classes according to their duration of action: *ultrashort acting, short acting, intermediate acting,* and *long acting.* The differences in onset and duration of action depend on their lipid solubility and protein-binding properties. Ultrashort-acting barbiturates commonly are used as intravenous anesthetics. These drugs act rapidly and can produce a state of anesthesia in a few seconds. An example of an ultrashort-acting barbiturate is thiopental sodium (Pentothal).

Short-acting barbiturates produce an effect in a short time (10 to 15 minutes). They also peak over a short period (3 to 4 hours). This class of drugs rarely is used to treat insomnia; it more often is used for preanesthesia sedation and in combination with other drugs for psychosomatic disorders. Examples include pentobarbital (Nembutal) and secobarbital (Seconal).

Intermediate-acting barbiturates have an onset of 45 to 60 minutes. They peak in 6 to 8 hours. Short-acting and intermediate-acting barbiturates produce similar patient responses. Examples of intermediate-acting barbiturates include amobarbital (Amytal) and butabarbital (Butisol).

Long-acting barbiturates require more than 60 minutes for onset. They peak over 10 to 12 hours. These agents are used to treat epilepsy and other chronic neurological disorders (see Chapter 25). They also are used to sedate patients with severe anxiety. Examples of long-acting barbiturates include mephobarbital (Mebaral) and phenobarbital (Luminal).

Miscellaneous Sedative-Hypnotic Drugs. The previously discussed drug classes do not include all of the antianxiety and sedative-hypnotic drugs. In fact, a number of other antianxiety and sedative-hypnotic drugs do not fall into these classes. These agents are more similar to barbiturates than benzodiazepines because they are generally shorter acting. Examples of miscellaneous drugs with antianxiety and sedative-hypnotic effects are chloral hydrate (Noctec), eszopiclone (Lunesta), and zolpidem (Ambien). In addition to these drugs, antihistamines such as hydroxyzine (Vistaril, Atarax) have pronounced sedative effects. Etomidate (Amidate) is another nonbarbiturate, hypnotic anesthetic used for premedication for tracheal intubation and cardioversion.

Alcohol Intake and Behavioral Effects

Alcohol is a general CNS depressant that can produce sedation, sleep, and anesthesia. In addition, alcohol enhances the sedative-hypnotic effects of other drug classes, including all general CNS depressants, antihistamines, phenothiazines, narcotic analgesics, and tricyclic antidepressants. If alcohol is taken with other drugs, this enhancement could result in coma or death. Blood alcohol is measured in milligrams per deciliter (mg/dL). Characteristic behavioral effects can be predicted based on the amount of alcohol consumed and blood alcohol levels. Behavioral effects associated with alcohol intake are described further in Chapter 34.

Anticonvulsants

Anticonvulsant drugs are used to treat seizure disorders. The most notable of these disorders is epilepsy. Epilepsy is a neurological disorder characterized by a recurrent pattern of abnormal neuronal discharges within the brain. These discharges result in a sudden loss or disturbance of consciousness, sometimes associated with motor activity, sensory phenomena, or inappropriate behavior. Epilepsy is estimated to occur in 0.5% to 1% of the population. In 50% of these cases, the cause is unknown (primary or idiopathic epilepsy). Secondary epilepsy is epilepsy that can be traced to trauma, infection, a cerebrovascular disorder, or some other illness. (Epilepsy is discussed further in Chapter 25.)

Anticonvulsant drugs work by depressing the excitability of neurons that fire to initiate the seizure. These drugs also suppress the neurons responsible for the spread of the seizure discharge. Anticonvulsants are presumed to modify the ionic movements of sodium, potassium, or calcium across the nerve membrane. Thus they reduce the response to incoming electrical or chemical stimulation. Benzodiazepines also stimulate major inhibitory neurotransmitters in the CNS. Many patients need drug therapy throughout their lives to control seizure disorders.

Several drugs are available for the control of seizure disorders. The choice of drug depends on the type of seizure disorder (*generalized, partial,* or *status;* described in Chapter 25). The choice of drug also depends on the patient's tolerance and response to the prescribed medication. Box 13-20 presents classes of anticonvulsant drugs.

Central Nervous System Stimulants

Central nervous system stimulants are classified by where they exert their major effects in the nervous system: on the cerebrum, on the medulla and brainstem, or in the hypothalamic limbic regions. All CNS stimulants work to increase excitability by blocking activity of inhibitory neurons or their respective neurotransmitters or by enhancing the production of the excitatory neurotransmitters. Some of the more common CNS stimulant drugs are anorexiants and amphetamines.

ANOREXIANTS

Anorexiants are appetite suppressants. They are used to treat obesity. They work by producing a direct stimulant effect on the hypothalamic and limbic regions. They perhaps have this effect on other areas of the nervous system as well. Examples of anorexiants include phendimetrazine (Plegine) and mazindol (Mazanor, Sanorex).

A new class of drugs (gastrointestinal lipase inhibitors, or fat blockers) block the absorption of about 30% of dietary fat. These drugs sometimes are used to manage obesity along with a reduced-calorie diet. An example of a gastrointestinal lipase inhibitor is orlistat (Xenical).

BOX 13-20 Classes of Anticonvulsant Drugs

Barbiturates
Phenobarbital (Luminal)

Benzodiazepines
Clonazepam (Klonopin)
Diazepam (Valium)
Lorazepam (Ativan)

Hydantoins
Fosphenytoin (Cerebyx)
Phenytoin (Dilantin)

Succinimides
Ethosuximide (Zarontin)
Zonisamide (Zonegran)

Other
Carbamazepine (Tegretol)
Divalproex (Depakote)
Gabapentin (Neurontin)
Lamotrigine (Lamictal)
Magnesium sulfate
Topiramate (Topamax)
Valproic acid (Depakene)
Levetiracetam (Keppra)

From McKenry L, Leda M: *Mosby's pharmacology in nursing*, ed 22, St Louis, 2005, Mosby.

DID YOU KNOW?

At one time, a two-drug combination of fenfluramine and phentermine (Fen-Phen) was used to manage obesity. The combination was withdrawn from the market in 1997. It was found to have serious complications. These included potentially fatal primary pulmonary hypertension and valvular heart disease.

AMPHETAMINES

Amphetamines stimulate the cerebral cortex and reticular activating system. This stimulation increases alertness and responsiveness to environmental surroundings. Amphetamines mainly are used to treat *attention deficit hyperactivity disorder* (ADHD), *attention deficit disorder* (ADD), and *narcolepsy*. For the most part, ADHD is seen in children and adolescents and is characterized by a short attention span and impulsive behavior. (ADHD and ADD are described further in Chapter 35.)

Individuals with narcolepsy experience excessive drowsiness, sudden sleep attacks during daytime hours, and sometimes sleep paralysis. Medications used to treat these disorders include methamphetamine (Desoxyn), amphetamine-mixed salts (Adderall), and dextroamphetamine tablets and elixir. Nonamphetamine CNS stimulants used to treat ADHD and ADD include methylphenidate (Ritalin, Concerta), atomoxetine (Strattera), and pemoline (Cylert). Paradoxically, amphetamines and other stimulants have a calming effect on persons with ADHD. Likely, the drugs achieve this effect by increasing neurotransmitter levels of dopamine.

Psychotherapeutic Drugs

Psychotherapeutic drugs include antipsychotic agents, antidepressants, and lithium. These drugs are used to treat psychoses and affective disorders, especially schizophrenia, depression, and mania (see Chapter 35).

CENTRAL NERVOUS SYSTEM AND EMOTIONS

The neurotransmitters acetylcholine, norepinephrine, dopamine, serotonin, and monoamine oxidase have a major effect on emotion (Figure 13-10). Alterations in the levels of these chemicals are linked to changes in mood and behavior. Drug therapy alleviates symptoms by temporarily modifying unwanted behavior.

NOTE

Acetylcholine is released from central neural tissue into the cerebrospinal fluid during activity. Norepinephrine and dopamine have widespread inhibitory effects. They influence functions such as sleep and arousal, affect, and memory. Serotonin levels affect mood and behavior. Monoamine oxidase is an enzyme that inactivates dopamine and serotonin, both of which are produced during intense emotional states.

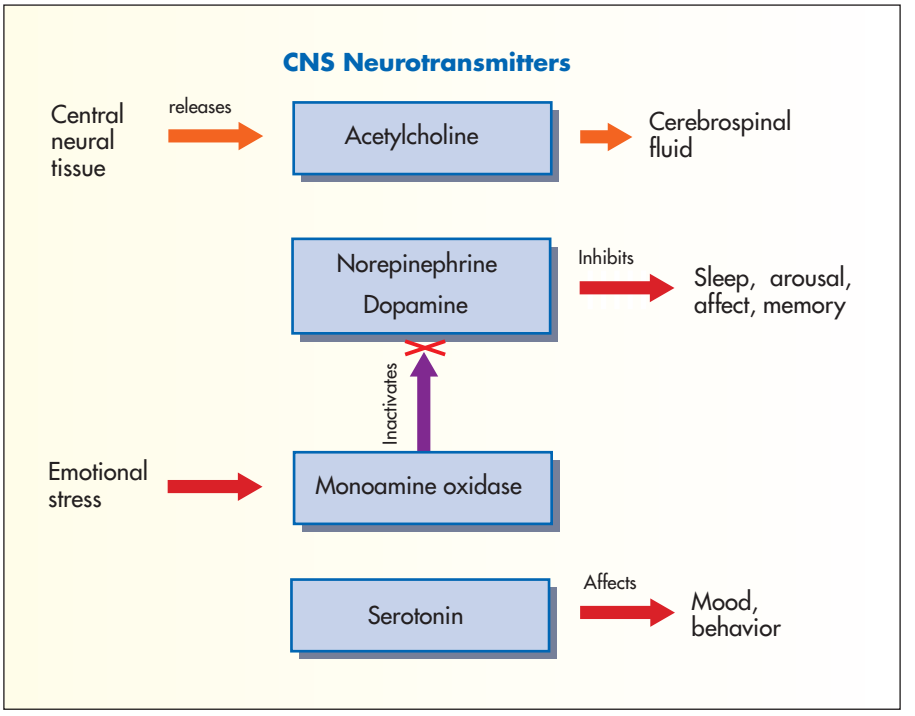

FIGURE 13-10 Neurotransmitters in the brain and their effects on emotion.

ANTIPSYCHOTIC AGENTS

The main use of antipsychotic drugs is to treat *schizophrenia*. This class of drugs is the only clearly effective treatment for this condition. There are other psychiatric indications for the use of antipsychotic drugs. These drugs are used to treat Tourette's syndrome. They also are used to control disturbing behavior in patients with senile dementia associated with Alzheimer's disease. Effective antipsychotic (neuroleptic) drugs block dopamine receptors in specific areas of the CNS. These drugs can be classified into the following groups:

- Phenothiazine derivatives
  Chlorpromazine (Thorazine)
  Thioridazine (Mellaril)
  Fluphenazine (Prolixin)
- Butyrophenone derivatives
  Haloperidol (Haldol)
- Dihydroindolone derivatives
  Molindone (Moban)
- Dibenzoxazepine derivatives
  Loxapine (Loxitane)
- Thienbenzodiazepine derivatives
  Olanzapine (Zyprexa)
- Atypical agents
  Clozapine (Clozaril)
  Risperidone (Risperdal)

With continued use of certain antipsychotics, some patients develop supersensitivity of dopamine receptors. This can lead to tardive dyskinesia or dystonia. **Tardive dyskinesia** is a potentially irreversible neurological disorder characterized by involuntary repetitious movements of the muscles of the face, limbs, and trunk. Other identifying features include excessive blinking of the eyelids, lip smacking, tongue protrusion, foot tapping, and rocking side-to-side. **Dystonia** is characterized by local or diffuse changes in muscle tone. This condition can result in painful muscle spasms, unusually fixed postures, and strange movement patterns.

ANTIDEPRESSANTS

Antidepressants are used to treat affective disorders (mood disturbances) including depression, mania, and elation. Tricyclic antidepressants, selective serotonin reuptake inhibitors, and MAO inhibitors are prescribed for depression; lithium (an antimanic drug) is the preferred treatment for mania (see Chapter 35).

NOTE

Depression may be exogenous or endogenous. *Exogenous depression* results from a person's response to a loss or disappointment (e.g., "the blues"). This type of depression is considered normal. It is usually temporary and remits without the use of drug therapy. *Endogenous depression,* however, lasts 6 months or longer. This type of depression is characterized by the absence of external causes; it may be the result of genetic or biochemical alterations. Antidepressants often are needed to treat this disorder. Depression is discussed further in Chapter 35.

Tricyclic Antidepressants. Tricyclic antidepressants (TCAs) are thought to treat depression by increasing levels (blocking the reuptake) of the neurotransmitters norepinephrine and serotonin. Examples include nortriptyline

(Pamelor) and amitriptyline (Elavil). Excessive doses of these drugs (e.g., TCA overdose) have the potential for cardiac dysrhythmias and cardiovascular collapse (see Chapter 34).

CRITICAL THINKING

You know that tricyclic antidepressants increase the levels of norepinephrine. Thus what side effects might you expect in an overdose?

Selective Serotonin Reuptake Inhibitors. Selective serotonin reuptake inhibitors work to block the reabsorption or reuptake of serotonin. This makes more of the chemical available to the brain. These drugs do have some side effects; for example, insomnia, headache, and diarrhea are common complaints. However, these drugs often treat depression without the adverse effects of other antidepressants, such as the dry mouth caused by tricyclic antidepressants or the dietary restrictions mandated by MAO inhibitors. Examples of selective serotonin reuptake inhibitors are fluoxetine (Prozac), sertraline (Zoloft), paroxetine (Paxil), escitalopram (Lexapro), fluvoxamine (Luvox), and citalopram (Celexa).

Monoamine Oxidase Inhibitor Antidepressants. Central-acting monoamines, especially norepinephrine and serotonin, are thought to cause depression and mania. Monoamine oxidase is an enzyme found in nerve cells. It is thought to be produced during tense emotional states. The enzyme is responsible for metabolizing norepinephrine within the nerve. Monoamine oxidase inhibitors block this enzyme. This leads to increased levels of norepinephrine. Examples of MAO inhibitors used to treat depression include isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate). Monoamine oxidase inhibitors also are used as antihypertensive agents (described later in this chapter).

NOTE

The monoamine oxidase inhibitors used in psychiatric practice are irreversible inhibitors of both forms (A and B) of brain monoamine oxidase. These drugs are rarely used today because of their potentially dangerous interactions with dietary tyramine and other agents that have sympathomimetic or serotoninergic properties.[11]

Lithium. Lithium is a cation that is closely related to sodium. Both cations are transported actively across cell membranes. However, lithium cannot be pumped as effectively out of the cell as sodium. Lithium therefore accumulates in the cells. This results in a decrease in intracellular sodium concentration and perhaps an improvement in the symptoms of a manic state. In addition, lithium appears to enhance some of the actions of serotonin. Lithium may decrease levels of norepinephrine and dopamine. It also appears to block the development of dopamine receptor supersensitivity that may accompany long-term therapy with antipsychotic agents. Lithium carbonate is used to treat manic disorders, such as bipolar disorders. Lithium has a narrow therapeutic range, so toxicity is common.

Drugs for Specific Central Nervous System–Peripheral Dysfunction

Several movement disorders result from an imbalance of dopamine and acetylcholine. Two of the most common are Parkinson's disease (including parkinsonism syndromes) and Huntington's disease.

PARKINSON'S DISEASE

Parkinson's disease is a chronic disabling disease characterized by rigidity of voluntary muscles. Parkinson's disease also is characterized by tremor of the fingers and extremities. The disease most often affects persons over age 60, although it may occur in younger persons. Parkinson's disease may occur especially after acute encephalitis or cases of carbon monoxide or metallic poisoning or from the use of some illicit drugs. The disease is thought to result from an abnormally low concentration of dopamine. *Parkinsonism syndromes* mimic the symptoms of Parkinson's disease. They usually are of an unknown cause (**idiopathic**) but may result from treatment with antipsychotic drugs (*drug-induced parkinsonism*) that block dopaminergic receptors (e.g., ***haloperidol*** [Haldol], metoclopramide [Clopra, Emex], and phenothiazines [e.g., Thorazine, Mellaril]). Symptoms of Parkinson's disease include the following:

- Immobile facial expression (parkinsonism facies)
- Bobbing of the head
- Resting tremor
- Pill-rolling of the fingers
- Shuffling gait
- Forward flexion of the trunk
- Loss of postural reflexes

HUNTINGTON'S DISEASE

Huntington's disease is an inherited disorder characterized by progressive dementia and involuntary muscle twitching (chorea). Like Parkinson's disease, Huntington's disease is thought to be related to an imbalance of dopamine, acetylcholine, and perhaps other neurotransmitters.

Drugs With Central Anticholinergic Activity

Drugs that inhibit or block acetylcholine are referred to as *anticholinergic*. They work by restoring the normal dopamine-acetylcholine balance in the brain. Common anticholinergic agents include benztropine (tablets and injections), ethopropazine hydrochloride, and ***ipratropium*** (Atrovent). Another commonly prescribed anticholinergic is donepezil (Aricept) that is used to treat dementia in patients with mild-to-moderate Alzheimer's disease.

Drugs That Affect Dopamine in the Brain

Three classifications of drugs affect dopamine in the brain: those that release dopamine, those that increase brain levels of dopamine, and dopaminergic agonists (Box 13-21). Levodopa (L-dopa) is a drug that increases brain levels of dopamine. Levodopa is the current drug of choice in the treatment of movement disorders associated with dopamine-acetylcholine imbalance.

MONOAMINE OXIDASE INHIBITORS

Two types of MAO inhibitors have been identified. The first one is *monoamine oxidase A,* which metabolizes norepinephrine and serotonin. The second one is *monoamine oxidase B,* which metabolizes dopamine. Selegiline (Deprenyl) is a selective inhibitor of monoamine oxidase B. It retards the breakdown of dopamine. Selegiline often is used along with levodopa because it enhances and prolongs the antiparkinsonism effects of levodopa. (Selegiline allows the dose of levodopa to be reduced.)

Skeletal Muscle Relaxants

Skeletal muscle contraction is evoked by a nicotinic cholinergic transmission process. Just as the autonomic ganglionic transmission can be modified by drugs, so too can skeletal muscle contractions. Skeletal muscle relaxants can be classified as central-acting, direct-acting, and neuromuscular blockers.

CENTRAL-ACTING MUSCLE RELAXANTS

Central-acting drugs are used to treat muscle spasms. They are thought to work by producing CNS depression in the brain and spinal cord. Antispastic agents include carisoprodol (Soma), cyclobenzaprine (Flexeril), and ***diazepam*** (Valium).

DIRECT-ACTING MUSCLE RELAXANTS

Direct-acting muscle relaxants directly affect skeletal muscles to produce muscle relaxation. This results in a decrease in muscle contraction. Dantrolene (Dantrium) is an example of a direct-acting muscle relaxant.

NEUROMUSCULAR BLOCKERS

Neuromuscular blocking drugs produce complete muscle relaxation and paralysis. They do this by binding to the nicotinic receptor for acetylcholine at the neuromuscular junction. Neuromuscular nerve transmission is thus blocked. Nerve transmission remains blocked for a variable period depending on the type and amount of neuromuscular blocker used.

Neuromuscular blockers sometimes are used to achieve total paralysis before endotracheal intubation (described in Chapter 15), to relieve muscle spasms of the larynx, to suppress tetany, to treat depression resulting from electroconvulsive therapy, and to allow for breathing control by a respirator. These blocking agents can produce complete paralysis. Thus a patient's breathing must be supported. The effectiveness of ventilation and oxygenation must be monitored closely. (These muscle relaxants do not inhibit pain or seizure activity.) Examples of neuromuscular blockers include ***pancuronium*** (Pavulon), ***vecuronium*** (Norcuron), and ***succinylcholine*** (Anectine).

BOX 13-21 Drugs That Affect Dopamine in the Brain

Amantadine (Symmetrel)
Bromocriptine (Parlodel)
Carbidopa-levodopa (Sinemet)
Levodopa (Larodopa)
Pergolide (Permax)

NOTE

The two types of neuromuscular blocking drugs are *depolarizing agents* and *nondepolarizing agents*. Depolarizing agents (e.g., ***succinylcholine***) substitute themselves into the neuromuscular junction. They bind to receptors for acetylcholine (ACh) and have a rapid onset and brief duration of action. This makes them the drug of choice for endotracheal intubation. Nondepolarizing agents bind to the receptors for ACh at the neuromuscular junction. They do this without initiating depolarization of the muscle membrane. Nondepolarizing agents (e.g., ***pancuronium***) have a longer onset and duration than depolarizing agents.

SECTION FOUR
Drugs That Affect the Cardiovascular System

REVIEW OF ANATOMY AND PHYSIOLOGY

The heart consists of many interconnected branching fibers or cells that form the walls of the two atria and two ventricles (see Chapter 10). Some of these cells are specialized to conduct electrical impulses. Others have contraction as their main role. All of these cells are nourished through a profuse network of blood vessels (coronary vasculature). Cardiac drugs are classified by their effects on these tissues. Boxes 13-22 and 13-23 list cardiac drugs and pharmacological terms that describe their actions.

LOOK AGAIN

See Chapter 10: Review of Human Systems, pp. 182-186.

BOX 13-22 Emergency Drugs: Cardiovascular System

Drugs Used to Treat Dysrhythmias

Adenosine (Adenocard)
Amiodarone (Cordarone)
Atropine

Beta-Adrenergic Blockers
Atenolol (Tenormin)
Metoprolol (Lopressor, Toprol-XL)

Calcium Channel Blockers
Diltiazem (Cardizem)
Verapamil (Isoptin)

Dopamine (Intropin)
Isoproterenol (Isuprel)
Lidocaine (Xylocaine)
Magnesium
Procainamide (Pronestyl)

Drugs Used to Optimize Cardiac Output and Blood Pressure

Calcium chloride
Digoxin (Lanoxin)
Dobutamine (Dobutrex)
Dopamine (Intropin)
Epinephrine (Adrenalin)
Nitroglycerin (Nitrostat, Tridil)
Norepinephrine (Levophed)
Vasopressin (Pitressin)

BOX 13-23 Pharmacological Terms to Describe Actions of Cardiovascular Drugs

Chronotropic: Chronotropic drugs affect heart rate. If the drug accelerates the heart rate (e.g., isoproterenol [Isuprel]), it is said to have a positive chronotropic effect. A drug that decreases the heart rate (e.g., verapamil [Isoptin]) is said to have a negative chronotropic effect.

Dromotropic: Dromotropic drugs affect conduction velocity through the conducting tissues of the heart. If a drug accelerates conduction, it is said to have a positive dromotropic effect. Examples of drugs with positive dromotropic effects include isoproterenol (Isuprel) and phenytoin (Dilantin). Drugs with negative dromotropic effects delay conduction (e.g., verapamil [Isoptin] and adenosine [Adenocard]).

Inotropic: Inotropic drugs strengthen or increase the force of cardiac contraction (a positive inotropic effect). Some examples include digoxin (Lanoxin), dobutamine (Dobutrex), epinephrine (Adrenalin), and isoproterenol (Isuprel). A drug that weakens or decreases the force of cardiac contraction has a negative inotropic effect. An example of such a drug is propranolol (Inderal).

Cardiac Glycosides

Cardiac glycosides are naturally occurring plant substances. They have characteristic effects on the heart. These compounds contain a carbohydrate molecule (sugar). When combined with water, the molecule is converted into a sugar plus one or more active substances. Glycosides may work by blocking certain ionic pumps in the cellular membrane. This indirectly increases the calcium concentration to the contractile proteins. A key cardiac glycoside is ***digoxin*** (Lanoxin). ***Digoxin*** is used to treat heart failure and to manage certain tachycardias (see Chapter 22).

Digitalis glycosides affect the heart in two distinct ways. First, they increase the strength of contraction. This is a **positive inotropic effect.** Second, they have a dual effect on the electrophysiological properties of the heart. They have a modest negative chronotropic effect. (This causes slight slowing of the heart rate.) They also have a profound negative dromotropic effect, decreasing conduction velocity of impulses in the heart.

Many patients who take cardiac glycosides develop side effects at one time or another because of the narrow therapeutic index of the drugs. The symptoms may be neurological, visual, gastrointestinal, cardiac, or psychiatric. These symptoms often are vague and the patient can easily attribute them to a viral illness. A high index of suspicion in patients taking cardiac glycosides who report experiencing flulike symptoms is important. The most common side effects of cardiac glycosides are anorexia, nausea or vomiting, visual disturbances (flashing lights, altered color vision), and **dysrhythmias** (cardiac rhythm disturbances), usually slowing of the heart rate with varying degrees of blocked conduction (see Chapter 22).

NOTE

Proarrhythmias are serious dysrhythmias that are generated by antidysrhythmic agents. All antidysrhythmic drugs have some degree of proarrhythmic effects. The sequential use of two or more antidysrhythmic drugs compounds these effects. As a rule, it is best not to use more than one agent to manage dysrhythmias (unless absolutely necessary).

The toxic effects of cardiac glycosides are dose related. These effects may be increased by the presence of other drugs, such as diuretics. These other drugs may predispose the patient to cardiac rhythm disturbances. Dysrhythmias may include bradycardias, tachycardias, and even ventricular fibrillation. For these reasons, patients taking these drugs require close monitoring. Treatment for digitalis toxicity may include correction of electrolyte imbalances, neutralization of the free drug, and use of antidysrhythmics. A patient with a low potassium level is much more likely to develop digoxin toxicity.

Antidysrhythmics

Antidysrhythmic drugs are used to treat and prevent disorders of cardiac rhythm. The pharmacological agents that suppress dysrhythmias may do so by direct action on the cardiac cell membrane (***vasopressin*** [Pitressin]), by indirect action that affects the cells (***propranolol*** [Inderal]), or both.

Cardiac rhythm disturbances may be caused by a number of factors. These include ischemia, hypoxia, acidosis or alkalosis, electrolyte abnormalities, excessive catecholamine exposure, autonomic influences, drug toxicity, or scarred and diseased tissue. Dysrhythmias result from disturbances in impulse formation, disturbances in impulse conduction, or both.

CLASSIFICATIONS

Antidysrhythmic drugs have been classified into categories based on their fundamental mode of action on cardiac muscle. Drugs that belong to the same class do not always produce identical actions. However, all antidysrhythmic drugs have some ability to suppress *automaticity*.

NOTE

Local protocols and standing orders assist and guide EMS personnel. These orders often are established to allow paramedics to use certain drugs in certain cases. With these orders in place, paramedics can act without seeking medical direction. One such example is antidysrhythmic drugs for a patient with specific cardiac conduction disturbances. Another is first-line cardiac life support drugs for a patient in cardiac arrest.

Class I. Class I drugs are sodium channel blockers. These work to slow conduction. They are divided further into subclasses (Ia, Ib, and Ic) based on the extent of sodium channel blockade. Examples of Class Ia drugs include quinidine (Quinaglute, Duraquin), disopyramide (Norpace), and ***procainamide*** (Pronestyl). Class Ib drugs decrease or have no effect on conduction velocity. Examples include ***lidocaine*** (Xylocaine) and ***phenytoin*** (Dilantin). Class Ic drugs profoundly slow conduction and are indicated only for control of life-threatening ventricular dysrhythmias. An example of a Class Ic drug is flecainide (Tambocor).

CRITICAL THINKING

How might the signs of shock in a patient taking digoxin (Lanoxin) or propranolol (Inderal) vary from what might be expected normally?

Class II. Class II drugs are beta-blocking agents. These drugs reduce adrenergic stimulation of the heart. An example is ***metoprolol*** (Lopressor).

Class III. Class III drugs produce potassium channel blockade. This increases the contractility. Unlike other antidysrhythmic agents, drugs in this class do not suppress automaticity. They also have no effect on conduction velocity. These drugs are thought to cease dysrhythmias that result from the reentry of blocked impulses. An example of such a drug is ***amiodarone*** (Cordarone).

Class IV. Class IV drugs are also known as *calcium channel blockers*. These drugs are thought to work by blocking the inflow of calcium through the cell membranes of the cardiac and smooth muscle cells. This action depresses the myocardial and smooth muscle contraction, decreases automaticity, and in some cases decreases conduction velocity. Examples of calcium channel blockers include ***verapamil*** (Isoptin) and ***diltiazem*** (Cardizem).

Antihypertensives

High blood pressure affects as many as 50 million adults and children in the United States[9] and has been related directly to an increased incidence of stroke, cerebral hemorrhage, heart and renal failure, and coronary heart disease. The exact mechanism of action of many antihypertensive drugs is unknown. The ideal antihypertensive drug should accomplish the following:

- Maintain blood pressure within normal limits for various body positions
- Maintain or improve blood flow without compromising tissue perfusion or blood supply to the brain
- Reduce the workload of the heart
- Have no undesirable side effects
- Permit long-term administration without intolerance

CLASSIFICATIONS

Certain drugs are used to reduce blood pressure in patients with chronic hypertension. These drugs usually are given in low-dose combinations and are *titrated* (gradually adjusted) to effect. These drugs include diuretics, sympathetic blocking agents (sympatholytic drugs), vasodilators, angiotensin-converting enzyme (ACE) inhibitors, calcium channel blockers, and the newer class, angiotensin II receptor antagonists.

Diuretics. Diuretics are the drugs of choice in managing hypertension. They often are used with other antihypertensive agents. Diuretics cause a loss of excess salt and water from the body by the kidneys. The decrease in plasma and extracellular fluid volume decreases preload and stroke volume. The decrease in fluid volume has a direct effect on the size of the arterioles, resulting in lowered blood pressure. This response causes an initial decline of cardiac output. That is followed by a decrease in peripheral vascular resistance. These responses result in a lowering of the blood pressure.

Thiazides are diuretics that work well to lower blood pressure. Many antihypertensive agents cause retention of sodium and water. Yet thiazides may be given concomitantly (along with other drugs) to help prevent this side effect. An example of a thiazide diuretic is hydrochlorothiazide (HCTZ).

Loop diuretics are strong, short-acting agents. They inhibit sodium and chloride reabsorption in the loop of

Henle. These drugs cause excessive loss of potassium. They also cause an increase in the excretion of sodium and water. Loop diuretics have fewer side effects than most other antihypertensives. However, hypokalemia and profound dehydration can be a result of their use. These agents are prescribed to patients who have renal insufficiency. They also may be given to patients who cannot take other diuretics. An example of a loop diuretic is ***furosemide*** (Lasix).

NOTE

Many drugs are excreted by the kidneys. Thus patients with renal system dysfunction (acute or chronic renal failure) may accumulate drugs in their systems. These patients often require modifications in drug doses and dosing intervals. These changes are in addition to diet modification and fluid restriction.

Potassium-sparing agents can be effective as an antihypertensive when they are used in combination with other diuretics. They promote sodium and water loss without a loss of potassium. These agents are used to treat hypertensive patients who become hypokalemic from other diuretics. They also can be used by patients who are apparently resistant to the antihypertensive effects of other diuretics. Potassium-sparing agents are also used to treat some edematous states. (An example of such is cirrhosis of the liver with ascites.) An example of a potassium-sparing agent is spironolactone (Aldactone).

Sympathetic Blocking Agents. Sympathetic blocking agents may be classified as *beta-blocking agents* and *adrenergic-inhibiting agents*. Beta-blocking agents are used to treat cardiovascular disorders, including patients with suspected myocardial infarction, high-risk unstable angina, and hypertension. These drugs work by decreasing cardiac output and inhibiting renin secretion from the kidneys. Both actions result in lower blood pressure. Beta-blocking drugs compete with epinephrine for available beta-receptor sites as well. This inhibits tissue and organ response to beta stimulation. Examples of beta-blocking agents include the following:

- $Beta_1$-blocking agents (cardioselective)
  Acebutolol (Sectral)
  Atenolol (Tenormin)
  Metoprolol (Lopressor, Toprol-XL)
- $Beta_1$- and $beta_2$-blocking agents (nonselective)
  Labetalol (Normodyne, Trandate) (also has $alpha_1$-blocking properties)
  Nadolol (Corgard)
  Propranolol (Inderal)

Adrenergic-inhibiting agents work by modifying the actions of the sympathetic nervous system. They are effective antihypertensive drugs. Arterial pressure is influenced through various mechanisms of the heart, blood vessels, and kidneys. Sympathetic stimulation increases the heart rate and force of myocardial contraction, constricts arterioles and venules, and causes the release of renin from the kidneys. Blocking this sympathetic stimulation can reduce blood pressure.

Adrenergic-inhibiting agents are classified as *centrally acting adrenergic inhibitors* or *peripheral adrenergic inhibitors*. The mechanism by which many of these agents work is unknown. Generally, most of these agents are believed to have multiple sites of action. Examples include the following drugs:

- Centrally acting adrenergic inhibitors
  Clonidine hydrochloride (Catapres)
  Methyldopa (Aldomet)
  Prazosin hydrochloride (Minipress)
- Peripheral adrenergic inhibitors
  Doxazosin (Cardura)
  Guanethidine sulfate (Ismelin)
  Reserpine (Sandril, Serpasil)
  Phentolamine (Regitine)
  Phenoxybenzamine (Dibenzyline)
  Terazosin (Hytrin)

Vasodilator Drugs. Vasodilator drugs act directly on the smooth muscle walls of the arterioles, veins, or both. They lower peripheral resistance. Thus they lower blood pressure. This stimulates the sympathetic nervous system and also activates the baroreceptor reflexes. In turn this leads to an increase in heart rate, cardiac output, and renin release. Medications that inhibit the sympathetic response usually are given with vasodilator drugs.

In addition to their use as antihypertensives, some vasodilator drugs work to treat angina pectoris (ischemic chest pain). For example, nitrates dilate veins and arteries. Their dilating effects on veins lead to venous pooling of blood. They also reduce the amount of blood return to the heart. Thus these effects reduce *left ventricular end-diastolic pressure and volume* (the volume of blood in the left ventricle at the end of filling) (see Chapter 22). The subsequent decrease in wall tension helps to reduce myocardial oxygen demand and also relieves the chest pain of myocardial ischemia. Vasodilator drugs are classified as *arteriolar dilators* and *arteriolar and venous dilators*. Examples of each include the following:

- Arteriolar dilator drugs
  Hydralazine (Apresoline)
  Minoxidil (Loniten)
- Arteriolar and venous dilator drugs
  Sodium nitroprusside (Nipride, Nitropress)
  Nitrates and nitrites
  Amyl nitrite inhalant
  Isosorbide dinitrate (Isordil, Sorbitrate)
  Nitroglycerin sublingual tablet (Nitrostat)
  Nitropaste (Nitro-Bid ointment, Nitrostat, Nitrol)
  Intravenous ***nitroglycerin*** (Tridil)

Angiotensin-Converting Enzyme (ACE) Inhibitor Drugs. As described in Chapter 11, the renin-angiotensin-aldosterone system plays a key role in maintaining blood pressure. This system also plays a key role in sodium and fluid balance. A disturbance in this system can result in hypertension, edema, and congestive heart failure.

In addition, kidney damage can result in an inability to regulate the release of renin through normal feedback mechanisms. This causes elevated blood pressure in some patients.

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 239-240.

Angiotensin II is a strong vasoconstrictor that raises blood pressure and also causes the release of aldosterone. Aldosterone contributes to sodium and water retention. By inhibiting conversion of the precursor angiotensin I to the active molecule angiotensin II (a process triggered by ACE), the renin-angiotensin-aldosterone system is suppressed and blood pressure is lowered. Examples of ACE inhibitors include ***captopril*** (Capoten), ***enalapril*** (Vasotec), benazepril (Lotensin), fosinopril (Monopril), ***lisinopril*** (Prinivil, Zestril), and quinapril (Accupril).

Calcium Channel Blockers. Calcium channel blocking agents such as ***verapamil*** (Isoptin), amlodipine (Norvasc), felodipine (Plendil), and ***diltiazem*** (Cardizem, Tiazac) reduce peripheral vascular resistance by inhibiting the contractility of vascular smooth muscle. They dilate coronary vessels through the same mechanism. The effects of these drugs are important in treating hypertension, decreasing the oxygen requirements of the heart (through decreased afterload), and increasing oxygen supply (by abolishing coronary artery spasm), thus relieving the causes of angina pectoris. The various drugs in this class differ in degree of selectivity for coronary (and peripheral) vasodilation or decreased cardiac contractility.

Angiotensin II Receptor Antagonists

Angiotensin II receptor antagonists are a newer class of antihypertensive agent. They block the renin-angiotensin-aldosterone system more completely than ACE inhibitors. They lower blood pressure by selectively inhibiting the actions of angiotensin II receptors, which include vasoconstriction, renal tubular sodium reabsorption, aldosterone release, and stimulation of central and peripheral sympathetic activity. These drugs are used to manage hypertension in those who cannot cope with the adverse effects of ACE inhibitors (e.g., dry cough). The drugs appear to be equally effective in lowering systolic and diastolic pressure. They also are being studied for their effectiveness in treating congestive heart failure, diabetic nephropathy, and vascular diseases such as atherosclerosis. Drugs in this classification include candesartan (Atacand), irbesartan (Avapro), losartan (Cozaar, Hyzaar), telmisartan (Micardis), and valsartan (Diovan) (Figure 13-11).

Antihemorrheologic Agents

Antihemorrheologic agents are used to treat peripheral vascular disorders caused by pathological or physiological obstruction (e.g., arteriosclerosis). These drugs improve blood flow and the delivery of oxygen to ischemic tissues. They do this by restoring red blood cell flexibility to traverse narrow vessels, and by lowering blood viscosity. An example of an antihemorrheologic agent is pentoxifylline (Trental).

SECTION FIVE
Drugs That Affect the Blood

ANTICOAGULANTS, FIBRINOLYTICS, AND BLOOD COMPONENTS

Bleeding and thrombosis are altered states of hemostasis. An understanding of the drugs that affect blood coagulation and the use of fibrinolytic agents and blood components is crucial. In the prehospital arena, these concepts will assist in the management of patients.

Anticoagulants

As described in Chapter 10, platelets are small cell fragments in the blood. They provide the initial step in normal repair of blood vessels. **Blood coagulation** is a process that results in the formation of a stable fibrin clot that entraps platelets, blood cells, and plasma. The end result of this process is called a blood clot or thrombus. Abnormal thrombus formation is the major cause of myocardial infarction (from coronary thrombosis) and stroke (from cerebral vascular thrombosis) (see Chapter 22).

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 178-182.

Thrombus formation can occur in both the venous and arterial systems. An example of thrombosis in the venous system is pulmonary embolus and deep vein thrombosis. The three major risk factors for various thromboses are *stasis, localized trauma,* and *hypercoagulable states*. Stasis (reduced blood flow) results from immobilization or venous insufficiency. Stasis is responsible for the increased incidence of *deep vein thrombosis* (DVT) in many bedridden patients. Localized trauma may initiate the clotting cascade and may cause arterial and venous thrombosis. *Hypercoagulability* is the increased likelihood of blood to become abnormally thick and thus increase the formation of fibrin complexes in the blood vessels. It is the cause of the increased incidence of deep vein thrombosis in women who take birth control pills. Hypercoagulability is also a factor in clotting problems for many of the familial thrombotic disorders (see Chapter 22).

Arterial thrombi commonly are associated with atherosclerotic plaques, hypertension, and turbulent blood flow that damages the endothelial lining of blood vessels. Damage to the endothelium causes platelets to stick and *aggregate* (clump) in the arterial system. Arterial thrombi are

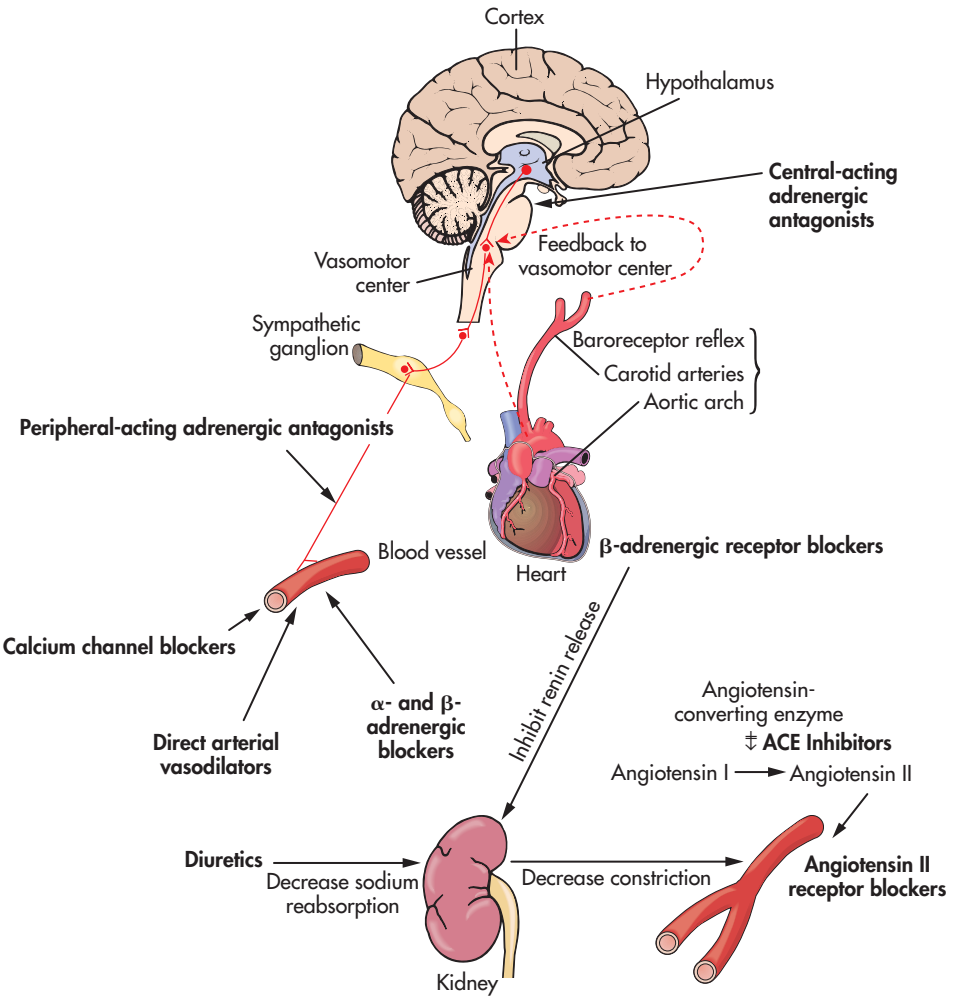

FIGURE 13-11 Sites of action of antihypertensive agents.

composed mostly of platelets, but they also involve the chemical substances that contribute to the coagulation process (in particular, fibrinogen and fibrin). Myocardial infarctions and strokes are often the result of arterial thrombi.

AGENTS THAT AFFECT BLOOD COAGULATION

Drugs that affect blood coagulation may be classified as *antiplatelet, anticoagulant,* and *fibrinolytic agents*. They each act at a different phase in the clotting process.

Antiplatelet Agents. Drugs that interfere with platelet aggregation are known as *antiplatelet* drugs. These drugs sometimes are prescribed prophylactically (as a precaution) for patients at risk of developing arterial clots. They also are prescribed for those who have suffered myocardial infarction or stroke. Antiplatelet agents also are given to patients with certain valvular heart diseases, valvular prostheses (replacement valves), and various intracardiac shunts (a passage that allows blood to flow from one part of the heart to another). Among the most common oral antiplatelet drugs are ***aspirin,*** dipyridamole (Persantine), clopidogrel (Plavix), and ticlopidine (Ticlid).

NOTE

Platelet adhesion, activation, and aggregation that result in the formation of an arterial thrombus are pivotal in the pathogenesis of acute coronary syndromes (acute myocardial infarctions). Studies indicate that the administration of a glycoprotein IIb/IIIa receptor antagonist may reduce ischemic complications after plaque fissure or rupture. (These drugs inhibit glycoprotein receptors in the membrane of platelets and help prevent platelet aggregation.) These drugs may be included along with aspirin, heparin, and beta blockers during in-hospital reperfusion therapy for select patients. Examples of glycoprotein IIb/IIIa inhibitors include ***abciximab*** (ReoPro), ***eptifibatide*** (Integrilin), and ***tirofiban*** (Aggrastat).

Anticoagulant Agents. Anticoagulant drug therapy is used to prevent intravascular thrombosis. The therapy works by decreasing blood coagulability. Such therapy commonly is used to prevent postoperative thromboembolism. Anticoagulant agents also are used during hemodialysis and in reperfusion therapy for some patients with acute coronary syndromes (see Chapter 22). Anticoagulant therapy is a preventive measure against future clot formation. The therapy has no direct effect on a blood clot that has formed already or on ischemic tissue injured by inadequate blood supply as a result of a thrombus. The major side effect of anticoagulant therapy is hemorrhage and bleeding complications. Examples of anticoagulant agents include warfarin (Coumadin) and ***heparin.***

NOTE

Natural (unfractionated) heparin and its derivative, low-molecular-weight heparin (LMWH), are effective and indicated for the prevention of venous thromboembolism. Heparin also is indicated for the treatment of venous thrombosis, pulmonary embolism, and acute myocardial infarction. In addition, heparin is administered to patients who undergo cardiac surgery using cardiac bypass, vascular surgery, and coronary angioplasty; in patients with coronary stents; and in selected patients with coagulation disorders.[12]

Natural heparin is usually administered in the hospital. It is given intravenously (IV) and requires laboratory monitoring. LMWH (e.g., enoxaparin [Lovenox, Clexane]) may be given IV or subcutaneously in weight-adjusted doses. LMWH does not require laboratory monitoring and therefore may be given in the out-of-hospital or home setting. LMWH is given in the prehospital setting to some patients with ischemic chest pain and myocardial infarction (see Chapter 22).

Fibrinolytic Agents. Fibrinolytic drugs dissolve clots after their formation. They do so by promoting the digestion of fibrin. Fibrinolytic therapy has become the treatment of choice for treating acute myocardial infarction in certain groups of patients. Fibrinolytic therapy also has become the treatment of choice in managing some stroke patients. The goal is to reestablish blood flow and prevent ischemia and tissue death. Fibrinolytic therapy also has been used in acute pulmonary embolism, deep vein thrombosis, and peripheral arterial occlusion. Fibrinolytics are used in the prehospital setting in some areas of the United States. These drugs include anistreplase (APSAC, Eminase), ***alteplase*** (t-PA), ***reteplase*** (Retavase), ***streptokinase*** (Streptase), and tenecteplase (TNKase) (see Chapter 22 and Emergency Drug Index).

CRITICAL THINKING

Fibrinolytics have the potential to dissolve clots. This in turn may reverse the serious effects of myocardial infarction and stroke. So why are fibrinolytics not given to everyone who is suspected of having these conditions?

Antihemophilic Agents

Hemophilia (further described in Chapter 32) is a group of hereditary bleeding disorders in which the affected individual lacks one of the factors needed for the coagulation of blood. These disorders are characterized by persistent and uncontrollable bleeding that can occur after even a minor injury. Bleeding may occur into joints, the urinary tract, and at times the CNS. *Hemophilia A* is the classic form of hemophilia and is caused by a deficiency of factor VIII. *Hemophilia B* results from a deficiency in factor IX complex. Replacement therapy of the missing clotting factor can be effective in managing hemophilia. These include factor VIII (Factorate), factor IX (Konyne), and antiinhibitor coagulant complex (Autoplex).

NOTE

Coagulation factors refer to the 13 proteins contained in blood plasma. These proteins interact to produce a blood clot.

Hemostatic Agents

Hemostatic agents hasten clot formation. The formation of clots in turn reduces bleeding. Systemic hemostatic agents (e.g., Amicar and Cyklokapron) generally are used to control rapid blood loss after surgery by inhibiting fibrinolysis. Topical hemostatic agents (e.g., Gelfoam and Novacell) are used to control capillary bleeding during surgical and dental procedures.

Hemostatic agents are now being used in the prehospital setting and in combat medical care. Celox, WoundStat, and QuickClot work by absorbing plasma from blood, thereby reducing clotting times. Chitosan, a substance derived from shrimp shells, is another hemostatic agent that adheres to and seals wounds[13] (see Chapter 38).

Blood and Blood Components

The healthy body maintains a normal balance of blood and its components. However, illness and injury such as hemorrhage, burns, and dehydration may affect this balance. These conditions may impair this balance and require replacement therapy (see Appendix: Advanced Care Procedures for Critical Care Paramedics).

Knowledge of how to manage an imbalance of blood or blood components is crucial. The usual treatment of choice is to replace the sole blood component that is deficient. Replacement therapy may include transfusing the following:

- Whole blood (red blood cells and plasma; rarely used)
- Packed red blood cells (red blood cells without plasma)
- Fresh-frozen plasma (plasma without red blood cells or platelets)
- Plasma expanders (dextran)
- Platelets
- Cryoprecipitate (multiple clotting factors)

BOX 13-24 Examples of Antihyperlipidemic Drugs

Atorvastatin (Lipitor)
Fenofibrate (Tricor)
Fluvastatin (Lescol)
Gemfibrozil (Lopid)
Pravastatin (Pravachol)
Simvastatin (Zocor)
Nicotinic acid (Niacin)
Rosuvastatin (Crestor)

- Fibrinogen (found in fresh frozen plasma [FFP] and cryoprecipitate)
- Albumin
- Gamma globulins (antibodies)

Antihyperlipidemic Drugs

Hyperlipidemia refers to an excess of lipids in the plasma. Several types of hyperlipidemia occur; all are associated with elevated levels of cholesterol and triglycerides (described in Chapter 2). This condition is thought to play a role in the development of atherosclerosis. Thus antihyperlipidemic drugs sometimes are used along with diet and exercise to control serum lipid levels (Box 13-24).

LOOK AGAIN
See Chapter 2: Well Being of the Paramedic, pp. 25-28.

SECTION SIX
Drugs That Affect the Respiratory System

REVIEW OF ANATOMY AND PHYSIOLOGY

The respiratory system includes all structures that are involved in the exchange of oxygen and carbon dioxide. Serious narrowing of any portion of the respiratory tract may be an indication for drug therapy (Box 13-25). Emergencies involving the respiratory system usually are caused by reversible conditions such as asthma, emphysema with infection, and foreign body airway obstruction (see Chapter 15).

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 191-196.

BOX 13-25 Emergency Drugs: Respiratory System

Albuterol (Proventil, Ventolin)
Levalbuterol (Xopenex)
Epinephrine (Adrenalin) 1:1000
Racemic epinephrine (microNephrin)

Smooth muscle fibers line the tracheobronchial tree. They directly influence the diameter of the airways. The bronchial smooth muscle tone is maintained by impulses from the autonomic nervous system. Parasympathetic fibers from the vagus nerve stimulate bronchial smooth muscle through the release of acetylcholine. This neurotransmitter interacts with the muscarinic receptors on the membranes of the cell, producing bronchoconstriction.

Sympathetic fibers mainly affect $beta_2$ receptors in the lungs through the release of epinephrine from the adrenal medulla and the release of norepinephrine from the peripheral sympathetic nerves. The epinephrine reaches the lungs via the circulatory system. Epinephrine interacts with $beta_2$ receptors to produce smooth muscle relaxation and bronchodilation. Thus the $beta_2$ receptor plays the dominant role in bronchial muscle tone. (Although $beta_1$ receptors also are found on bronchial smooth muscle, their ratio to $beta_2$ receptors is 1:3.)

Bronchodilators

Bronchodilator drugs are the primary treatment for obstructive pulmonary disease such as asthma, chronic bronchitis, and emphysema. These drugs are classified as sympathomimetic drugs or xanthine derivatives. Many of these drugs are administered by inhalation via a nebulizer or pressure cartridge (see Chapter 24).

SYMPATHOMIMETIC DRUGS

Sympathomimetic drugs are grouped according to their effects on receptors. Nonselective adrenergic drugs have alpha, $beta_1$ (cardiac), and $beta_2$ (respiratory) activity. Nonselective beta-adrenergic drugs have $beta_1$ and $beta_2$ effects. Selective $beta_2$-receptor drugs act primarily on $beta_2$ receptors in the lungs (bronchial smooth muscle). Box 13-26 summarizes the alpha, $beta_1$, and $beta_2$ activities of the adrenergic drugs used as bronchodilators.

Nonselective adrenergic drugs stimulate alpha and beta receptors. The alpha activity lessens vasoconstriction to reduce mucosal edema. $Beta_2$ activity produces bronchodilation and vasodilation. Undesirable $beta_1$ effects include an increase in heart rate and force of contraction. Undesirable $beta_2$ effects include muscle tremors and CNS stimulation. Examples of nonselective adrenergic drugs include nonprescription epinephrine inhalation aerosol (Bronkaid Mist, Primatene Mist) and epinephrine inhalation solution

BOX 13-26 Alpha, Beta$_1$, and Beta$_2$ Activities of Adrenergic Drugs Used as Bronchodilators

Alpha Effects (Vasoconstriction)
Vasoconstriction
Increased blood pressure
Decreased bronchial congestion
Increased duration of action for coadministered beta$_2$ drugs

Beta$_1$ Effects
Cardiac stimulation
Increased heart rate
Increased force of contraction
Possible palpitations and dysrhythmias
Relaxation of gastrointestinal tract
Some bronchodilation and increased heart rate
Fewer effects than with subcutaneous administration

Beta$_2$ Effects
Bronchiole dilation
Stimulation of skeletal muscles (tremors)
Vasodilation (mainly in blood vessels supplying muscle)
Glycogenolysis

Central Nervous System Effects
Anxiety
Dizziness
Insomnia
Irritability
Nervousness
Sweating
Lower incidence of systemic effects than with subcutaneous administration

(Adrenalin). ***Racemic epinephrine*** inhalation solution (microNephrin) is another nonselective adrenergic drug. It is used mainly to manage upper airway swelling associated with *croup* (see Chapter 24).

Nonselective beta-adrenergic drugs are not selective for beta$_2$ receptors. Thus they have a wide range of effects (described earlier in this chapter). This class of drug is no longer recommended for the management of asthma.[14] Examples of nonselective beta-adrenergic drugs include ***epinephrine*** (Adrenalin, Asmolin, and others), ephedrine (Ephed II), and ethylnorepinephrine (Bronkephrine), each of which has some alpha activity; isoproterenol inhalation solution (Aerolone, Vapo-Iso, Isuprel); and isoproterenol inhalation aerosol (Isuprel Mistometer, Norisodrine Aerotrol).

The action of beta$_2$-selective drugs lessens the incidence of unwanted cardiac effects caused by beta$_1$-adrenergic agents. Patients with hypertension, cardiac disease, or diabetes can better tolerate this group of bronchodilators. Examples of selective beta$_2$-receptor drugs include ***albuterol*** (Proventil, Ventolin), ***levalbuterol*** (Xopenex), pirbuterol (Maxair), bitolterol (Tornalate), salmeterol (Serevent), formoterol (Foradil aerolizer), and isoetharine (Bronkosol, others).

NOTE
Some bronchodilators act rapidly ("rescue inhalers") whereas others provide slow relief. If a patient claims to have used his or her inhaler, it is important to ask the patient which inhaler was used.

XANTHINE DERIVATIVES

The xanthine group of drugs includes caffeine, theophylline, and theobromine. These drugs relax smooth muscle (particularly bronchial smooth muscle), stimulate cardiac muscle and the CNS, increase diaphragmatic contractility, and promote diuresis through increased renal perfusion. The action of various theophylline compounds depends on the concentration of theophylline, which is the active ingredient. Theophylline products vary in their rate of absorption and therapeutic effects. Aminophylline (Amoline, Somophyllin, Theo-Dur, Aminophyllin), dyphylline (Dilor, Droxine, Lufyllin), and theophylline (Bronkodyl, Elixophyllin, Somophyllin-T, others) are some of the many theophylline-containing preparations. Theophylline preparations generally are not considered a first-line drug in the treatment of acute reactive airway disease such as asthma. This is because of their high side effect profile and slow onset of action.

Other Respiratory Drugs

A number of other drugs can be used to treat asthma and other obstructive pulmonary diseases. These drugs include prophylactic asthmatic agents such as cromolyn sodium (Intal, sodium cromoglycate); aerosol corticosteroid agents such as beclomethasone dipropionate (Vanceril inhaler, Beclovent); ***dexamethasone*** (Decadron); antileukotrienes such as montelukast (Singulair) and zafirlukast (Accolate); and muscarinic antagonists (anticholinergics) such as ***ipratropium*** (Atrovent) and glycopyrrolate (Robinul). These drugs reduce the allergic or inflammatory response to a variety of stimuli. They also have an effect on bronchial smooth muscle. In the acute care setting, intravenously administered steroids (e.g., ***methylprednisolone*** [Solu-MedRol]) may be given in an attempt to decrease the inflammatory response and improve airflow.

Mucokinetic Drugs

Mucokinetic drugs are used to move respiratory secretions along the tracheobronchial tree. These agents work by altering the consistency of these secretions. Thus the secretions can be removed from the body more easily. Persons with chronic pulmonary disease often use mucokinetic drugs. These drugs help to clear their respiratory passages. They also improve ciliary activity in the airways. Mucokinetic drugs include diluents (water, saline solution), aerosols, and mucolytic drugs or expectorants (Mucomyst).

NOTE

Mucus is a normal secretion produced by the surface cells in the mucous membranes. *Sputum* is an abnormal viscous secretion. Sputum consists mainly of mucus. Sputum originates in the lower respiratory tract.

Oxygen and Miscellaneous Respiratory Agents

Oxygen is mainly used to treat hypoxia and hypoxemia. Oxygen is a colorless, odorless, and tasteless gas. It is essential for sustaining life. (Oxygen and oxygen delivery are described in detail in Chapter 15.)

DIRECT RESPIRATORY STIMULANTS

Direct respiratory stimulants are known as *analeptics*. These act directly on the medullary center of the brain to increase the rate and depth of respirations. These drugs are considered inferior to mechanical ventilatory measures to treat respiratory depression and to counteract drug-induced respiratory depression caused by anesthetics. An example of a direct respiratory stimulant is doxapram (Dopram).

REFLEX RESPIRATORY STIMULANTS

Spirits of ammonia is given by inhalation and acts as a reflex respiratory stimulant. The noxious vapor is used sometimes in cases of fainting. The vapor works by irritating sensory nerve receptors in the throat and stomach. These nerve receptors send afferent messages to the control centers of the brain to stimulate respiration.

RESPIRATORY DEPRESSANTS

Respiratory depressants include opiates and barbiturate drugs previously described. Respiratory depression is a common side effect of these drugs. However, they seldom are given to intentionally inhibit rate and depth of respiration.

COUGH SUPPRESSANTS

The cough is a protective reflex to expel harmful irritants. It may be *productive* when removing irritants or secretions from the airway, or *nonproductive* (dry and irritating). When the cough is prolonged or secondary to an underlying disorder, treatment with antitussive drugs may be indicated. Box 13-27 presents a few narcotic and nonnarcotic antitussive agents.

BOX 13-27 Examples of Narcotic and Nonnarcotic Antitussive Agents

Narcotic Agent
Codeine

Nonnarcotic Agents
Benzonatate (Tessalon)
Dextromethorphan (Sucrets, Robitussin DM)

ANTIHISTAMINES

Histamine is a chemical mediator found in almost all body tissues. The concentration is highest in the skin, lungs, and gastrointestinal tract. The body releases histamine when exposed to an antigen, such as pollen or insect stings. This results in increased localized blood flow, increased capillary permeability, and swelling of the tissues. In addition, histamine produces contractile action on bronchial smooth muscle.

Allergic responses involving histamines and other chemical mediators include local effects such as angioedema, eczema, rhinitis (runny nose), urticaria (hives), and asthma. Systemic effects from the release of histamine and certain other mediators may result in anaphylaxis (see Chapter 27).

Antihistamines compete with histamine for receptor sites. Thus they prevent the physiological action of histamine. Two types of histamine receptors are H_1 *receptors* (these act mainly on the blood vessels and the bronchioles) and H_2 *receptors* (these act mainly on the gastrointestinal tract). In addition to blocking some actions of histamine, antihistamines also have anticholinergic or atropine-like action. This may result in tachycardia, constipation, drowsiness, sedation, and inhibition of secretions. Most antihistamines have a local anesthetic effect as well. This effect may soothe the skin irritation caused by an allergic reaction. The chief clinical use of antihistamines is for allergic reactions. However, they also sometimes are prescribed to control motion sickness or as a sedative or antiemetic. Examples of antihistamines are dimenhydrinate (Dramamine), ***diphenhydramine*** (Benadryl), ***hydroxyzine*** (Vistaril), ***promethazine*** (Phenergan, others), and the newer H_1-receptor antagonists, for example, loratadine (Claritin), cetirizine (Zyrtec), and fexofenadine (Allegra).

SEROTONIN

Serotonin is a naturally occurring vasoconstrictor material found in platelets and in the cells of the brain and intestine. It has several pharmacological actions, which are exerted on various smooth muscles and nerves. Serotonin is not administered as a drug, but has a major influence on other drugs and some disease states. It is helpful in repairing damaged blood vessels, stimulates smooth muscle contraction, and acts as a neurotransmitter in the CNS, where it has an effect on sleep, pain perception, and some mental illnesses.

ANTISEROTONINS

Antiserotonins are serotonin antagonists. They work to inhibit responses to serotonin and its influence on other drugs and disease states. Specific antiserotonins block smooth muscle contraction and vasoconstriction and inhibit the action of serotonin in the brain. Some antiserotonins are used to treat vascular headaches and allergic disorders. Examples of these drugs include cyproheptadine (Periactin), lysergic acid diethylamide (LSD), and methysergide maleate (Sansert).

SECTION SEVEN
Drugs That Affect the Gastrointestinal System

REVIEW OF ANATOMY AND PHYSIOLOGY

As described in Chapter 10, the gastrointestinal system is composed of the digestive tract, the biliary system, and the pancreas. The primary function of the gastrointestinal system is to provide the body with water, electrolytes, and other nutrients used by cells. Drug therapy for the gastrointestinal system can be divided into two groups: drugs that affect the stomach and drugs that affect the lower gastrointestinal tract. In emergency care, conditions of the stomach or gastrointestinal tract that may require drug therapy usually are limited to nausea and vomiting (Box 13-28.)

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 196-199.

Drugs That Affect the Stomach

Conditions of the stomach that may require drug therapy include hyperacidity, hypoacidity, ulcer disease, nausea, vomiting, and hypermotility.

ANTACIDS

Antacids buffer or neutralize hydrochloric acid in the stomach. They are prescribed for the relief of symptoms associated with hyperacidity. These conditions include peptic ulcer, gastritis, esophagitis, heartburn, and hiatal hernia. Common over-the-counter antacids include Alka-Seltzer, Gaviscon, and Rolaids.

ANTIFLATULENTS

Antiflatulents prevent the formation of gas in the gastrointestinal tract. Gas retention is a common condition with diverticulitis, ulcer disease, and spastic or irritable colon (see Chapter 29). These drugs sometimes are used along with antacids. Simethicone (Mylicon) is an example of an antiflatulent.

DIGESTANTS

Digestant drugs promote digestion in the gastrointestinal tract. They work by releasing small amounts of digestive enzymes in the small intestine. Examples of digestants include pancreatin (Creon) and pancrelipase (Pancrease).

EMETICS AND ANTIEMETICS

Vomiting is usually an involuntary action that is coordinated by the emetic center of the medulla. Vomiting may be initiated through the CNS as a secondary reaction to emotion, pain, or disequilibrium (motion sickness); through irritation of the mucosa of the gastrointestinal tract or bowel; or through stimulation from the chemoreceptor trigger zone of the medulla by circulating drugs and toxins (e.g., opiates or digitalis).

Emetics. Emetics induce vomiting. They rarely are administered today as part of the treatment for drug overdoses and poisonings. These drugs include apomorphine and syrup of ipecac. The treatment of drug overdoses and poisoning is addressed further in Chapter 34.

Antiemetics. Drugs used to treat nausea and vomiting include antagonists of histamine, acetylcholine, and dopamine as well as other drugs. These drugs work best when they are given before rather than after nausea and vomiting have begun. For example, drugs used to treat motion sickness or vertigo should be taken 30 minutes before traveling. Common antiemetics include scopolamine (Transderm-Scōp), dimenhydrinate (Dramamine), ***diphenhydramine*** (Benadryl), ***hydroxyzine*** (Vistaril), meclizine (Antivert), ***promethazine*** (Phenergan), prochlorperazine (Compazine), and ***ondansetron*** (Zofran).

NOTE
Cannabinoids are drugs that are derived from hemp plants. They have been used experimentally to prevent vomiting in patients who receive cancer chemotherapy. Examples of these drugs include dronabinol (Marinol) and nabilone (Cesamet). These drugs use a synthetic derivative of the active ingredient in marijuana.

BOX 13-28 Emergency Drugs: Gastrointestinal System

Activated charcoal
Diphenhydramine (Benadryl)
Hydroxyzine (Vistaril)
Metoclopramide (Reglan)
Ondansetron (Zofran)
Prochlorperazine (Compazine)
Promethazine (Phenergan)

SHOW ME THE EVIDENCE
Researchers in Oregon investigated the effect of ondansetron (Zofran). In the 6 months of data collection, they evaluated the effect of administration of this drug to 952 EMS patients who had nausea and vomiting. They found no adverse effects. Vomiting decreased significantly in 462 patients (from 60% to 30%). They concluded that ondansetron was moderately effective. The researchers recommended further studies to compare this drug to other antiemetics.

From Warden CR, Moreno R, Daya M: Prospective evaluation of ondansetron for undifferentiated nausea and vomiting in the prehospital setting, *PEC* 12(1):87-91, 2008.

CYTOPROTECTIVE AGENTS

Cytoprotective agents are drugs that protect cells from damage. They are used along with other drugs to treat peptic ulcer disease by protecting the gastric mucosa. Examples of these drugs include sucralfate (Carafate) and misoprostol (Cytotec).

H_2-RECEPTOR ANTAGONISTS

As described previously, the action of histamine is mediated through H_2 receptors. Histamine has been associated with gastric acid secretion. H_2-receptor antagonists block the H_2 receptors. They reduce the volume of gastric acid secretion and its acid content. Examples of H_2-receptor antagonists include cimetidine (Tagamet), ranitidine (Zantac), and famotidine (Pepcid).

PROTON PUMP INHIBITORS

Proton pump inhibitors are used for treatment of symptomatic gastroesophageal reflux disease, short-term treatment of erosive esophagitis, and maintenance of erosive esophagitis healing. Some agents also are approved for use with antibiotics to treat *Helicobacter pylori* infection (associated with duodenal ulcers). The proton pump (potassium adenosine triphosphate enzyme system) is the final pathway for secretion of hydrochloric acid by the parietal cells of the stomach. Proton pump inhibitors decrease hydrochloric acid secretion by inhibiting the actions of the parietal cells. In addition, the gastric pH of the stomach is altered. Examples of proton pump inhibitors include esomeprazole (Nexium), lansoprazole (Prevacid), omeprazole (Prilosec), pantoprazole (Protonix), and rabeprazole (AcipHex).

Drugs That Affect the Lower Gastrointestinal Tract

Constipation and diarrhea are two common conditions of the lower gastrointestinal tract. Both conditions may require drug therapy. Drugs used to manage these conditions include laxatives and antidiarrheals.

LAXATIVES

Laxatives produce defecation. They are used to evacuate the bowel and to soften hardened stool for easier passage. Situations that may indicate the need for laxative use include the following:

- Constipation
- Neurological diseases (e.g., multiple sclerosis or Parkinson's disease)
- Pregnancy
- Rectal disorders
- Drug poisoning
- Surgery and endoscopic examination

Numerous types of laxatives are available. Many can be purchased without a prescription. Examples include saline laxatives (Epsom salt, Milk of Magnesia), stimulant laxatives (Dulcolax, castor oil, Ex-Lax), bulk-forming laxatives (Mitrolan, Metamucil), lubricant laxatives (mineral oil), fecal moistening agents (Colace, glycerin suppositories), and those used for bowel evacuation (GoLYTELY, Chronulac). Regular or excessive use of laxatives is common in older adults and in those with eating disorders. Laxative abuse may result in permanent bowel damage and electrolyte imbalance.

ANTIDIARRHEAL DRUGS

Antidiarrheal drugs are used to reduce an abnormal frequency of bowel evacuation. Common causes of acute and chronic diarrhea include bacterial or viral invasion, drugs, diet, and numerous disease states (e.g., diabetes insipidus and inflammatory bowel syndromes). Drugs used to treat diarrhea include the following:

- Adsorbents
  Bismuth subsalicylate (Pepto-Bismol)
- Anticholinergics
  Donnatal
- Opiates
  Paregoric
  Codeine
- Other agents
  Diphenoxylate (Lomotil)
  Loperamide (Imodium)

SECTION EIGHT
Drugs That Affect the Eye and Ear

TREATMENT OF EYE DISORDERS

Drugs That Affect the Eye

Drugs used to treat eye disorders include antiglaucoma agents, mydriatics and cycloplegics, antiinfective/antiinflammatory agents, and topical anesthetics.

ANTIGLAUCOMA AGENTS

Glaucoma is an eye disease in which the pressure of the fluid in the eye is abnormally high (see Chapter 23). The pressure is so high that it causes compression or obstruction of the small internal blood vessels of the eye, the fibers of the optic nerve, or both. The result is nerve fiber destruction and partial or complete loss of vision. Glaucoma is a common eye disorder in persons over age 60 and is responsible for 15% of blindness in adults in the United States.[11] Agents used to reduce the pressure in chronic glaucoma include cholinergic and anticholinesterase drugs. Some of these drugs (e.g., pilocarpine) dilate the pupil of the eye, and some constrict the pupil; others (e.g., acetazolamide) slow the secretion of aqueous fluid. If these drug therapies fail, surgery may be indicated. If glaucoma is diagnosed early, drugs can control it for a lifetime. Most physicians recommend testing for glaucoma every 2 years after age 35.

MYDRIATIC AND CYCLOPLEGIC AGENTS

Mydriatic and cycloplegic agents are applied topically. They cause dilation of the pupils and paralysis of accommodation to light. They are used to treat inflammation and to relieve ocular pain by helping the eye to rest. These drugs are used during routine eye examinations and in ocular surgery as well. Examples of these drugs include atropine ophthalmic solution, cyclopentolate hydrochloride ophthalmic solution (Cyclogyl), homatropine ophthalmic solution (Isopto Homatropine), epinephrine, and oxymetazoline (OcuClear).

CRITICAL THINKING

You are caring for an older adult patient. This patient had mydriatic eye drops instilled by an ophthalmologist. If you did not know this history, what might you consider after your physical examination of this patient?

ANTIINFECTIVE/ANTIINFLAMMATORY AGENTS

Antiinfective and antiinflammatory agents are used to treat eye conditions such as conjunctivitis, stye, and keratitis (corneal inflammation caused by bacterial infection). Examples of these drugs include bacitracin (Baciguent), chloramphenicol (Chloroptic), erythromycin (Ilotycin), and natamycin (Natacyn).

TOPICAL ANESTHETIC AGENTS

Local anesthetics are used to prevent pain in surgical procedures and eye examinations. They also are used in the treatment of some eye injuries (e.g., a corneal abrasion). These drugs usually have a rapid onset (within 20 seconds) and last 15 to 20 minutes. Examples of these drugs include proparacaine (Ophthaine, Alcaine) and ***tetracaine*** (Ak-T-Caine, Pontocaine). Other eye medications include artificial tear solutions and lubricants to provide additional moisture, irrigation solutions, and antiallergic agents to relieve symptoms of itching, tearing, and redness. Many of these drugs and solutions are available without a prescription.

Drugs That Affect the Ear

Drugs used to treat disorders of the external ear canal include antibiotics, steroid/antibiotic combinations, and miscellaneous preparations. These drugs include the following:

- Antibiotics used to treat infections
  - Chloramphenicol (Chloromycetin Otic)
  - Gentamicin sulfate (Garamycin)
- Steroid/antibiotic combinations used to treat superficial bacterial infections
  - Neomycin sulfate/polymyxin B sulfate/hydrocortisone (Cortisporin Otic)
  - Neomycin/colistin/hydrocortisone (Coly-Mycin S Otic)
- Miscellaneous preparations used to treat earwax accumulation, inflammation, pain, fungal infections, and other minor conditions
  - Boric acid in isopropyl alcohol (Aurocaine 2)
  - Triethanolamine with chlorobutanol in propylene glycol (Cerumenex)

Persons with inner ear infections or serious illness associated with hearing impairment may require antibiotics with systemic effects, following physician evaluation. These actions will help to prevent complications (see Chapter 23).

SECTION NINE
Drugs That Affect the Endocrine System

REVIEW OF ANATOMY AND PHYSIOLOGY

The endocrine system works to control and integrate body functions. (Box 13-29 presents emergency drugs that affect the endocrine system.) Information from various parts of the body is carried via blood-borne hormones to distant sites. Hormones are natural chemical substances. They act after they have been secreted into the bloodstream from endocrine glands (ductless glands that secrete internally). These glands include the anterior and posterior pituitary, thyroid, parathyroid, and adrenal glands and the thymus, pancreas, testes, and ovaries. Hormones from the various endocrine glands work together to regulate vital processes, including the following:

- Secretory and motor activities of the digestive tract
- Energy production
- Composition and volume of extracellular fluid
- Adaptation (e.g., acclimatization and immunity)
- Growth and development
- Reproduction and lactation

LOOK AGAIN

See Chapter 10: Review of Human Systems, pp. 177-178.

Drugs That Affect the Pituitary Gland

As described in Chapter 10, the hormones of the anterior and posterior pituitary gland are important for regulating the secretion of other hormones in the body. Box 13-30 lists

BOX 13-29 Emergency Drugs: Endocrine System

Dexamethasone (Decadron)
Dextrose 50%
Glucagon
Insulin
Methylprednisolone (Solu-Medrol)
Oxytocin (Pitocin, Syntocinon)

BOX 13-30 Drugs That Affect the Anterior and Posterior Pituitary Gland

Anterior Pituitary Gland Drugs
Used to treat growth failure in children caused by growth hormone deficiency:
Somatrem (Protropin)
Somatropin (Humatrope)

Posterior Pituitary Gland Drugs
Used to treat the symptoms of diabetes insipidus resulting from antidiuretic hormone deficiency:
Vasopressin (Pitressin)

BOX 13-31 Drugs That Affect the Thyroid and Parathyroid Glands

Thyroid Drugs
Used to treat hypothyroidism and to prevent goiters:
Thyroxine
Iodine products
Levothyroxine (Synthroid, Levoxyl)

Parathyroid Drugs
Used to treat hyperparathyroidism:
Vitamin D
Calcium supplements

drugs that affect the anterior and posterior pituitary. (Disorders of the endocrine glands are described further in Chapter 26.)

Drugs That Affect the Thyroid and Parathyroid Glands

The thyroid hormone controls the rate of metabolic processes and is required for normal growth and development. Parathyroid hormone regulates the level of ionized calcium in the blood. Parathyroid hormone does this through the release of calcium from bone, the absorption of calcium from the intestine, and the regulation of calcium excretion by the kidneys.

Disorders of the thyroid gland include goiter (enlargement of the thyroid gland), hypothyroidism (thyroid hormone deficiency), and hyperthyroidism (thyroid hormone excess). Disorders of the parathyroid include hypoparathyroidism and hyperparathyroidism. Box 13-31 lists the drugs used to treat these disorders (see Chapter 26).

Drugs That Affect the Adrenal Cortex

The adrenal cortex secretes three major classes of steroid hormones: glucocorticoids (cortisol), mineralocorticoids (primarily aldosterone), and sex hormones. Glucocorticoids raise blood glucose level, deplete tissue proteins, and suppress the inflammatory reaction. Mineralocorticoids regulate electrolyte and water balance. Sex hormones are estrogen, progesterone, and testosterone and are produced in small amounts by men and women. The sex hormones have little physiological effect under normal circumstances. Box 13-32 lists drugs that affect the adrenal cortex. Two disorders of the adrenal cortex are Addison's disease (adrenal cortical hypofunction) and Cushing's disease (adrenal cortical hyperfunction) (see Chapter 26).

BOX 13-32 Drugs That Affect the Adrenal Cortex

Glucocorticoids
Betamethasone (Celestone)
Dexamethasone (Decadron)
Methylprednisolone (Solu-Medrol)
Triamcinolone (Aristocort)

Mineralocorticoids
Desoxycorticosterone acetate (DOCA)
Fludrocortisone (Florinef)

Adrenal Steroid Inhibitors
Aminoglutethimide (Cytadren)
Metyrapone (Metopirone)

Drugs That Affect the Pancreas

As described in Chapter 10, the pancreas is an exocrine gland and an endocrine gland. The exocrine portion secretes hormones into ducts, providing digestive juices to the small intestine. The endocrine portion of the pancreas consists of pancreatic islets (islets of Langerhans). These cells produce the hormones that directly enter the circulatory system.

Hormones of the Pancreas

The pancreatic hormones play a key role in regulating the concentration of certain nutrients in the circulatory system. The pancreas secretes two major hormones: insulin and glucagon.

Insulin is the primary hormone that regulates glucose metabolism. In general, insulin increases the ability of the liver, adipose tissue, and muscle to take up and use glucose. Glucose not immediately needed for energy is stored in the skeletal muscle, liver, and other tissues. This stored form of glucose is called *glycogen*.

Glucagon mainly influences the liver, although it has some effect on skeletal muscle and adipose tissue. In general, glucagon stimulates the liver to break down glycogen so that glucose is released into the blood. Glucagon also inhibits the uptake of glucose by muscle and fat cells. The balancing action of these two hormones protects the body from hyperglycemia (high blood sugar) and hypoglycemia (low blood sugar).

This balance of hormonal actions is important when one considers the metabolic problems that can occur in

BOX 13-33 Drugs That Affect the Pancreas

Insulin Preparations

Rapid Acting
Insulin lispro (Humalog)
Insulin aspart (NovoLog)

Short Acting
Regular (Humulin R, Novolin R)

Intermediate Acting
NPH (Humulin N, Novolin N)
Lente (Humulin L, Novolin N)

Long Acting
Insulin Detemir (Levemir)
Insulin Glargine (Lantus)

Oral Hypoglycemic Agents
Glimepiride (Amaryl)
Glipizide (Glucotrol)
Glyburide (Micronase, Diabeta)
Metformin (Glucophage)
Pioglitazone (Actos)

Combination Drugs
Glyburide/metformin (Glucovance)
Glipizide/metformin (Metaglip)
Rosiglitazone/metformin (Avandamet)

Hyperglycemic Agents
Dextrose
Diazoxide (Proglycem)
Glucagon
Oral glucose (Glutose, Insta-Glucose)

diabetes mellitus. The relationship of glucagon and insulin to other hormones and substances such as ***dextrose* 50%** (D50) and ***thiamine*** (vitamin B_1) is addressed in Chapter 26. Box 13-33 lists drugs that affect the pancreas.

SECTION TEN
Drugs That Affect the Reproductive System

TREATMENT OF DISORDERS OF THE REPRODUCTIVE SYSTEM

Drugs That Affect the Female Reproductive System

Drugs that affect the female reproductive system include synthetic and natural substances such as hormones, oral contraceptives, ovulatory stimulants, and drugs used to treat infertility.

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 202-205.

FEMALE SEX HORMONES

Two main types of hormones are secreted by the ovary: estrogen and progesterone. Supplemental estrogen is indicated for estrogen deficiency or replacement, treatment of breast cancer, and as prophylaxis for osteoporosis in postmenopausal women (controversial). Progesterone (and synthetic progestins) may be used to treat hormonal imbalance, endometriosis, and specific cancers and to prevent pregnancy when used properly.

ORAL CONTRACEPTIVES

Oral contraception is the most effective form of birth control and is known as "the pill." Oral contraception is a combination of estrogen and progesterone. This combination results in the suppression of ovulation (see Chapter 31). Several types of oral contraceptives and drug combinations are available. All are nearly 100% effective in preventing pregnancy, when taken properly.

DID YOU KNOW?
Emergency contraception is a method of preventing pregnancy to be used after a contraceptive fails or after unprotected sex. It is not for routine use.[15] Emergency contraceptives (Previn and Plan B™) are also known as post-coital pills, or morning-after pills. They contain the hormones estrogen and progestin (levonorgestrel), either separately or in combination. Emergency contraceptives can reduce the chance of pregnancy when taken as directed up to 72 hours (3 days) after unprotected sex. These drugs have recently been approved by the FDA for women 17 years of age and older. They are available without prescription and do not require parental consent.

OVULATORY STIMULANTS AND INFERTILITY DRUGS

The absence of ovulation in women is *anovulation*. The condition may be pathological in women with abnormal bleeding or infertility. The condition sometimes is treated with gonadotropins, thyroid preparations, estrogen, and synthetic agents. One example of a drug used to induce ovulation and increase fertility is clomiphene citrate (Clomid).

NOTE
Certain drugs are used during labor and delivery. These drugs help to increase (oxytocin [Pitocin]) or decrease (ritodrine [Yutopar]) uterine contractility. In prehospital care, oxytocin is used to control hemorrhages that occur after the delivery of the infant and placenta (see Chapter 46).

Drugs That Affect the Male Reproductive System

The male sex hormone is testosterone. Adequate amounts of this hormone are needed for normal development and for the maintenance of male sex characteristics.

LOOK AGAIN

See Chapter 10: Review of Human Systems, pp. 201-202.

Testosterone therapy is indicated for the treatment of hormone deficiency (e.g., testicular failure), impotence, delayed puberty, female breast cancer, and anemia. The choice of dosage and length of therapy depend on the diagnosis, age of the patient, and intensity of side effects/adverse reactions. An example of an oral testosterone drug is methyltestosterone (Metandren).

NOTE

Impotence is the inability of a man to achieve or maintain an erection. This can lead to decreased sexual function. The condition afflicts as many as 30 million men in the United States.[16]

Drugs That Affect Sexual Behavior

Sexual drive (libido) can be affected by psychological, social, and physiological factors or by a combination of these. Negative effects of these factors can result in a lack of interest in sexual activity in men and women and impotence in men.

DRUGS THAT IMPAIR LIBIDO AND SEXUAL GRATIFICATION

Some drugs interfere with sympathetic nervous stimulation. At times they may cause sexual dysfunction. Drugs may interfere with the nervous system mechanisms (directly and indirectly) that are responsible for sexual arousal. Some of these drugs include antihypertensives, antihistamines, antispasmodics, sedatives and tranquilizers, antidepressants, alcohol, and barbiturates.

DRUGS THAT ENHANCE LIBIDO AND SEXUAL GRATIFICATION

A patient may change medicines (under physician supervision) to avoid drug-induced sexual dysfunction. In addition, a patient may be prescribed drugs to enhance libido and sexual gratification. Drugs that enhance sexual function include levodopa (L-dopa), tadalafil (Cialis), vardenifil (Levitra), and sildenafil citrate (Viagra).

NOTE

The administration of nitroglycerin (Nitrostat) or nitrate/nitrite medications is contraindicated in patients who have taken Cialis, Levitra, or Viagra within the previous 24 to 48 hours because the combination can cause a lethal drop in blood pressure. Other drugs that may produce untoward effects in patients taking drugs to enhance sexual gratification include some antibiotics, cimetidine, and some antihypertensive medications.[17] The paramedic should question the patient about the use of sexual enhancement drugs before administering any of these medications.

SECTION ELEVEN
Drugs Used in Neoplastic Diseases

ANTINEOPLASTIC AGENTS

Antineoplastic agents are used in cancer chemotherapy. They are used to prevent the increase of malignant cells (Box 13-34). These drugs do not directly kill tumor cells. Rather they interfere with cell reproduction or replication through various mechanisms.

NOTE

Any person who handles antineoplastic agents should be trained properly in the safety procedures. These drugs are considered cytotoxic (toxic to human cells).

Antineoplastic agents are nonselective. They are injurious to all cells in the body. Side effects from these drugs may include infection, hemorrhage, nausea and vomiting, and changes in bowel habits. Short-term toxicity from these agents may affect the pulmonary, cardiovascular, renal, and integumentary systems. Prehospital care for these patients mainly is supportive and is aimed at providing comfort measures and emotional support.

BOX 13-34 Examples of Antineoplastic Agents*

Doxorubicin (Adriamycin)
5-Fluorouracil (Adrucil)
Mechlorethamine (Mustargen)
Methotrexate (Amethopterin, MTX)
Streptozocin (Zanosar)
Cistiplatin (Platinol-AQ)
Carmustine (BCNU)
Chlorambucil (Leukeran)
Cyclophosphamide (Cytoxan)
Melphalan (Alkera)
Tamoxifen (Nolvadex)
Interferon

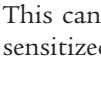
*Varies greatly, depending on the type of cancer

SECTION TWELVE
Drugs Used in Infectious Disease and Inflammation

TREATMENT OF INFECTIOUS DISEASE AND INFLAMMATION

Antibiotics

Antibiotics are used to treat local or systemic infection. Antibiotics kill or suppress the growth of microorganisms. They do this by disrupting the bacterial cell wall, by disturbing the functions of the cell membrane, or by interfering with the metabolic functions of the cell. This group of drugs includes penicillins, cephalosporins, and related products; macrolide antibiotics; tetracyclines; fluoroquinolones; and miscellaneous antibiotic agents (e.g., metronidazole [Flagyl] and spectinomycin [Trobicin]). Antibiotics are much more toxic to bacteria than they are to a patient. Some antibiotics, though, may produce hypersensitivity. This can lead to a fatal reaction if the drug is given to a sensitized patient (see Chapter 27).



NOTE

In time, some bacteria that are at first sensitive to antibiotics may become resistant to them. The bacteria develop ways to evade the effect of a drug. Widespread use and misuse of antibiotics lead to the development of resistant strains of bacteria. Bacterial resistance may even complicate treatment when a person is infected with an antibiotic-resistant organism.

PENICILLINS

Penicillins are active against gram-positive and some gram-negative bacteria (Box 13-35). Penicillins are used to treat many infections, including tonsillitis, pharyngitis, bronchitis, and pneumonia. Examples of penicillins include amoxicillin (Amoxil), ampicillin (Amcill), dicloxacillin (Dynapen), and penicillin V potassium (Pen Vee K). Penicillin can produce severe anaphylactic reactions.

CEPHALOSPORINS

Cephalosporins (and related products) resemble penicillins. Yet they are active against gram-positive and gram-negative bacteria. Cephalosporins are used widely to treat ear, throat, and respiratory tract infections. They also are useful for treating urinary tract infections. Urinary tract infections often are caused by bacteria that are resistant to penicillin-type antibiotics. Examples of cephalosporins and related products include cefazolin (Ancef), cephalothin (Keflin), cephalexin (Keflex), and cefotaxime (Claforan). About 6% to 10% of those who are allergic to penicillins are also allergic to cephalosporins.

BOX 13-35 Gram's Stain

Gram's stain is an iodine-based stain used to differentiate various types of bacteria. Examples of gram-positive bacteria are staphylococci, streptococci, and pneumococci. Examples of gram-negative bacteria are gonococci and meningococci.

MACROLIDE ANTIBIOTICS

Macrolides (erythromycins) are used to treat infections of the skin, chest, throat, and ears. Macrolides are useful for treating pertussis (whooping cough), legionnaires' disease, and pneumonia (see Chapter 28). Examples of erythromycin drugs include Eryc, EMycin, E.E.S, and Erythrocin. Other antibacterial agents include azithromycin (Zithromax) and clarithromycin (Biaxin).

TETRACYCLINES

Tetracyclines are active against many gram-negative and gram-positive organisms (*broad-spectrum*). Tetracyclines commonly are used to treat conditions such as acne, bronchitis, syphilis, gonorrhea, and certain types of pneumonia. Examples of tetracyclines include demeclocycline (Declomycin), doxycycline (Vibramycin), and tetracycline (Achromycin). Tetracyclines may discolor developing teeth. Thus they usually are not prescribed for children under the age of 12 or for pregnant women.

CRITICAL THINKING

Explain how antibiotics and infectious organisms work like a lock and key.

FLUOROQUINOLONES

Fluoroquinolone antibiotics are the treatment of choice for some human gastrointestinal infections, particularly severe food-borne illness caused by *Campylobacter* or *Salmonella* bacteria. They are also used to treat urinary tract infections, bone and joint infections, some types of pneumonia, and other human illness. Examples of fluoroquinolones include ciprofloxacin (Cipro), gatifloxacin (Tequin), and levofloxacin (Levaquin).

Antifungal and Antiviral Drugs

As discussed, persons can be infected by bacterial organisms; in addition, they can be infected by fungi and viral diseases.

ANTIFUNGAL DRUGS

Some fungi are harmlessly present at all times in areas of the body such as the mouth, skin, intestines, and vagina. These fungi are prevented from multiplying through competition from bacteria. The actions of the immune system also prevent them from multiplying. Fungal infections are more common and serious in persons taking antibiotics

long term (antibiotics destroy the bacterial competition), in those who are immunosuppressed as a complication of illness (e.g., infection with the human immunodeficiency virus), and in those who are taking corticosteroids or immunosuppressant drugs (described later in this chapter). Fungal infections can be classified broadly into superficial infections, subcutaneous infections, and deep infections (Box 13-36). Examples of antifungal drugs include tolnaftate (Tinactin), fluconazole (Diflucan), and nystatin (Mycostatin). About 50 species of fungi can cause illness and sometimes fatal disease in human beings.

NOTE
A few drugs may shorten the duration of symptoms from the influenza viruses, if taken early in the illness. These drugs include oseltamivir (Tamiflu) and zanamivir (Relenza). These drugs are effective against some A and B influenza viruses. Others include amantadine (Symmetrel) and rimantadine (Flumadine). These drugs are effective against influenza virus A (see Chapter 28).

ANTIVIRAL DRUGS

To date, few effective drugs exist to treat minor viral infections such as colds. In fact, few drugs exist for use in any viral infections. This is due partly to the relative delay in the onset of symptoms that occurs in viral diseases. This delay in turn makes drug therapy difficult once the disease is established. Some viral infections are trivial and harmless (e.g., warts). Yet others are serious diseases such as influenza, rabies, acquired immunodeficiency syndrome, and probably some types of cancers (Table 13-6).

Many agents have been tested as antiviral drugs. However, few have been proved to work against specific virus-infected cells without toxic effects to uninfected cells. Examples of specific antiviral drugs include acyclovir (Zovirax) and valacyclovir (Valtrex), which is effective against herpes infection. Others are zidovudine (Retrovir, AZT, ZDV), lamivudine (Epivir), and the combination drug lamivudine/zidovudine (Combivir). At present, these drugs are used to treat human immunodeficiency infection.

PROTEASE INHIBITORS

The complete mechanism of action of protease inhibitors is not understood clearly. Yet they appear to inhibit the replication of retroviruses (e.g., HIV) in acute and chronically infected cells. (A retrovirus is a virus that travels and tries to enter host cells with an RNA genome.) Side effects and adverse reactions of these drugs include nausea and vomiting, headache, malaise, fever, and flulike symptoms. Examples of protease inhibitors include indinavir (Crixivan), ritonavir (Norvir), and saquinavir (Invirase).

NOTE
The administration of antiviral drugs and protease inhibitors to a health care worker who has been exposed to body fluids that may contain human immunodeficiency virus or another virus known or suspected to be resistant to antiviral drugs is important and is a postexposure prophylaxis recommendation by the Centers for Disease Control and Prevention.[18]

Other Antimicrobial Drugs and Antiparasitic Drugs

Various drugs are used to treat atypical microbial infection (e.g., *Mycobacterium tuberculosis* and *M. leprae*) and infection and disease caused by parasite and insect vector (e.g., trichomoniasis and malaria). Box 13-37 lists examples of these drugs and their classifications.

BOX 13-36 Categories of Fungal Infections

Examples of Superficial Infections
Candidiasis (thrush): Affects the genitals or inside of the mouth and vaginal and intertriginous areas
Tinea (including ring worm, athlete's foot, jock itch): Affects external areas of the body

Examples of Subcutaneous Infections (Rare)
Mycetoma (Madura foot): Occurs in tropical countries
Sporotrichosis: May follow inoculation of spores through a puncture or scratch

Examples of Deep Infections
Aspergillosis
Blastomycosis
Candidiasis (that spreads from its usual site to the esophagus, urinary tract, or other internal sites)
Cryptococcosis
Histoplasmosis

TABLE 13-6 Common Viruses and Viral Diseases or Conditions

Viral Family	Diseases or Conditions
Papovavirus	Warts
Adenovirus	Cold sores, genital herpes, chickenpox, herpes zoster (shingles), congenital abnormalities (cytomegalovirus)
Picornavirus	Poliomyelitis, viral hepatitis A and B, respiratory tract infections, myocarditis, rhinovirus (common cold)
Togavirus	Yellow fever, encephalitis
Orthomyxovirus	Influenza
Paramyxovirus	Mumps, measles, rubella
Coronavirus	Common cold
Rhabdovirus	Rabies
Retrovirus	Acquired immunodeficiency syndrome, degenerative brain disease, possibly cancer

BOX 13-37 Examples of Antimicrobial and Antiparasitic Drugs

Antimalarial Agents
Chloroquine phosphate (Aralen and generics)
Hydroxychloroquine (Plaquenil and generics)
Atovaquone plus proguanil (Malarone)
Quinine (Quinamm) (plus doxycycline, tetracycline, or clindamycin)
Mefloquine (Lariam)

Antitubercular Agents
Isoniazid (Isozid, INH)
Rifampin (Rifadin)
Rifabutin
Rifapentine
Ethambutol
Pyrazinamide

Antiamebic Agents
Emetine
Iodoquinol (Yodoxin)
Paromomycin (Humatin)

Antihelminthic Agents
Diethylcarbamazine (Hetrazan)
Mebendazole (Vermox)

Antiprotozoal Agents
Metronidazole (Flagyl)

Leprostatic Agents
Clofazimine (Lamprene)
Dapsone (DDS)

Cephalosporins
Cephalexin (Keflex)
Cefazolin (Ancef)
Cefaclor (Ceclor)
Cefprozil (Cefzil)
Cefuroxime (Ceftin)
Ceftriaxone (Rocephin)
Cefdinir (Omnicef)
Cefepime (Maxipime)

Fluoroquinolones
Ciprofloxacin (Cipro)
Levofloxacin (Levaquin)
Moxifloxacin (Avelox)

Penicillins
Amoxicillin (Amoxil)
Ampicillin (Polycillin)
Dicloxacillin (Dynapen)
Penicillin G
Penicillin V

NOTE
Malaria is still a prevalent disease in tropical areas and may be carried into the United States by refugees, immigrants, and travelers. Tuberculosis is on the rise in individuals with acquired immunodeficiency syndrome. Tuberculosis also is increasing in persons who are homeless, persons who abuse drugs, and those taking immunosuppressant drugs.

Antiinflammatory and Nonsteroidal Antiinflammatory Drugs

INFLAMMATION

Inflammation is a defense mechanism of body tissues in response to physical trauma, foreign biological and chemical substances, surgery, radiation, and electricity. Regardless of the event producing inflammation, the response is similar. For example, if bacterial infection or an injury to the tissues occurs, chemical mediators are released or activated. These mediators cause vasodilation and increased blood flow (localized warmth and redness at the site). This process brings phagocytes and other leukocytes to the area. The process prevents the spread of infection by limiting the infected site. Finally, phagocytes clean the area. The damaged tissues are repaired.

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 242-245.

Inflammation can be localized or systemic. Local inflammation is confined to a specific area of the body. Symptoms include redness, heat, swelling, pain, and loss of function. Systemic inflammation occurs in many parts of the body. In addition to local symptoms at the inflammation site, red bone marrow produces and releases large numbers of neutrophils that promote phagocytosis, pyrogens stimulate fever production, and increased vascular permeability in severe cases may result in decreased blood volume. Drugs used to treat inflammation or its symptoms may be classified as analgesic-antipyretic drugs and nonsteroidal antiinflammatory drugs (NSAIDs). A number of medications have both properties.

ANALGESIC-ANTIPYRETIC DRUGS

An antipyretic drug is one that reduces fever. The temperature-regulating mechanism of the body is located in the anterior hypothalamus. (This is known as the thermostat of the body.) Normally, the set point of this hypothalamic center is about 98.6° F (37° C). When an inflammatory response occurs in the body, endogenous pyrogens are released by the phagocytic leukocytes. This produces fever. Analgesic-antipyretic drugs work by reversing the effect of the pyrogen on the hypothalamus. Thus the set point of the hypothalamus is returned to normal. The analgesic effects of these drugs act on peripheral pain

receptors to block activation. Examples of these drugs include the following:

- Acetaminophen (Datril, Tylenol, Panadol, and others)
- ***Aspirin***/acetylsalicylic acid (A.S.A, Aspergum, Bayer Aspirin, and others)
- ***Aspirin*** (buffered) (Aluprin, Bufferin, Alka-Seltzer, and others)

NONSTEROIDAL ANTIINFLAMMATORY DRUGS

Aspirin is the prototype of the nonsteroidal antiinflammatory drug. New drugs also have been developed, and like ***aspirin*** they are analgesic, antipyretic, and antiinflammatory. These drugs often are prescribed for patients with various inflammatory conditions. (One such condition is rheumatoid arthritis.) The new drugs also often are prescribed for those who cannot tolerate ***aspirin.*** In addition, these drugs may be used to treat painful joint disorders (with or without inflammation) such as osteoarthritis, low back pain, and gout. One should note that like ***aspirin,*** the other nonsteroidal antiinflammatory agents may decrease platelet activity. This could result in gastrointestinal bleeding. Long-term use of some NSAIDs has been linked to an increased risk for heart attack and stroke[19] (see Chapter 33).

NOTE
Gout is a metabolic disease associated with high levels of uric acid in the blood (hyperuricemia). Gout is characterized by attacks of acute pain, swelling, and tenderness of joints. The condition is treated with uricosuric drugs, colchicine, and nonsteroidal antiinflammatory drugs.

Nonsteroidal antiinflammatory drugs are thought to act by inhibiting specific enzymes so that prostaglandins (substances that promote inflammation and pain) are not formed. Examples of these drugs include the following:

- ***Aspirin*** (Bayer Timed-Release, Bufferin, and others)
- Diflunisal (Dolobid)
- Ibuprofen (Advil, Motrin, Nuprin, and others)
- Indomethacin (Indocin and others)
- Naproxen (Anaprox, Aleve, Naprosyn)
- Sulindac (Clinoril)
- ***Ketorolac*** (Toradol)
- Cyclooxygenase-2 inhibitors (COX-2 inhibitors)
  Celecoxib (Celebrex)
  Valdecoxib (Bextra)

SECTION THIRTEEN
Drugs That Affect the Immunological System

REVIEW OF ANATOMY AND PHYSIOLOGY

As described earlier in this chapter and in Chapter 11, the immunological system is composed of cells and organs. These cells and organs defend the body against invasion by foreign substances. Organs and tissues of the immune system include the spleen, tonsils, lymph nodes, and thymus (Figure 13-12).

LOOK AGAIN
See Chapter 10: Review of Human Systems, pp. 242-247.

Drugs Used to Treat the Immune System

IMMUNOSUPPRESSANTS

Immunosuppressant drugs reduce the activity of the immune system. They do this by suppressing the production and activity of lymphocytes. These drugs are given after transplant surgery to help prevent the rejection of foreign tissues. They also are administered to halt the progress of autoimmune disorders when other treatments are ineffective. Examples of immunosuppressant drugs include antirejection drugs (used in organ transplantation), anticancer drugs, and corticosteroids.

CRITICAL THINKING
It would be important to know that a patient with altered level of consciousness is taking an immunosuppressant drug. Why is this?

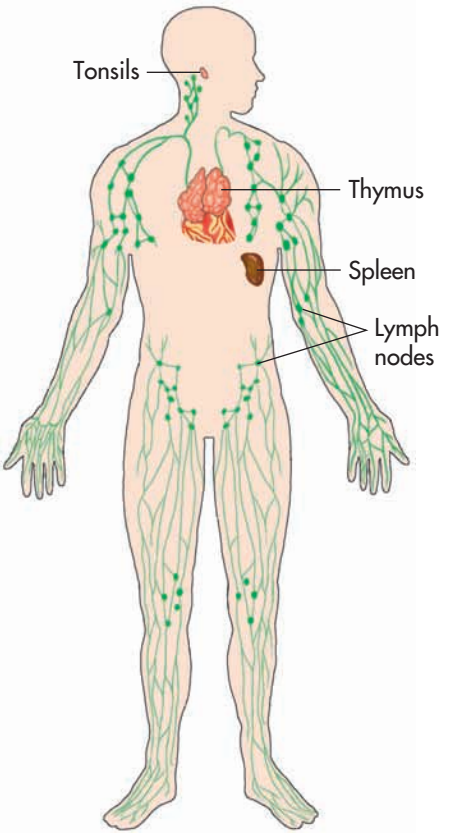


FIGURE 13-12 Organs and tissues of the immune system. (From Clayton BD, Stock YN, Harroun RD: *Basic pharmacology for nurses,* ed 14, St Louis, 2007, Mosby.)

IMMUNOMODULATING AGENTS

Immunomodulating agents are drugs that increase the efficiency of the immune system. These agents activate the immune defenses or modify a biological response to an unwanted stimulus. These drugs include vaccines that protect against specific infectious agents. One group of drugs belonging to this group is the interferons. (They are used to treat viral infections such as hepatitis C and certain types of cancer.) Another drug in this group is zidovudine (AZT, Retrovir). (Zidovudine is used to treat acquired immunodeficiency syndrome.) Some immunomodulating agents enhance the ability of a vaccine to stimulate the immune system. Thus they are added to the vaccine for this reason (see Chapter 28).

SERUMS AND VACCINES

Serum is the clear fluid that separates from blood when blood clots. Serum contains salts, glucose, and proteins. Serum also includes antibodies formed by the immune system. Antibodies are formed to fight against infection. Serum from the blood of a person (or in rare cases an animal) infected with a microorganism usually contains antibodies. Therefore that serum may protect against that microorganism if the serum is injected into someone else. This relationship forms the basis for passive immunization (see Chapter 28).

NOTE

The two main types of immunization are *passive* and *active*. In passive immunization, antibodies are injected into a person. The antibodies provide instant but short-lived protection against specific disease-causing bacteria, viruses, or toxins. Active immunization stimulates the body to make its own antibodies. These antibodies fight against such microorganisms and confer longer-lasting immunity.

Vaccines contain killed or modified microorganisms (live attenuated organisms) that usually do not cause the disease. The vaccines are given to a person to produce specific immunity. This immunity may be for a disease-causing bacterial toxin, virus, or bacterium (active immunization). The infectious agent may invade the body at a later time. At that time, the sensitized immune system quickly produces antibodies to destroy the agent or the toxin it produces. Examples of live attenuated vaccines are those given to protect against measles, mumps, rubella, yellow fever, and polio. Diphtheria and tetanus vaccines contain inactivated bacterial toxins. Cholera, typhoid fever, pertussis, rabies, viral hepatitis B, influenza, and Salk injected polio vaccines contain killed organisms. (In the case of hepatitis B the vaccine contains only part of the hepatitis B virus. See Chapter 28.)

DID YOU KNOW?

Immune Globulin

Immune globulin (IG) is a sterilized solution obtained from pooled human blood plasma that contains the immunoglobulins (or antibodies) required for protection against infectious agents that cause various diseases. Antibodies are substances in the blood plasma that fight infections. Our bodies create antibodies (or immunity) against disease-causing agents when infections occur. These antibodies can protect us from becoming ill if we are exposed to the same infectious agents sometime in the future. When someone is given IG, that person is using other people's antibodies to help fight or prevent an illness from occurring. This protection is temporary and should not be confused with getting an immunization, which provides longer-term protection.

Special IG formulations are produced from donors with high levels of antibodies against hepatitis B (hepatitis B immune globulin, HBIG), rabies (rabies immune globulin, RIG), tetanus (tetanus immune globulin, TIG), and varicella (chickenpox) (varicella-zoster immune globulin, VZIG). Immune globulins are sometimes called gamma globulins or immune serum globulins. IG administered by injection persists in the body for several months. The protective effect of the injection disappears after approximately 3 months. If risk of exposure to disease continues, individuals may require additional IG.

From Public Health Department, Seattle and King County: *Important information about immune globulins (IG) for the prevention of communicable disease,* available at http://depts.washington.edu/druginfo/Vaccine/HealthDept/ImmuneGlobulin.html, accessed 5-13-09.

SUMMARY

- A drug is any substance taken by mouth; injected into a muscle, blood vessel, or cavity of the body; or applied topically to treat or prevent a disease or condition.
- Drugs can be identified by four types of names. These include the chemical name; generic or nonproprietary name; trade, brand, or proprietary name; and official name.
- The Drug Enforcement Agency is the sole legal drug enforcement body in the United States. Other regulatory bodies or services include the FDA; the Public Health Service; the Federal Trade Commission; in Canada, the Health Protection Branch of the Department of National Health and Welfare; and for international drug control, the International Narcotics Control Board.
- Drugs do not confer any new functions to a tissue or organ; they only modify existing functions. A drug that interacts with a receptor to stimulate a response is known as an agonist. A drug that attaches to a receptor but does not stimulate a response is called an antagonist.

Continued

- Pharmacokinetics is the study of how the body handles a drug over a period of time.
- The degree to which drugs attain pharmacological activity depends partly on the rate and extent to which they are absorbed. Absorption in turn depends on the ability of the drug to cross the cell membrane. The rate and extent of absorption depend on the nature of the cell membrane the drug must cross, blood flow to the site of administration, solubility of the drug, pH of the drug environment, drug concentration, and drug dosage form.
- The route of drug administration influences drug absorption. These routes can be classified as enteral, parenteral, pulmonary, and topical.
- Distribution is the transport of a drug through the bloodstream to various tissues of the body and ultimately to its site of action. After absorption and distribution, the body eliminates most drugs. The body first biotransforms the drug and then excretes the drug. The kidney is the primary organ for excretion; however, the intestine, lungs, and mammary, sweat, and salivary glands also may be involved.
- The blood-brain barrier and the placenta are barriers to distribution of some drugs.
- Many factors can alter the response to drug therapy, including age, body mass, gender, pathological state, time of administration, genetic factors, and psychological factors.
- Most drug actions are thought to result from a chemical interaction. This interaction is between the drug and various receptors throughout the body. The most common form of drug action is the drug-receptor interaction.
- Many variables can influence drug interactions, including intestinal absorption, competition for plasma protein binding, biotransformation, action at the receptor site, renal excretion, and alteration of electrolyte balance.
- Paramedics are held responsible for the safe and effective administration of drugs. In fact, they are responsible for each drug they provide to a patient. They are legally, morally, and ethically responsible.
- Elements of the drug profile the paramedic should know include the following: drug names, classification, mechanism of action, indications, pharmacokinetics, side/adverse effects, dose, route of administration, contraindications, special considerations, and storage requirements.
- Alterations in drug administration may be needed when caring for children, pregnant patients, or older adults.
- Autonomic drugs mimic or block the effects of the sympathetic and parasympathetic divisions of the autonomic nervous system. These drugs are classified into four groups: cholinergic (parasympathomimetic) drugs, cholinergic blocking (parasympatholytic) drugs, adrenergic (sympathomimetic) drugs, and adrenergic blocking (sympatholytic) drugs.
- Narcotic analgesics relieve pain. Narcotic antagonists reverse the narcotic effects of some analgesics. Nonnarcotic analgesics interfere with local mediators released when tissue is damaged in the periphery of the body. These mediators stimulate nerve endings and cause pain.
- Anesthetic drugs are CNS depressants that have a reversible effect on nervous tissue. Antianxiety agents are used to reduce feelings of apprehension, nervousness, worry, or fearfulness. Sedatives and hypnotics are drugs that depress the CNS. They produce a calming effect. They also help induce sleep. Alcohol is a general CNS depressant that can produce sedation, sleep, and anesthesia.
- Antianxiety agents are used to reduce feelings of apprehension, nervousness, worry, or fearfulness. Sedatives and hypnotics are drugs that depress the CNS, produce a calming effect, and help induce sleep. Alcohol has characteristics of both of these drug groups.
- Anticonvulsant drugs are used to treat seizure disorders. Most notably they treat epilepsy.
- All CNS stimulants work to increase excitability. They do this by blocking the activity of inhibitory neurons or their respective neurotransmitters or by enhancing the production of the excitatory neurotransmitters.
- Psychotherapeutic drugs include antipsychotic agents, antidepressants, and lithium. These drugs are used to treat psychoses and affective disorders, especially schizophrenia, depression, and mania.
- Movement disorders such as Parkinson's disease can result from an imbalance of dopamine and acetylcholine. Drugs that inhibit or block acetylcholine are referred to as anticholinergic. Three classes of drugs affect brain dopamine levels: those that release dopamine, those that increase brain levels of dopamine, and dopaminergic agonists.
- Skeletal muscle relaxants can be classified as central acting, direct acting, and neuromuscular blockers.
- Cardiac drugs are classified by their effects on specialized cardiac tissues. Cardiac glycosides are used to treat congestive heart failure and certain tachycardias. Antidysrhythmic drugs are used to treat and prevent disorders of cardiac rhythm. The pharmacological agents that suppress dysrhythmias may do so by direct action on the cardiac cell membrane (lidocaine), by indirect action that affects the cell (propranolol), or both. The four classes of antidysrhythmic drugs are sodium channel blockers, beta blockers, potassium channel blockers, and calcium channel blockers.
- Antihypertensive drugs used to reduce blood pressure are classified into six major categories: diuretics, sympathetic blocking agents (sympatholytic drugs), vasodilators, calcium channel blockers, angiotensin-converting

enzyme (ACE) inhibitors, and angiotensin II receptor antagonists.

- Antihemorrheologic agents are used to treat peripheral vascular disorders. These disorders are caused by pathological or physiological obstruction (e.g., arteriosclerosis). These agents improve blood flow to ischemic tissues.
- Drugs that affect blood coagulation may be classified as antiplatelet, anticoagulant, or fibrinolytic agents. Drugs that interfere with platelet aggregation are known as antiplatelet or antithrombic drugs. Anticoagulant drug therapy is designed to prevent intravascular thrombosis. The therapy decreases blood coagulability. Fibrinolytic drugs dissolve clots after their formation. These drugs work by promoting the breakdown of fibrin.
- Hemophilia is a group of hereditary bleeding disorders. These disorders involve a deficiency of one of the factors needed for the coagulation of blood. Replacing the missing clotting factor can help manage hemophilia.
- Hemostatic agents accelerate clot formation, thus reducing bleeding. Systemic hemostatic agents are used to control blood loss after surgery. They work by inhibiting the breakdown of fibrin. Topical hemostatic agents are used to control capillary bleeding. They are used during surgical and dental procedures.
- The treatment of choice in managing a loss of blood or blood components is to replace the blood component that is deficient. Replacement therapy may include transfusing whole blood (rare), packed red blood cells, fresh-frozen plasma, plasma expanders, platelets, cryoprecipitate, fibrinogen, albumin, or gamma globulins.
- Antihyperlipidemic drugs sometimes are used along with diet and exercise to control serum lipid levels, which may include high levels of cholesterol and triglycerides.
- Bronchodilator drugs are the primary form of treatment for obstructive pulmonary disease such as asthma, chronic bronchitis, and emphysema. These drugs may be classified as sympathomimetic drugs and xanthine derivatives.
- Mucokinetic drugs are used to move respiratory secretions, excessive mucus, and sputum along the tracheobronchial tree.
- Oxygen is used chiefly to treat hypoxia and hypoxemia.
- Direct respiratory stimulant drugs act directly on the medullary center of the brain. These drugs are analeptics. They increase the rate and depth of respiration.
- A cough may be prolonged or result from an underlying disorder. In such a case, treatment with antitussive drugs may be indicated.
- The main clinical use of antihistamines is for allergic reactions. They also are used to control motion sickness or as a sedative or antiemetic.
- Drug therapy for the gastrointestinal system can be divided into drugs that affect the stomach and drugs that affect the lower gastrointestinal tract. Antacids buffer or neutralize hydrochloric acid in the stomach. Antiflatulents prevent the formation of gas in the gastrointestinal tract. Digestant drugs promote digestion in the gastrointestinal tract. They do this by releasing small amounts of hydrochloric acid in the stomach. Drugs used to treat nausea and vomiting include antagonists of histamine, acetylcholine, and dopamine as well as other drugs, the actions of which are not understood clearly.
- Cytoprotective agents and other drugs are used to treat peptic ulcer disease by protecting the gastric mucosa. H_2-receptor antagonists block the H_2 receptors. They also reduce the volume of gastric acid secretion and its acid content. Proton pump inhibitors decrease hydrochloric acid secretion by inhibiting the actions of the parietal cells.
- Two common conditions of the lower gastrointestinal tract may require drug therapy: constipation and diarrhea. Drugs used to manage these conditions include laxatives and antidiarrheals.
- Drugs used to treat eye disorders include antiglaucoma agents, mydriatics, cycloplegics, antiinfective/antiinflammatory agents, and topical anesthetics.
- Drugs used to treat disorders of the ear include antibiotics, steroid/antibiotic combinations, and miscellaneous preparations.
- The endocrine system works to control and integrate body functions. A number of drugs are used to treat disorders of the anterior and posterior pituitary, the thyroid and parathyroid glands, and the adrenal cortex.
- The pancreatic hormones play a key role in regulating the amount of certain nutrients in the circulatory system. The two main hormones secreted by the pancreas are insulin and glucagon. Imbalances in either of these may necessitate drug therapy. This therapy is meant to correct metabolic derangements. Oral hypoglycemic agents help lower blood glucose level by a variety of mechanisms.
- Drugs that affect the female reproductive system include synthetic and natural substances such as hormones (estrogen and progesterone), oral contraceptives, ovulation stimulants, and drugs used to treat infertility.
- The male sex hormone is testosterone. Adequate amounts of this hormone are needed for normal development and maintenance of male sex characteristics.
- Erectile dysfunction drugs are used to enhance sexual function.
- Antineoplastic agents are used in cancer chemotherapy to prevent the increase of malignant cells.
- Antibiotics are used to treat local or systemic infection. This group includes penicillin, cephalosporins, and related products; macrolide antibiotics; tetracyclines; fluoroquinolones; and miscellaneous antibiotic agents.
- Persons can be infected by bacterial organisms, fungi, and viruses. Examples of antifungal drugs include

Continued

tolnaftate (Tinactin), fluconazole (Diflucan), and nystatin (Mycostatin).
- Few drugs exist for use in any viral infections. One antiviral drug is acyclovir (Zovirax). This drug is effective against herpes infection. Another one is zidovudine (Retrovir, AZT), which currently is used to treat human immunodeficiency virus infection.
- Drugs used to treat inflammation or its symptoms may be classified as analgesic-antipyretic drugs and nonsteroidal antiinflammatory drugs. A number of medications have both properties.
- Immunosuppressant drugs reduce the activity of the immune system. They do this by suppressing the production and activity of lymphocytes. These drugs are prescribed after transplant surgery. They can help to prevent the rejection of foreign tissues. They also are sometimes given to halt the progress of autoimmune disorders.
- Immunomodulating agents are drugs that help the immune system to be more efficient. They do this by activating the immune defenses and by modifying a biological response to an unwanted stimulus.
- Serum contains agents of immunity. These are antibodies. The antibodies can protect against an organism if the serum is injected into someone else. This forms the basis for passive immunization. Vaccines are composed of killed or altered microorganisms. These are administered to a person to produce specific immunity to a disease-causing bacterial toxin, virus, or bacterium (active immunization).

APPENDIX

Herbal Products

The use of herbs and herbal products is common in the United States; it is estimated that nearly half of all Americans use herbs on a regular basis.[1,2] Unlike prescription drugs and over-the-counter medications, herbal products used as supplements are not regulated by the Food and Drug Administration (FDA). Proof of product purity and accuracy in the amount of active ingredient in each pill is not required, and there are no standards on the accuracy and amount of information that must be provided on the label of herbal products. Some herbal products have been shown to be effective, whereas others have been shown to be ineffective. In addition, some herbs when taken internally can interact with prescription medications, producing untoward effects. Therefore all persons should advise their physician and pharmacist if they are using herbal supplements. Although there are hundreds of herbal ingredients and thousands of herbal products that can be purchased without a prescription, the following section provides information about common herbal supplements used in the United States.

Herbal Supplements

Bilberry

(Airelle, Bleaberry, Burren, Dyeberry, Huckleberry, Hurtleberry, Myrtle, Trackleberry, Whortleberry)

COMMON USES

Diarrhea; improving vision; mouth/throat inflammation.

CONTRAINDICATIONS/INTERACTIONS

May inhibit platelet aggregation; should not be used before surgery or near maternal delivery; should not be used with other drugs or herbs that might affect clotting, including aspirin, nonsteroidal antiinflammatory agents, heparin, or warfarin.

Black Cohosh

(*Actaea racemosa, Cimicifuga racemosa,* Black Snakeroot, Bugbane, Rattletop)

COMMON USES

Hot flashes and other menopausal symptoms.

CONTRAINDICATIONS/INTERACTIONS

Women with breast cancer may want to avoid black cohosh until its effects on breast tissue are understood. Individuals with liver disorders or who develop abdominal pain, dark urine, or jaundice should avoid or discontinue use. No known interactions with other drugs.

Cranberry

(Arandano, Moosebeere, Mossberry)

COMMON USES

Urinary tract disorders; susceptibility to kidney stones.

CONTRAINDICATIONS/INTERACTIONS

None noted.

Echinacea

(Black Sampson, Hedgehog, Kansas Snakeroot, Red Sunflower, Purple Cone Flower)

COMMON USES

Preventing and treating infection (especially the cold or flu); low immune status.

CONTRAINDICATIONS/INTERACTIONS

May boost certain areas of the immune system and exacerbate a person's systemic disease. Not recommended in patients with autoimmune diseases, multiple sclerosis, AIDS, HIV infection, or tuberculosis, or in transplant patients or persons taking immunosuppressive drugs (e.g., anti-HIV drugs).

Ephedra

(Ma-Huang, Desert Herb, Ephedrine)

COMMON USES

Bronchodilator; nasal decongestant; weight loss; stimulant.

CONTRAINDICATIONS/INTERACTIONS

May enhance side effects of beta blockers and MAO inhibitors. Overuse may cause hypertension. May increase blood pressure in hypertensive patients.

Evening Primrose

(Fever Plant, King's Cureall, Night Willow-Herb, Scabish, SunDrop)

COMMON USES

Premenstrual syndrome; hot flashes; inflammatory disorders; migraine headache.

CONTRAINDICATIONS/INTERACTIONS

May cause uterine contraction in pregnant women; may lower seizure threshold (increasing drug dosage

requirements) in patients with seizure disorders and in those taking phenothiazine (e.g., patients with schizophrenia).

Feverfew

(Bachelors Buttons, Featherfew)

COMMON USES

Fevers, headaches (including migraine headaches), stomach aches, toothaches, insect bites, infertility, and problems with menstruation and with labor during childbirth; psoriasis, allergies, asthma, tinnitus, rheumatoid arthritis, dizziness, nausea, and vomiting.

CONTRAINDICATIONS/INTERACTIONS

Should be avoided during pregnancy (may cause uterus to contract). No serious side effects or interactions have been noted.

Garlic

(Camphor of the Poor, Nectar of the Gods, Rust Treacle, Stinking Rose)

COMMON USES

Improving circulation; lowering blood lipid levels; hypertension; inflammatory disorders; menstrual disorders; childhood earaches; diarrhea; colds and flu symptoms; and numerous other ailments.

CONTRAINDICATIONS/INTERACTIONS

May augment anticoagulant effect and may increase bleeding time; should not be used with other drugs or herbs that might affect clotting, including aspirin, nonsteroidal antiinflammatory agents, heparin, or warfarin; should not be used before surgery or near maternal delivery.

Ginger

COMMON USES

Nausea; motion sickness; morning sickness; inflammation; indigestion.

CONTRAINDICATIONS/INTERACTIONS

May inhibit platelet aggregation (in large doses); should not be used with other drugs or herbs that might affect clotting, including aspirin, nonsteroidal antiinflammatory agents, heparin, or warfarin; should not be used before surgery or near maternal delivery.

Ginkgo Biloba

(Duck Foot, Kew, Madenhair, Silver Apricot)

COMMON USES

Memory improvement; altitude sickness; poor circulation; inflammatory disorders; impotence.

CONTRAINDICATIONS/INTERACTIONS

Augments anticoagulant effect and may increase bleeding time; should not be used with other drugs or herbs that might affect clotting, including aspirin, nonsteroidal antiinflammatory agents, heparin, or warfarin; should not be used before surgery or near maternal delivery; may lower seizure threshold in patients with seizure disorders.

Ginseng

COMMON USES

Physical and mental exhaustion; stress; viral infection; diabetes; headache.

CONTRAINDICATIONS/INTERACTIONS

May lower blood glucose levels; should not be used by persons with diabetes; may alter bleeding or clotting times; should not be used with other drugs or herbs that might affect clotting, including aspirin, nonsteroidal antiinflammatory agents, heparin, or warfarin; should not be used before surgery or near maternal delivery; may contain cardiac glycosides and should not be used by persons taking digoxin.

Grape Seed

(Activin, Oligomeric Proanthocyanidins [OPCs], Red Wine Extract)

COMMON USES

Antioxidant; chronic disease prevention; leg cramps; inflammation.

CONTRAINDICATIONS/INTERACTIONS

None noted.

Kava Kava

(Ava Pepper, Awa, Intoxicating Pepper, Kawa, Kew, Sakau, Tonga)

COMMON USES

Nervous anxiety; insomnia; stress.

CONTRAINDICATIONS/INTERACTIONS

May enhance the effects of alcohol or other sedating substances; should be avoided in persons taking antidepressants, pain medications, tranquilizers, antihistamines, and anticholinergic drugs; may antagonize the effect of dopamine and should be avoided in persons with Parkinson's disease; may increase the effects of anesthesia and should be avoided before surgery; extended use may cause discoloration of the skin, nails, and hair; chronic use may produce neurological symptoms; should be avoided in pregnant women and nursing mothers.

Milk Thistle

(Holy Thistle, Lady's Thistle, Marian Thistle, St. Mary Thistle, Silymarin)

COMMON USES

Liver disorders (alcohol or drug induced, hepatitis B, hepatitis C); breast and prostate cancer.

CONTRAINDICATIONS/INTERACTIONS

Should be avoided in persons who have allergies to ragweed, marigolds, daisies, or chrysanthemums; safety during pregnancy has not been established.

Saw Palmetto

(American Dwarf Palm, Cabbage Palm, Sabal, Shrub Palmetto)

COMMON USES

Benign prostatic hypertrophy (BPH); urinary problems.

CONTRAINDICATIONS/INTERACTIONS

May have antihormone effects; should be avoided in persons with hormone-dependent cancers and during pregnancy.

St. John's Wort

(Demon Chaser, Goatweed, Hypericum, Klamath Weed, Finasteride)

COMMON USES

Anxiety; depression; sleep disorders; viral infection.

CONTRAINDICATIONS/INTERACTIONS

May potentiate the effects of MAO inhibitors, selective serotonin reuptake inhibitors (SSRIs), and tricyclics; should not be used in persons with serious depression or suicidal tendencies; may increase levels of dopamine and norepinephrine and should be avoided in persons with hypertension; may decrease serum levels of digoxin, theophylline, reserpine, and some HIV drugs; inhibits iron absorption; may cause stomach upset, sleep disturbance; photosensitivity.

Valerian Root

(All-Heal, Amantilla, Baldrian, Capon's Tail, Heliotrope, Setwall, Vandal Root)

COMMON USES

Anxiety; stress; depression; insomnia.

CONTRAINDICATIONS/INTERACTIONS

May enhance the effects of alcohol or other sedating substances; should be avoided in persons taking antidepressants, pain medications, tranquilizers, antihistamines, anticholinergic drugs, and the herb Kava Kava; may increase the effects of anesthesia and should be avoided before surgery.

CHAPTER

14 Venous Access and Medication Administration

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Convert selected units of measurement into the household, apothecary, and metric systems.
2. Identify the steps in the calculation of drug dosages.
3. Calculate the correct volume of drug to be administered in a given situation.
4. Compute the correct rate for an infusion of drugs or intravenous fluids.
5. List measures for ensuring the safe administration of medications.
6. Describe actions paramedics should take if a medication error occurs.
7. List measures for preserving asepsis during parenteral administration of a drug.
8. Explain drug administration techniques for the enteral and parenteral routes.
9. Describe the steps for safely initiating an intravenous infusion.
10. Identify complications and adverse effects associated with intravenous access.
11. List the steps for safely initiating intravenous access.
12. Describe the steps for safely initiating an intraosseous infusion.
13. Explain drug administration techniques for percutaneous routes.
14. Identify special considerations in the administration of pharmacological agents to pediatric patients.
15. Explain the technique for obtaining a venous blood sample.
16. Describe the safe disposal of contaminated items and sharps.

KEY TERMS

air embolism The presence of air bubbles in the bloodstream.

apothecary system A system of graduated liquid volumes arranged in order of heaviness; it is based on the grain.

catheter fragment embolism The shearing or detachment of an intravenous (IV) catheter, allowing the embolus to travel in the bloodstream.

cellulitis An inflammation of the skin characterized most commonly by local heat, redness, pain, swelling, and occasionally by fever, malaise, chills, and headache.

centimeter A metric unit of length equal to $\frac{1}{100}$ of a meter, or 0.3937 inches.

deciliter A metric unit of volume equal to $\frac{1}{10}$ of a liter.

embolus A blockage or free-moving thrombus in a blood vessel.

extravasation The passage or escape of blood, serum, or lymph into the tissues.

grain The smallest unit of mass in apothecaries' weights, equal to about 65 mg.

gram A metric unit of mass equal to $\frac{1}{1000}$ of a kilogram.

hematoma formation The collection of blood or fluids at the site of injection or cannulation.

household system A common system of measurement that includes the *glass, cup, tablespoon, teaspoon, drop, quart,* and *pint.*

infiltration The process by which a fluid passes into tissues.

kilogram A metric unit of mass equal to 1000 grams, or 2.2046 pounds.

liter A metric unit of capacity equal to 1 cubic decimeter, 61.025 cubic inches, or 1.0567 liquid quarts.

medical asepsis The removal or destruction of disease-causing organisms or infected material.

meter A metric unit of length equal to 1000 millimeters.

metric system A system of measurement that includes the *meter, liter,* and *gram.*

microgram A metric unit of mass equal to $\frac{1}{1,000,000}$ of a gram.

milligram A metric unit of mass equal to $\frac{1}{1000}$ of a gram.

milliliter A metric unit of capacity equal to $\frac{1}{1000}$ of a liter.

millimeter A metric unit of length equal to 1/1,000 of a meter

necrosis The death of tissue.

phlebitis Inflammation of a vein, often accompanied by the formation of a clot; also known as thrombophlebitis.

pulmonary embolism The blockage of a pulmonary artery by foreign matter, such as fat, air, tumor tissue, or a thrombus that usually arises from a peripheral vein.

sepsis Infection.

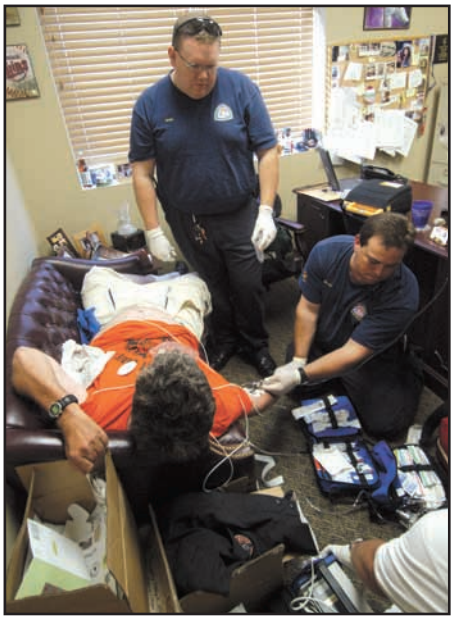
thromboembolism A condition in which a blood vessel is blocked by an embolus carried in the bloodstream from the site of formation of the clot.

thrombosis The formation of a blood clot (thrombus) in a blood vessel.

sloughing The separation of tissue.

universal precautions Infection control practices in health care, observed for every patient and procedure, that prevent exposure to blood-borne pathogens.

The ability to gain venous access safely and to administer prescribed medications are key elements of professional paramedic practice. This chapter addresses techniques for drug administration. It also emphasizes the paramedic's patient care responsibilities with regard to medication therapy.



(Courtesy Ray Kemp, St. Charles, Mo.)

NOTE

Mathematical skills are important in the administration of drugs. These skills include multiplication and division, figuring percentages, and working with Roman numerals, fractions, decimal fractions, and proportions. Paramedics must have a good working knowledge of these principles and must be adept at calculations.

MATHEMATICAL EQUIVALENTS USED IN PHARMACOLOGY

Three systems for measuring drug dosages are in common use today. These are the **metric system,** the **apothecary system,** and the common **household system** (Box 14-1). Each system deals with units of mass and volume. A physician may use any of these three systems in ordering drugs.

Metric System

The French developed the metric system of weights and measures in the latter part of the eighteenth century. Congress declared it to be the official measurement system in the United States in 1866.[1] Use of the metric system is not required in the United States. However, it has been adopted by the medical sciences and pharmacies. It is used to weigh currency at the federal mints. The military also uses it. About 92% of the countries of the world use the metric system. The International System of Units is the modern form of the metric system. It is often abbreviated as SI, from the French *Le **S**ystème **I**nternational d'Unités.*

The basic metric units of measurement are the meter, the liter, and the gram. The **meter** is the unit for linear measurement. The **liter** is the unit for capacity or volume. The **gram** is the unit for weight. A meter is slightly longer than a yard. A liter is slightly more than a quart. A gram is slightly more than the weight of a metal paper clip.

BOX 14-1 Systems of Equivalents

Metric System

1 g = 0.001 kg
1 g = 1000 mg
1 L = 1000 mL

Apothecary System

1 grain (gr) = $\frac{1}{60}$ dram (dr) or $\frac{1}{480}$ oz
60 gr = 1 dr
8 dr = 1 oz (or K)
1 minim (m) = $\frac{1}{60}$ fluid drams (f dr) or $\frac{1}{480}$ fluid ounces (f oz)
60 m = 1 f dr (or f l)
8 f dr = 1 f oz (or f K)

Household System

1 lb = 16 oz
1 pt = $\frac{1}{2}$ quart (qt) = $\frac{1}{8}$ gallon (gal)
1 pt = 16 f oz = 32 tablespoons (T)
1 T = 3 teaspoons (t)
1 t = 5 mL
1 T = 15 mL
1 pt = 480 mL
1 qt = 960 mL
1.0 gal = 3.84 L

The basic units of the metric system can be divided or multiplied by 10, 100, or 1000 parts to form secondary units. These secondary units differ from each other by 10 or some multiple of 10. Subdivisions of these basic units are made when the decimal is moved to the left. Multiples of the basic units are made when the decimal is moved to the right. The names of the secondary units are formed by putting a Greek or Latin prefix on the primary unit (Table 14-1).

The meter (m) is the unit of length from which the other metric units of length are derived (Figure 14-1). The **centimeter** (cm) and the **millimeter** (mm) are the primary linear measurements used in medicine. For example, they are used to measure the size of body organs and to measure blood pressure.

The liter (L) is the unit of capacity or volume (Figure 14-2). A fractional part of a liter is expressed in milliliters (mL) or cubic centimeters (cc). The liter is equal to 1000 mL (1000 cc). A **milliliter,** therefore, is $\frac{1}{1000}$ of a liter. A **deciliter** is $\frac{1}{10}$ of a liter. The National Bureau of Standards recommends that the units of measure *ml* or *mL* and *dl* or *dL* be used to express fractional parts of a liter.

The gram (g) is the metric unit used to weigh drugs and various pharmaceutical preparations (Figure 14-3). The gram equals the weight of 1 mL of distilled water at 4° C. A **kilogram** (kg) is equal to 1000 grams, or 2.2 pounds. A **milligram** (mg) is equal to $\frac{1}{1000}$ of a gram. A **microgram** (mcg) is equal to $\frac{1}{1,000,000}$ of a gram.

TABLE 14-1 Common Metric Prefixes

Prefix	Meaning
kilo-	1000 times greater
deci-	10 times less
centi-	100 times less
milli-	1000 times less
micro-	1 million times less

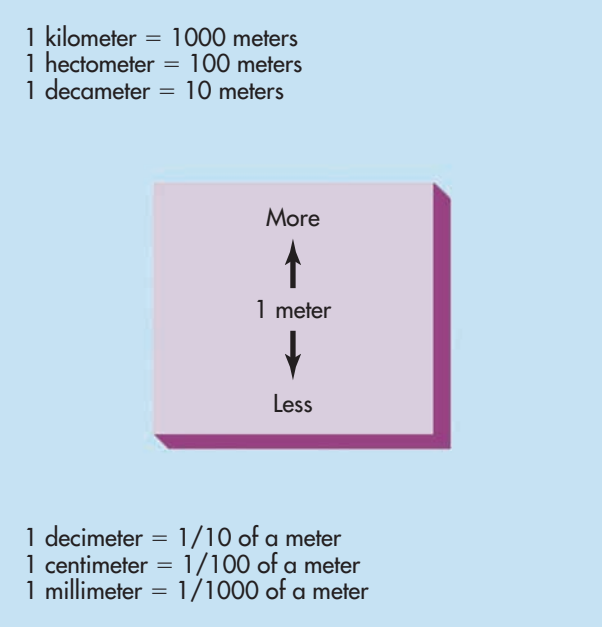


FIGURE 14-1 The *meter* measures length.

METRIC STYLE OF NOTATION

The National Bureau of Standards recommends the following style of metric notation except when it conflicts with the proper use of English[2]:

- Units are not capitalized (gram, not Gram).
- Unit abbreviations are not followed by a period (mL, not m.L. or mL.).

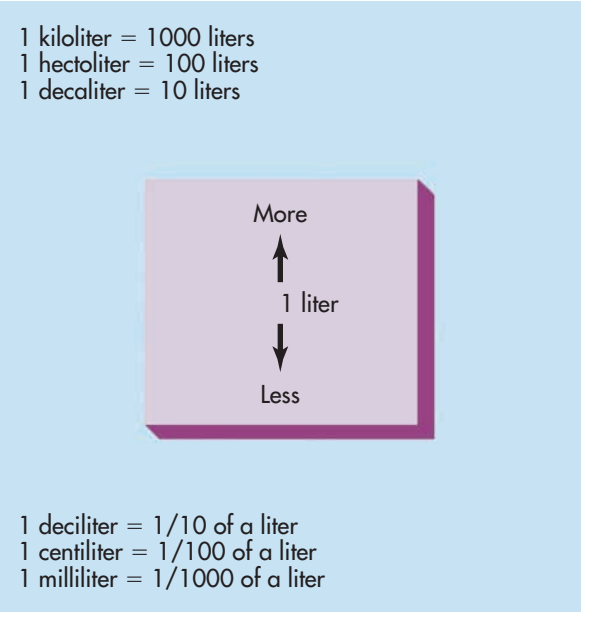

FIGURE 14-2 The *liter* measures capacity.

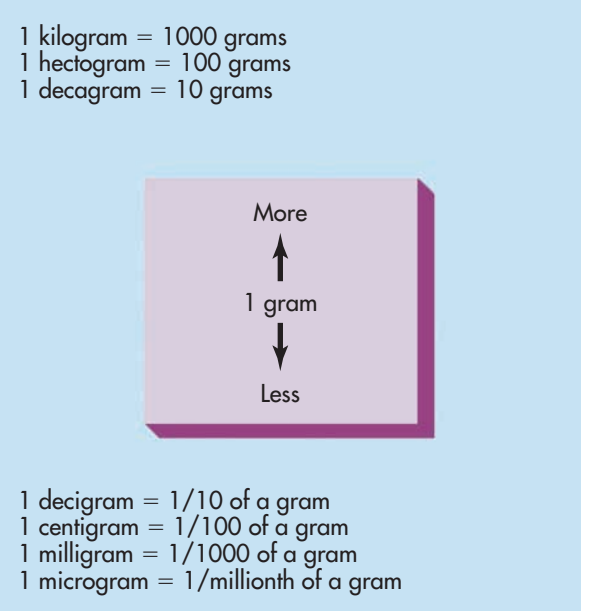

FIGURE 14-3 The *gram* measures weight.

- A single space is left between the quantity and the symbol (24 kg, not 24kg).
- Unit abbreviations are not pluralized (kg, not kgs).
- As a rule, fractions are not used, only decimal notation (0.25 kg, not ¼ kg).
- For numerical quantities less than 1, a 0 is placed to the left of the decimal point (0.75 mg, not .75 mg).
- Trailing zeros should not be used after a decimal point (2 mg, not 2.0 mg).

CRITICAL THINKING
Placing a 0 to the left of the decimal point reduces the likelihood of a drug dosing error. Why?

Apothecary System

The apothecary system is less precise and less convenient than the more widely adopted metric system. This system is seldom used in the medical sciences. Only a few medications are now available in units of the apothecary system. ***Aspirin*** and ***nitroglycerin*** are two examples.

The primary unit of mass in the apothecary system is the **grain** (gr). The grain was derived from the age-old standard of the weight of a single grain of wheat (about 60 to 65 mg). ***Aspirin*** (5 gr) contains 325 milligrams of medication (5 grain × 65 mg = 325 mg). ***Nitroglycerin*** generally is labeled with both milligrams (0.3 to 0.4 mg) and grains (1/150 or 1/200 gr). Other units of mass used in the apothecary system are the *dram* (dr), *ounce* (oz), and *pound* (lb). Sixty grains equals 1 dram, and 8 drams equals 1 ounce.

The primary unit of volume in the apothecary system is the *minim* (m). The minim equals the volume of water that would weigh 1 gr (about 0.005 or 0.006 mL). The equivalent of 60 m is 1 fluid dram (f dr), and 8 f dr equals 1 fluid ounce (f oz).

In written prescriptions, the apothecary system puts the abbreviation before the numeral. Whole numerical amounts usually are set in lower case Roman numerals. For example, 10 grains would be grains x. Fractional amounts usually are given in Arabic numerals rather than decimal form. For example, ¼ grain would be grain ¼, not 0.25 grain.

NOTE
The only apothecary conversion needed in emergency drug therapy is pounds to kilograms: 1 kilogram = 2.2 pounds. When the weight of an adult patient is converted from pounds to kilograms, the whole number can be rounded up when the number to the right of the decimal point is 5 or greater. For example, 70.9 kg could be rounded up to 71 kg.

Household System

Household measures include the *glass, cup, tablespoon, teaspoon, drop, quart,* and *pint.* Standard measures of the household system are not available in most homes. For example, the average coffee cup may hold 5 to 9 ounces or more. The average household teaspoon may hold 4 to 6 mL of liquid. Household measurements are only approximations.

Temperature Conversions

The *Fahrenheit* and *Celsius* (centigrade) temperature scales are used to measure temperature. These measurements are compared by their freezing points and their boiling points. On the Fahrenheit scale, water freezes at 32° and boils at 212°. On the Celsius scale, water freezes at 0 degree and boils at 100°. Throughout most of the world, the Celsius scale is the preferred temperature scale used in scientific and engineering fields. Most of the general population in the United States is more accustomed to the Fahrenheit scale. This is probably because the Fahrenheit scale is used by the U.S. media in weather forecasts.

Normal body temperature is 98.6° Fahrenheit, or 37° Celsius (centigrade). A simple formula can be used to convert temperatures. To convert a Celsius reading to Fahrenheit, multiply the Celsius reading by 9/5 or 1.8. Then add 32. To convert a Fahrenheit reading to Celsius, subtract 32 from the Fahrenheit reading. Then multiply by 5/9 or 0.555. (Figure 14-4).

NOTE
Remember these temperature conversion formulas:
Celsius to Fahrenheit: (° C 9/5) + 32
Fahrenheit to Celsius: (° F – 32) (5/9)

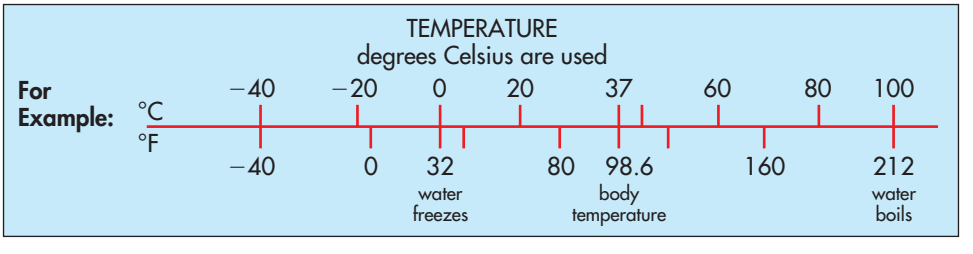

FIGURE 14-4 Temperature conversions.

DRUG CALCULATIONS

While providing emergency care, the paramedic must calculate adult and pediatric drug dosages and infusion rates, as well as the strength of drug solutions and diluted solutions. These tasks involve the use of basic math skills in a logical order. This requires a working knowledge of decimals, fractions, ratios, and proportions. This text offers common equations used for drug calculations. These equations are accepted in the medical community. Other drug calculation methods may work as well (Box 14-2).

Calculation Methods

Calculation methods must be precise and reliable. To perform drug calculations, paramedics should:

- Convert all units of measure to the same unit and system
- Check the computed dosage to determine whether it is reasonable
- Use one dosage calculation method consistently

CONVERSION OF UNITS OF MEASURE

Most emergency drug preparations do not require conversion. This is because most drugs are packaged in milligrams and administered in milligrams. However, some drugs, such as ***dopamine,*** are packaged in milligrams but administered in micrograms (mcg). These drugs must be converted to like units. When conversion to like units is required, the conversion must be completed before the drug dose is calculated.

Example

You are to administer ***dopamine*** at a rate of 800 mcg per minute. You have 200 mg of the drug in 250 mL of solution. Convert 800 mcg to 0.8 mg so that both measures of weight are in the same units:

$$800 \text{ mcg} \div 1000 = 0.8 \text{ mg}$$

CRITICAL THINKING

Imagine that you failed to convert the 800 mcg of dopamine to 0.8 mg in this example. Would you overdose or underdose your patient?

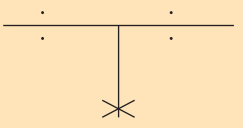
NOTE

Math tip: Move the decimal point to the right when multiplying (converting the measurement to smaller units). Move it to the left when dividing (converting the measurement to larger units).

When the dose is given per unit of weight (kg), the patient's weight must be converted from pounds to kilograms. This should be done before the total dose to be given is calculated.

BOX 14-2 "T" Method of Calculating Conversions, Drug Doses, and Intravenous Flow Rates

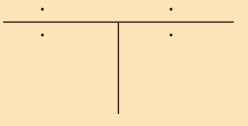
The "T" method for calculating conversions, drug doses, and intravenous (IV) flow rates does not require advanced mathematical skills. The following are guidelines for using this method to calculate a drug dose.



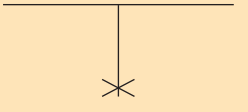
1. One T is required for every step in the calculation. To use the T method, you must know two things: (1) the prescribed dose, and (2) the gram or milligram or microgram per mL concentration of the drug.
2. The number entered on the lower right side of the T is always a "given in 1" (a known factor, such as known in 1 mL or known in 1 kg), or a multiple of 10 when converting within the metric system, that will never have to be solved for. The answer solved for in the equation will always be on top of the T or in the lower left side. The number on top of the T is always the larger number (either a known number or one to be solved for). The number in the lower left side is always the smaller number (either a known number or one to be solved for).

Larger Number	
Smaller Number	Given in 1

3. If a number is placed on top of the T, it will always be divided by the other number in the T to find the answer.



4. If both numbers are in the bottom of the T, multiplication must be performed to find the answer.



BOX 14-2 "T" Method of Calculating Conversions, Drug Doses, and Intravenous Flow Rates—cont'd

Example 1:
You are to administer meperidine 25 mg IM. You have 50 mg of the drug in 1 mL of solution. How many milliliters will you give?

Step 1:
Place the "given" (50 mg/in 1 mL) in the lower right corner of the T:

	50 mg in 1 mL

Step 2:
Place the larger number (the desired dose of 25 mg) on top of the T:

25 mg	.
	50 mg in 1 mL .

Step 3:
Divide 25 by 50 (basic formula) to obtain the smaller number (the required dose of 0.5 mL):

25 mg	.
(0.5 mL)	50 mg .

Example 2:
You are to administer lidocaine 1 mg/kg IV to a 177-pound man. You have 100 mg in 5 mL of solution. How many milliliters will you give? This calculation requires four steps (four Ts).

Step 1:
Convert the patient's weight to kilograms:

177 lb	.
(80 kg)	2.2 lb in 1 kg .

Step 2:
Calculate the prescribed dose in milligrams:

80 mg	.
1 mg ×	80 kg .

Step 3:
Determine the mg/mL concentration of the drug (remember, this example uses 5 mL of solution, not 1 mL):

100 mg	.
(20 mg per mL)	5 mL .

Step 4:
Use the basic formula to calculate the dose:

80 mg	.
(4 mL)	20 mg in 1 mL .

Example 3:
You are to administer atropine 0.02 mg/kg IV to a pediatric patient who weighs 30 pounds. You have 1 mg of the drug in 10 mL of solution. How many milliliters will you give? This calculation requires four steps (four Ts).

Step 1:
Convert the patient's weight to kilograms:

30 lb	.
(13.6 kg)	2.2 lb in 1 kg .

Step 2:
Calculate the prescribed dose in milligrams:

0.27 mg	
0.02 mg ×	13.6 kg

Step 3:
Determine the mg/mL concentration of the drug:

1 mg	
(0.1 mg/mL)	10 mL

Step 4:
Use the basic formula to calculate the dose:

0.27 mg	
(2.7 mL)	0.1 mg/ in 1 mL

Example

You are to give 1 mg/kg of ***lidocaine*** to a patient who weighs 132 lb. Divide 132 by 2.2 to convert pounds to kilograms (132 lb = 60 kg). The total dose equals 1 mg/kg multiplied by 60 kg. This equals 60 mg.

$$132\text{ lb} \div 2.2 = 60\text{ kg}$$

$$1\text{ mg/kg} \times 60\text{ kg} = 60\text{ mg}$$

ASSESSMENT OF COMPUTED DOSES

Many emergency drugs are packaged in units that contain enough drug for a normal adult dose. After computations are performed, the paramedic should decide whether the answer is reasonable.

Example

You are to administer 8 mg of ***diazepam.*** It is supplied in a 2 mL ampule that contains 10 mg of the drug. Therefore, a reasonable calculation of volume would be less than 2 mL.

METHODS OF CALCULATION

Many drug calculations can be performed almost intuitively. This is because many drugs are packaged to supply one adult dose. However, a paramedic should never rely on intuitive calculations, no matter how simple the drug dose may seem. The three methods of calculation discussed below are in common use.

METHOD 1: BASIC FORMULA ("DESIRE OVER HAVE")

For method 1, information must be substituted in the following formula:

$$\frac{D}{H} \times Q = X$$

In this formula, *D* is the desired dose to be given. *H* is the known dose on hand. *Q* is the unit of measure or volume on hand. *X* is the unit of measure to be given. Many consider "desire over have" to be the easiest formula to use. It works for nearly all emergency drug calculations.

Example

You are to administer 25 mg of ***diphenhydramine.*** You have a 10 mL vial that contains 50 mg of the drug. How many milliliters will you give? Using the "desire over have" formula, calculate the dose.

$$\frac{25\text{ mg}}{50\text{ mg}} \times 10\text{ mL} = X$$

$$\frac{25}{5} \times 1\text{ mL} = X$$

$$5 \times 1\text{ mL} = X$$

$$X = 5\text{ mL}$$

NOTE

Math tip: When using the basic formula, always divide the bottom number into the top number.

METHOD 2: RATIOS AND PROPORTIONS

Method 2 uses ratios and proportions to calculate the drug dosage. A *ratio* compares two numbers and is the same as a fraction. When used to calculate drug doses, a ratio refers to the weight or quantity of a drug in solution. For example, the ratio of 10 mg of ***morphine*** in 1 mL of solution is 10 mg to 1 mL. A *proportion* is an equation made up of two ratios; it states that the two ratios are equal. For example, $\frac{2}{3}$ is equal to $\frac{4}{6}$ (2 : 3 :: 4 : 6); therefore the ratios are equivalent and the proportions are true.

To use method 2, the equation must be set up to ensure that the same units of measure are stated in the same sequence (e.g., mg : mL = mg : *x* mL). *x* is the quantity (e.g., mL) to be solved. The formula can be expressed as

Dose on Hand : Volume on Hand :: Desired Dose : Desired Volume

Example

You are to administer 40 mg of ***furosemide.*** You have 100 mg of the drug in 10 mL of solution. How many milliliters will you give? Calculate the dose using ratios and proportions:

$$100\text{ mg} : 10\text{ mL} :: 40\text{ mg} : x\text{ mL}$$

Multiply inside numbers *(means)* and outside numbers *(extremes)*. Drop the unit of measurement terms.

$$\underset{\text{Means}}{\overset{\lceil\quad\rceil}{100\text{ mg} : 10\text{ mL} :: 40\text{ mg} : x\text{ mL}}}\ \underset{\text{Extremes}}{\lfloor\quad\rfloor}$$

NOTE

Math tip: Remember the phrases *middle for means* and *end for extremes*. In a proportion, the product of the means is always equal to the product of the extremes.

Solve the proportion by dividing both sides of the equation by the number before × (100).

$$\frac{100x}{100} \times \frac{400}{100} = 4\text{ mL}$$

To check your answer, multiply the means and then multiply the extremes. The sum product will be equal if the proportion is true.

$$\left.\begin{aligned} 100 \times 4 &= 400 \\ 10 \times 40 &= 400 \end{aligned}\right\} \text{Sum parts are equal}$$

METHOD 3: DIMENSIONAL ANALYSIS

Dimensional analysis works well for complex drug calculations. These may call for several conversions of a similar basic dimensional unit so that all units of measure are

changed to like units (e.g., milligrams). Dimensional analysis is based on the same tenet as the basic formula. However, it does not require memorization of the "desire over have" equation. All conversion factors are set up in one equation. They are separated by multiplication signs.

NOTE
Math tip: When using dimensional analysis, convert all units to the easiest math operation. This reduces the chance of error.

Example
You are to administer 0.8 mg of ***naloxone***. The drug is packaged in 1 mL of solution containing 0.4 mg of the drug.

Step 1: Set up the equation, placing the desired unit of measure in the answer to the left of the equal sign. Place the first factor to the right of the equal sign. Make sure it is the same unit as the answer.

$$\text{mL} = \frac{1\text{ mL}}{0.4\text{ mg}} \times \frac{0.8\text{ mg}}{1}$$

Step 2: Cancel like units of measure in the numerator and denominator, and reduce the fraction, if needed:

$$\text{mL} = \frac{1\text{ mL}}{0.4\ \cancel{\text{mg}}} \times \frac{0.8\ \cancel{\text{mg}}}{1}$$

NOTE
Math tip: The only unit remaining after canceling the like units should be the unit of the answer. If this is not the case, the equation is set up incorrectly.

Step 3: Multiply the numerators and then the denominators.

$$\text{mL} = \frac{1\text{ mL}}{0.4} \times \frac{0.8}{1}$$

Step 4: Divide the numerator by the denominator to solve the equation.

$$\text{mL} = \frac{0.8\text{ mL}}{0.4} = 2\text{ mL}$$

Calculating Intravenous Flow Rates

To calculate intravenous (IV) flow rates, paramedics must know three factors: (1) the volume to be infused; (2) the period of time, in minutes, over which the fluid is to be infused; and (3) the number of drops (gtt) per milliliter the infusion set delivers *(drop factor)*. The flow rate can then be calculated using the following equation:

$$\text{gtt/min} = \frac{\text{Volume to be infused} \times \text{Drop factor}}{\text{Duration of infusion (minutes)}}$$

Example
You are to give 250 mL of normal saline over 90 minutes. Your infusion set delivers 10 gtt/mL. Calculate the drops per minute using the above formula.

$$\text{gtt/min} = \frac{250\ \cancel{\text{mL}} \times 10\text{ gtt/}\cancel{\text{mL}}}{90\text{ minutes}} = \frac{2500\text{ gtt}}{90\text{ min}} = 27.7 \text{ or } 28\text{ gtt/min}$$

NOTE
The two intravenous (IV) infusion sets most often used in emergency care are microdrip tubing and macrodrip tubing. Microdrip tubing delivers 60 gtt/mL. Macrodrip tubing delivers 10, 15, or 20 gtt/mL. *Math tip:* When a drop factor of 60 is used, the gtt/min always equals the mL/hour infusion.

CRITICAL THINKING
When is it best to use microdrip tubing? When is it better to use macrodrip tubing?

Calculating Infusion Rates

Paramedics may need to administer medications by continuous IV infusion. Calculating the correct drip rate is crucial (Boxes 14-3 and 14-4). This helps prevent overdosing or underdosing of the patient. To properly calculate and give a prescribed drug by continuous infusion, paramedics must know three things: (1) the prescribed dose; (2) the concentration of the drug in 1 mL of solution; and (3) the drop factor of the IV infusion set. The calculation then is made using the following IV drip formula:

$$\text{gtt/min} = \frac{\text{Prescribed dose} \times \text{Drop factor}}{\text{Concentration of drug in 1 mL}}$$

Example
You are to administer a ***procainamide*** infusion at 3 mg/min. You have 1 g of the drug in 250 mL of 5% dextrose in water (D_5W). The infusion set delivers 60 gtt/mL. How many drops per minute will you deliver?

Convert all units to like measurements and calculate the concentration of the drug in 1 mL.

$$1\text{ g} \times 1000 = 1000\text{ mg}$$

$$1000\text{ mg} \div 250\text{ mL} = 4\text{ mg/mL}$$

Calculate the drops per minute using the IV drip formula:

$$\text{gtt/min} = \frac{3\text{ mg/min} \times 60\text{ gtt/mL}}{4\text{ mg in 1 mL}} = \frac{180}{4} = 45\text{ gtt/min}$$

Calculating Drug Dosages for Infants and Children

The doses of some medications for infants and children are administered in the same proportion to body weight as the doses for adults. Others are given in very reduced doses.

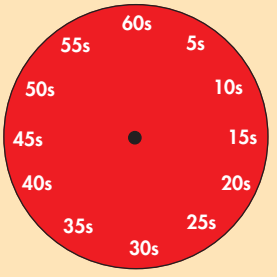
BOX 14-3 "Clock" Method of Calculating Flow Rates

Visualizing a clock can help paramedics calculate the flow rate for an intravenous (IV) medication. For example, if the concentration of a drug in solution is 4 mg/mL and microdrip tubing is used that delivers 1 mL in 60 drops, and 60 drops are delivered in 1 minute, then 4 mg will be delivered with every 60 drops of solution. Picturing a clock where 4 mg and 60 drops are at the 12 position, you can calculate that 15 drops/minute will deliver 1 mg/minute; 30 drops will deliver 2 mg/min; and 45 drops will deliver 3 mg/min. You can use this same method with any drug in solution when microdrip is used.

Lidocaine Infusion Clock

- Mix 2 g of lidocaine in 500 mL D_5W or NS (or 1 g in 250 mL) = 4 mg/mL
- Infusion dose range = 2-4 mg/min
- When administered with a minidrip (60 gtt/mL) IV administration set, lidocaine drip rates resemble a seconds "clock"

60 gtt/min = 4 mg/min



30 gtt/min = 2 mg/min

BOX 14-4 Shortcut for Calculating Dopamine Drips

Dopamine is a very strong drug. Calculating the correct dose can daunt the best mathematician. The following is a shortcut for calculating dopamine infusions using 60 drops/minute intravenous (IV) tubing and a standard mixture of drug in solution (e.g., 400 mg in 250 mL; 800 mg in 500 mL).

Formula:

$$\frac{\text{Dose} \times \text{Weight (kg)} \times 60 \text{ gtt/mL}}{1600} = \text{Drops per minute}$$

Example:

You are to administer 5 mcg/kg of dopamine per minute to a 75 kg patient.

$$\frac{5\,\mu\text{g} \times 75\,\text{kg} \times 60\,\text{gtt/mL}}{1600} = 14\ \text{Drops per minute}$$

This is due to differences in the child's ability to metabolize the drug. In general, the total dose administered to a child rarely exceeds a normal adult dose (see Chapter 13). Paramedics often calculate pediatric drug doses in the prehospital setting by using memory aids or with the advice of medical direction. Some of the memory aids are charts, tapes, pocket guides, and dosage wheels (Figure 14-5). Personal electronic devices (e.g., personal digital assistants [PDAs]) with drug calculation software also are available (Figure 14-6). The most precise way to calculate a pediatric drug dose is based on the child's body surface area. (Body surface area as a function of weight is discussed in Chapter 48.) The wisest course is to have someone double-check the dose before a medication is administered to a child.

NOTE

Paramedics who administer a medication do so by the authority provided by medical direction. The paramedic has both a professional and a legal responsibility to follow all patient management protocols, policies, and procedures. These policies specify the regulations of drug administration. This includes policies on the stocking and supply of drugs.

DRUG ADMINISTRATION

During the administration of any drug, safety should always be a high priority.

Safety Considerations and Procedures

Paramedics should follow these guidelines when administering drugs to patients.

- Focus on the procedure and avoid distractions (including when preparing the medicines).
- In the prehospital setting, carefully follow all standing orders and protocols for drug therapy. Make sure that any medication orders received from medical direction are fully understood. Repeat all orders back to medical direction for confirmation. Before administering any drug, state the *name* of the drug, the *dose,* and the *route* by which it is to be given. If the order is unclear or if there is reason to question the order, ask medical direction to repeat it. In the emergency department or other patient care areas, make sure you have a written or electronic order for every medication you administer. Verify the patient's name on the person's armband or identification tag and scan the tag (per protocol for electronic recordkeeping). Also, verify that the patient is not allergic to the medication. Strictly follow these *five patient rights* of drug administration: Make sure the *right* patient receives the *right* dose of the *right* drug via the *right* route at the *right* time. Also make sure to document the drug administration accurately and thoroughly.
- Make a habit of reading the drug label and comparing it to the medication order at least three times before administration:
  - First—when removing the drug from the drug kit or supply area

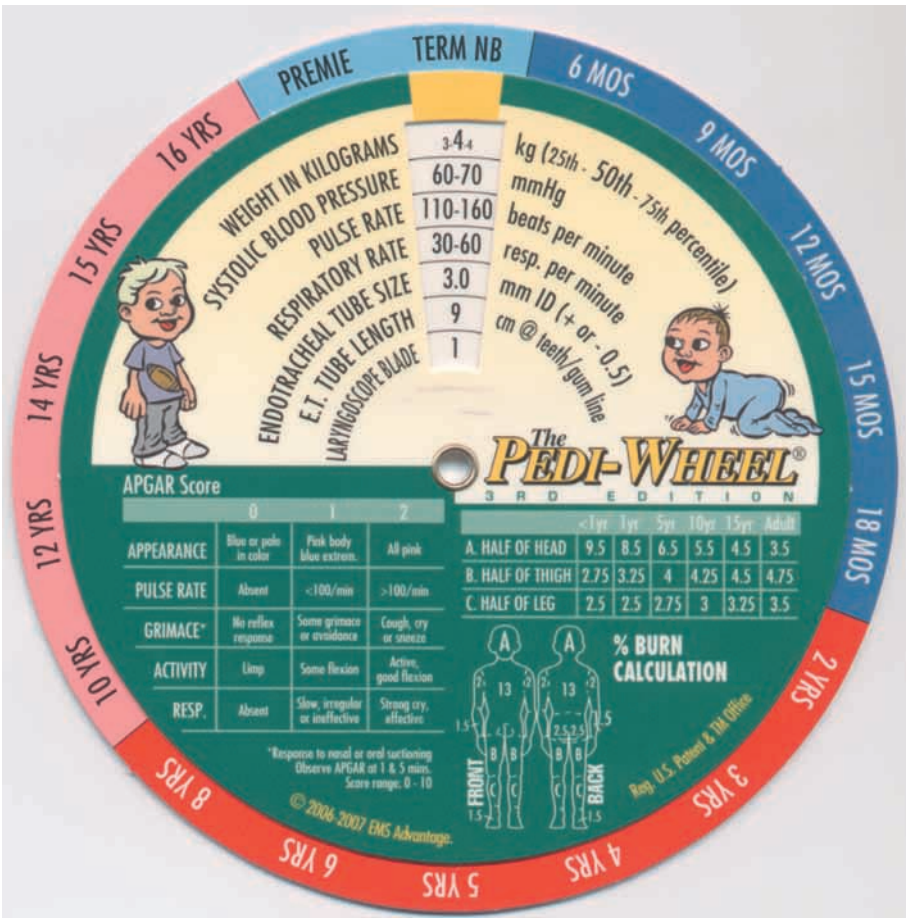


FIGURE 14-5 Pedi Wheel. (Courtesy Harley Don and 2010 EMS Advantage.)

FIGURE 14-6 Drug references are available on wireless devices. (Courtesy PEPID, Rocklin, Calif.)

  - Second—when preparing the medication for administration
  - Third—just before administering the drug to the patient (before the container is discarded)
- Always check the correct route of administration. Some medications can be prepared for administration by several routes. For instance, the route could be intramuscular or intravenous.
- Make sure the information on the label matches the prescriber's order.
- Never give a medicine from an unlabeled container. Also, never give a medicine from a container on which the label is not legible.
- If you are unsure of your drug calculation, have a coworker check it. You also can contact medical direction for verification.
- Handle multidose vials carefully and with aseptic technique. This prevents drugs from being wasted or contaminated.

NOTE
As a rule, a multidose vial should be discarded after a single patient use. Also, the safest course is to restrict each medication vial to a single patient, even if it is a multidose vial. Proper aseptic technique should always be followed.

- When preparing more than one injection, always label the syringe immediately. Keep the medication container with the syringe. Do not rely on your memory to recall which solution is in which syringe.
- Never administer a medicine that is unlabeled and that was prepared by someone else. In doing so, you accept the responsibility for accuracy, dose, and correct medication.
- Never administer a medication that is outdated. Likewise, never give one that looks discolored, cloudy, or in any other way unusual, or as if someone has tampered with it.
- If the patient or your co-workers express doubt or concern about a medication or dose, recheck it. Do not administer it until you are sure no error has been made. Remember that the patient has the right to refuse a medication.
- Carefully monitor the patient for any adverse effects. Monitor for at least 5 minutes after you give the medication. (Intramuscular and oral medicines may require longer monitoring.)
- Document all medications given. This includes the name of the drug, the dosage, and the time and route of administration. When documenting parenteral medications, note the site of injection. The patient's response, adverse as well as intended, also is recorded.
- Follow government guidelines and local emergency medical services (EMS) policies regarding the return and disposal of any unused medication.

CRITICAL THINKING
Your clinical preceptor hands you an unlabeled syringe of medication and tells you to give it by intramuscular injection. What do you do?

Medication Errors

Medication errors *(adverse drug events)* occur with some frequency. An estimated 1.5 million people (hospital patients and nursing home residents) receive the wrong medicine or the incorrect dose of medicine in the United States each year. Of these, about 7000 people die annually.[3] Common causes of medication errors include the following:

- The prescriber ordered the wrong dose of medication.
- Drug calculations were incorrect.
- Drugs were administered by the wrong route.
- The drug was given to the wrong patient.
- The wrong drug was given to the patient.

If a medication error occurs, paramedics should do the following:

- Accept responsibility for the error.
- Immediately advise medical direction or the prescriber.
- Assess and monitor the patient for effects of the drug.
- Document the error as required by local and state drug administration policies and those of the medical direction institution.
- Modify personal practice to avoid a similar error in the future.

- Follow EMS agency procedures for documentation and quality improvement activities.

NOTE

Most injectable medications are given as their mass concentration (mg/mL or mcg/mL). For only a few drugs (e.g., epinephrine) is the concentration expressed as a ratio or percentage. These expressions are error prone because (1) practitioners may not recognize or understand the difference between dose concentrations (e.g., 1:1000 or 1 mg/mL and 1:10,000 or 0.1 mg/mL); and (2) numbers in the thousands are easily confused, because they have so many zeros (e.g., at a quick glance, 1,000 may be mistaken for 10,000). Paramedics should be especially careful when administering epinephrine. They should always have a co-worker double-check the dose and route of administration. This can help prevent a life-threatening drug error.

LOOK AGAIN

See Chapter 4: Documentation, pp. 71-72.

SHOW ME THE EVIDENCE

Vilke and colleagues surveyed paramedics in San Diego County to determine their experience with drug errors. According to the 352 surveys returned, 9.1% of paramedics reported committing a drug error within the last 12 months. Most of the errors reported were dose related (63%). Other errors were related to: protocol (33%); wrong route (21%); and wrong medication (4%). Of the errors noted in the survey, 4.2% had been noted during the call but had not been previously reported by the paramedic. The authors noted the need for additional safeguards to reduce the incidence of medication errors.

From Vilke G et al: Paramedic self-reported medication errors, *Prehosp Emerg Care* 10:457-462, 2006.

MEDICAL ASEPSIS

Medical asepsis is the removal or destruction of disease-causing organisms or infected material. Medical asepsis is performed by using "clean" technique (rather than sterile technique). *Clean technique* includes hygienic measures, cleaning agents, antiseptics, disinfectants, and barrier fields.

NOTE

Sterile technique means using sterile equipment and sterile fields that are free of all forms and types of life. This is also known as *surgical asepsis*. *Clean technique* focuses on destroying or inhibiting only pathogens (not all forms and types of life).

Antiseptics and Disinfectants

Antiseptics and disinfectants are chemical agents. They are used to kill specific groups of microorganisms. They generally are not very effective against spores of bacteria and fungi, many viruses, and some resistant bacterial strains. Disinfectants are used only on nonliving objects and are toxic to living tissue. Antiseptics are applied only to living tissue and are more dilute, to prevent cell damage. Some chemical agents have both antiseptic and disinfectant properties. Examples of these are alcohol and some chlorine compounds (Box 14-5 and Table 14-2).

NOTE

New disinfection methods are under consideration by the Environmental Protection Agency (EPA) and the Food and Drug Administration (FDA). These include a persistent antimicrobial drug coating that can be applied to inanimate and animate objects (Surfacine); a high-level disinfectant with reduced exposure time (orthophthalaldehyde); and an antimicrobial drug that can be applied to animate and inanimate objects (superoxidized water).[4]

UNIVERSAL PRECAUTIONS IN MEDICATION ADMINISTRATION

As described in Chapter 2, **universal precautions** are infection control practices in health care that are observed with every patient and procedure and that prevent exposure to blood-borne pathogens. (Personal protective measures are described in the appendix for this chapter and in Chapter 28.) When administering drugs, paramedics should follow hand washing procedures. They also should follow gloving procedures if indicated. Face shields should be used during administration of endotracheal drugs and whenever splashing of blood or body fluids is likely.

NOTE

Many consider hand washing the most crucial step in reducing the risk of transmission of organisms from one person to another or from one site to another on the same patient.[4] Hand washing protects both the paramedic and the patient. If soap and water are not available, a sanitizing gel, foam, or wipe should be used.

BOX 14-5 Examples of Antiseptics and Disinfectants

Antiseptics	Disinfectants
• Hexachlorophene	• Cresol
• Silver nitrate	• Carbolic acid
• Benzoyl peroxide	• Lysol

TABLE 14-2 Sterilization and Disinfection Methods for Equipment Used by Paramedics*

Organisms Destroyed	Methods	Uses
Sterilization		
All forms of microbial life, including high numbers of bacterial spores	Steam under pressure (autoclave), gas (ethylene oxide), dry heat, or immersion in an Environmental Protection Agency (EPA)-approved chemical sterilant for a prolonged period (e.g., 6 to 10 hours or according to the manufacturer's instructions). *Note*: Liquid chemical sterilants should be used only on instruments that cannot be sterilized or disinfected with heat.	Instruments or devices that penetrate the skin or come into contact with normally sterile areas of the body (e.g., scalpels, needles). Use of disposable invasive equipment eliminates the need to reprocess these items. When indicated, however, arrangements should be made with a health care facility for reprocessing of reusable invasive instruments.
High-Level Disinfection		
All forms of microbial life except high numbers of bacterial spores	Hot water pasteurization (176° to 212° F [80° to 100° C] for 30 minutes), or exposure to an EPA-registered chemical sterilant, except for a short exposure time (10 to 45 minutes or as directed by the manufacturer).	Reusable instruments or devices that come into contact with mucous membranes (e.g., laryngoscope blades, endotracheal tubes).
Intermediate-Level Disinfection		
Mycobacterium tuberculosis, vegetative bacteria, most viruses, and most fungi but not bacterial spores	EPA-registered hospital disinfectant chemical germicides with a label claim of tuberculocidal activity; commercially available hard surface germicides; or solutions with at least 500 parts per million (ppm) free available chlorine (a 1:100 dilution of common household bleach—approximately 1 cup of bleach per 1 gallon of tap water).	Instruments and equipment that come into contact only with intact skin (e.g., stethoscopes, blood pressure cuffs, splints) and that have been visibly contaminated with blood or bloody body fluids. Surfaces must be cleaned of visible material before the germicide is applied.
Low-Level Disinfection		
Most bacteria, some viruses, some fungi, but not *Mycobacterium tuberculosis* or bacterial spores	EPA-registered hospital disinfectants (no label claim for tuberculocidal activity).	Routine housekeeping or removal of soiling in the absence of visible blood contamination.
Environmental Disinfection	Any cleaner or disinfectant agent intended for environmental use.	Environmental surfaces that have become soiled and that should be cleaned and disinfected (e.g., floors, woodwork, ambulance seats, countertops).

*To ensure the effectiveness of any sterilization or disinfection process, equipment and instruments first must be thoroughly cleaned of all visible soiling.

ENTERAL ADMINISTRATION OF MEDICATIONS

Enteral medications are drugs that are administered and absorbed through the gastrointestinal tract. Enteral drugs are administered by the oral, gastric, or rectal route.

LOOK AGAIN

See Chapter 13: Principles of Pharmacology and Emergency Medications, pp. 283-286.

Oral Route

The oral route is the most frequently used method of drug administration. The patient should be in an upright or sitting position. The pill, tablet, or capsule should be placed in the patient's mouth and swallowed with enough fluid (4 to 8 ounces) to make sure the drug reaches the stomach. Some oral drugs, such as ***ondansetron,*** are placed on the tongue and allowed to dissolve without water. Medication should not be administered orally if the patient cannot swallow or does not have an effective gag reflex.

BOX 14-6 Forms of Solid and Liquid Oral Medications

- Caplets
- Capsules
- Time-released capsules
- Lozenges
- Pills
- Tablets
- Elixirs
- Emulsions
- Suspensions
- Syrups

CRITICAL THINKING

Think of some clinical situations in which oral administration of a drug would not be the best technique. Why is this so?

Many oral drugs are manufactured in solid and liquid forms (Box 14-6). If the medication is in a liquid suspension, the stock bottle or unit dose should be shaken thoroughly before the drug is poured for administration. A drug not packaged as a unit dose should be measured in a medicine cup or a medicine dropper or by syringe.

Administration of Medications by Gastric Tube

Most drugs that can be given orally can also be given via a gastric tube. Orogastric tubes are placed through the mouth and into the esophagus and stomach. Nasogastric tubes are placed through the nose and esophagus and into the stomach. Before giving a drug by this route, the paramedic must make sure the tube has been inserted correctly (see Chapter 29). This can be done by injecting 30 to 50 mL of air into the tube and auscultating the epigastric region for the sound of air movement. Once correct insertion has been verified, the drug is administered through the tube, followed by a small amount of water (about 30 mL). The water flushes the drug and helps to maintain the patency of the tube. An emergency drug that is given by gastric tube is ***activated charcoal.***

NOTE

The traditional method of auscultating the epigastric area to confirm correct tube placement may not always be reliable.[5] Other ways to confirm correct placement include asking the patient to speak (if the tube is in the trachea, the patient will be unable to talk); visually inspecting the posterior pharynx for the presence of a coiled tube; aspirating gently on the syringe to obtain gastric fluid; and measuring the pH of the aspirate.[6] These methods require special training. The paramedic should follow protocols approved by medical direction.

BOX 14-7 Procedure for Administering Rectal Drugs*

1. Carefully restrain the child. If possible, place the child in a knee-chest or lateral recumbent position with the legs flexed at the hips and the knees.
2. Draw the drug dose into a syringe and remove the needle. (A slightly higher dose may be required because absorption is incomplete. Consult medical direction.)
3. Insert the lubricated syringe just beyond the external sphincter (aiming just above the junction of the skin and mucous membranes and toward the rectal wall).
4. Inject the solution into the rectum.
5. Aid drug retention by squeezing the buttocks together with manual pressure.

*Although the procedure is described for a child, it also is appropriate for adults.

Rectal Administration of Medications

Some drugs, such as suppositories, are made for rectal administration (Box 14-7). Other drugs can be given by the rectal route when vascular access cannot be established. Emergency drugs that can be given rectally include ***diazepam*** and ***lorazepam*** (Figure 14-7).

PARENTERAL ADMINISTRATION OF MEDICATIONS

Parenteral drugs are administered outside the gastrointestinal tract. This term usually refers to injections. Drugs are administered parenterally by the intradermal, subcutaneous, intramuscular, intravenous, and intraosseous routes. (Percutaneous medications also are discussed in this section.) Blood collection procedures (phlebotomy procedures) are discussed later in this chapter.

NOTE

Parenteral administration of drugs can be very hazardous. This is because drugs given by injection are usually thought to be irretrievable. Also, a slight risk of infection exists, because the skin is broken. Other possible hazards associated with parenteral administration include pain with drug administration, cellulitis or abscess formation, necrosis, skin sloughing, nerve injury, prolonged pain, and periostitis (inflammation of connective tissue covering bones). The use of aseptic technique, ensuring an accurate drug dosage, finding the proper site for the injection, and administering the injection at the proper rate are essential to minimizing the risk of harm.

Equipment Used for Injections

SYRINGES AND NEEDLES

The choice of syringe and needle depends on three factors: (1) the route of administration, (2) the characteristics of the fluid (e.g., aqueous or oil based), and (3) the volume of

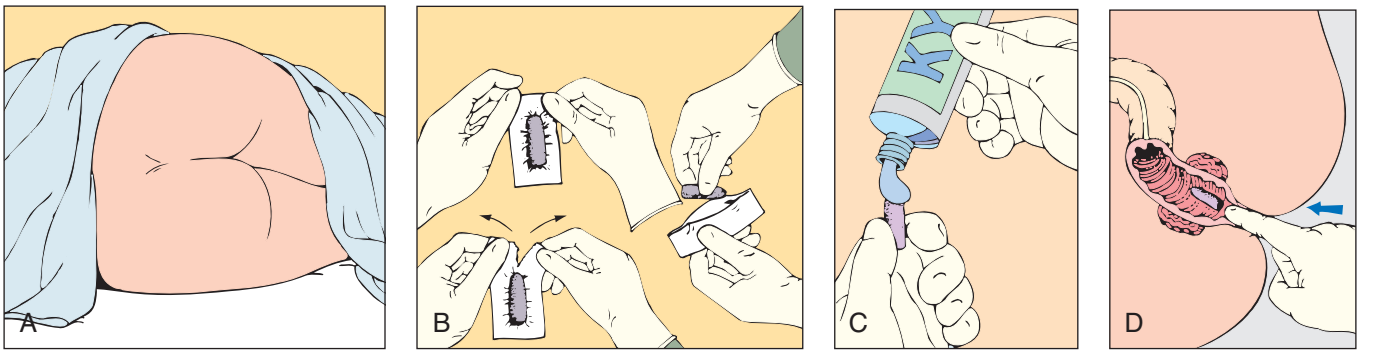

FIGURE 14-7 Rectal drug administration. **A,** Position the patient in the lateral recumbent position and drape. **B,** Unwrap the suppository and remove it from the package. **C,** Apply a water-soluble lubricant. **D,** Gently insert the suppository about 1 inch past the internal sphincter. (Clayton BD, Stock YN, Harroun RD: *Basic pharmacology for nurses,* ed 14, St Louis, 2007, Mosby.)

medication. Syringes in common use today are made of disposable plastic. Sizes range from 1 mL tuberculin and insulin syringes to 60 mL irrigation syringes.

Tuberculin syringes are marked in 0.01 mL gradients. They should be used when the volume to be given is small. Insulin syringes are available in 0.5 and 1 mL volumes. They are marked in 1-unit increments. When used with the specified strength of insulin, this syringe allows the patient to draw up the correct dose easily without doing any calculations. Tuberculin and insulin syringes should not be substituted for each other. Figure 14-8 shows syringes used to measure varying amounts of liquids and liquid medications accurately.

Needles vary in length and gauge. Length ranges from ⅜ inch to 3 inches or longer. Gauge ranges from 12 gauge (large lumen) to 30 gauge (small lumen). Smaller lumen (larger gauge) needles usually are used for intradermal injections. Subcutaneous injections usually are given with a ⅝-inch, 23- or 25-gauge needle. Intramuscular injections usually are given with a 1- to 2-inch, 19- or 21-gauge needle; occasionally a 16- or 18-gauge needle is used.

In 2000 Congress passed the Healthcare Worker Needlestick Prevention Act. The following year, the Occupational Safety and Health Administration (OSHA) amended its Bloodborne Pathogens Standard to recommend needleless systems or "needle safe" devices (sharps with engineered sharps protection). These devices collect body fluids or deliver medications without the use of a needle, which helps prevent blood exposure and needlestick injuries (Box 14-8). Examples of these devices include self-sheathing hypodermic syringes, retractable needles for injections, self-blunting phlebotomy needles, retracting lancets, filter straws, vial access cannulas, and disposable retracting scalpels.

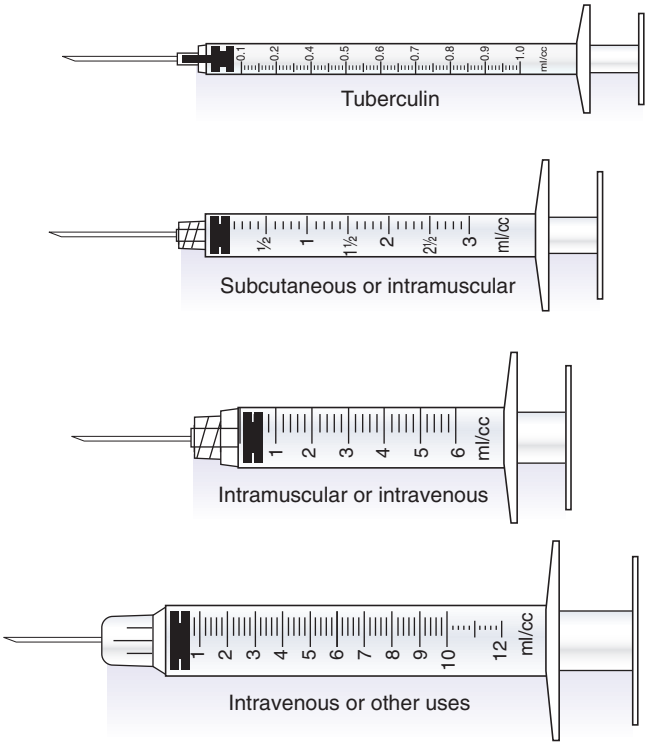

FIGURE 14-8 Types of syringes.

CONTAINERS USED FOR PARENTERAL MEDICATIONS

Medications given by injection usually are supplied in three forms. They come in *single-dose ampules, multidose vials,* or *prefilled syringes.* Single-dose ampules are glass containers that hold one dose of a medication for injection. After use, the ampule is discarded into a sharps container. Multidose vials are glass containers that come with rubber stoppers. These permit several medication doses to be withdrawn for injection. In general, these are intended for single-patient use.

To prepare a prescribed medication for injection, the paramedic should choose the appropriate needle and syringe. The size of the syringe must be in proportion to the volume of solution to be given. To withdraw medication from an ampule or vial, the paramedic should follow these steps:

1. Assemble the equipment (alcohol swab or gauze, syringe, 18-gauge filter needle or filter straw to withdraw

medication if using an ampule, and appropriate-gauge needle for injection).
2. Compute the volume of medication to be given.
3. If using a vial (Figure 14-9):
   (a) Clean the rubber stopper with alcohol.
   (b) Inject a volume of air into the vial equivalent to the amount of solution to be withdrawn. (This prevents the formation of a vacuum in the vial. A vacuum can make the solution difficult to withdraw.) Withdraw the volume required and remove the syringe from the vial.
   (c) Gently push in the plunger of the syringe to expel air from the solution.
4. If using an ampule (Figure 14-10):
   (a) Lightly tap or shake the ampule to dislodge any solution from the neck of the container.
   (b) Wrap the neck of the glass ampule with an alcohol swab or gauze dressing to protect the fingers.
   (c) Grasp the ampule, snap off the top, and discard the top in an appropriate medication disposal container. (The ampule is designed to break easily when pressure is exerted at the neck.)
   (d) Carefully insert an 18-gauge filter needle or filter straw into the solution, without allowing it to touch the edges of the ampule, and draw the solution into the syringe.
   (e) Carefully remove the 18-gauge needle or filter screw and discard it in the appropriate container. Attach the needle to be used for injection.
   (f) Gently push in the plunger of the syringe to expel air.

Mixing Medications. Two compatible drugs can be mixed into one injection if the total volume of the dosage is within accepted limits. For example, this technique can be used with ***butorphanol*** and ***hydroxyzine.*** When mixing medications, it is crucial not to contaminate one with the other and to maintain aseptic technique. Any doubt about compatibility should be discussed with medical direction. It also can be verified by consulting a proper reference, such as a drug compatibility chart. To mix medications, the paramedic should take the following steps.

BOX 14-8 Prevention of Needle and Sharps Injuries

Each year, health care workers suffer 600,000 to 1 million injuries from conventional needles and sharps.[15] Infection with the hepatitis C virus (HCV) is the most common infection caused by needle-stick and sharps injury.[16] However, transmission of other diseases also is possible. These diseases include human immunodeficiency virus (HIV) infection, hepatitis B, syphilis, herpes simplex, herpes zoster, Rocky Mountain spotted fever, and tuberculosis. The following precautions can help prevent exposure to these pathogens.

- Paramedics should get help when administering infusion therapy or injections to uncooperative patients.
- Needles should not be recapped, purposely bent or broken by hand, removed from disposable syringes, or otherwise manipulated by hand. If a needle must be recapped or removed because there is no alternative or because a specific medical procedure requires it, the paramedic should use a mechanical device or a one-handed technique. Needleless products should be used when available.
- Disposable syringes and needles, scalpel blades, and other sharp items should be placed in puncture-resistant containers for disposal.

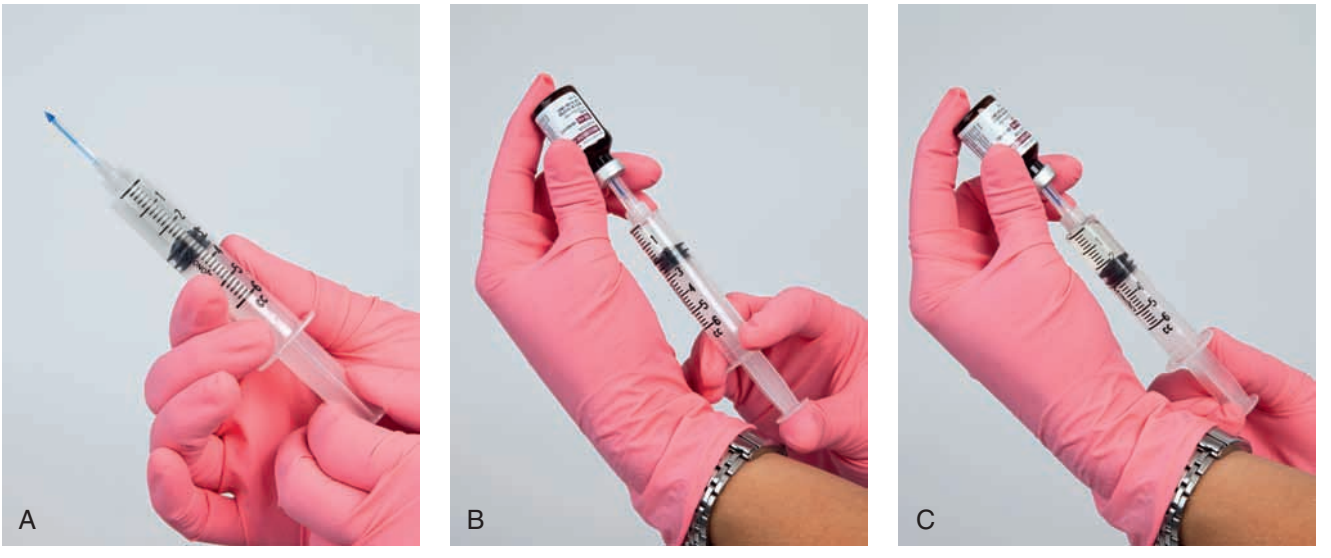

FIGURE 14-9 Withdrawing medication from a vial. **A,** Draw into the syringe an amount of air equal to the volume to be given. **B,** Inject air into the drug vial. **C,** Draw the drug into the syringe.

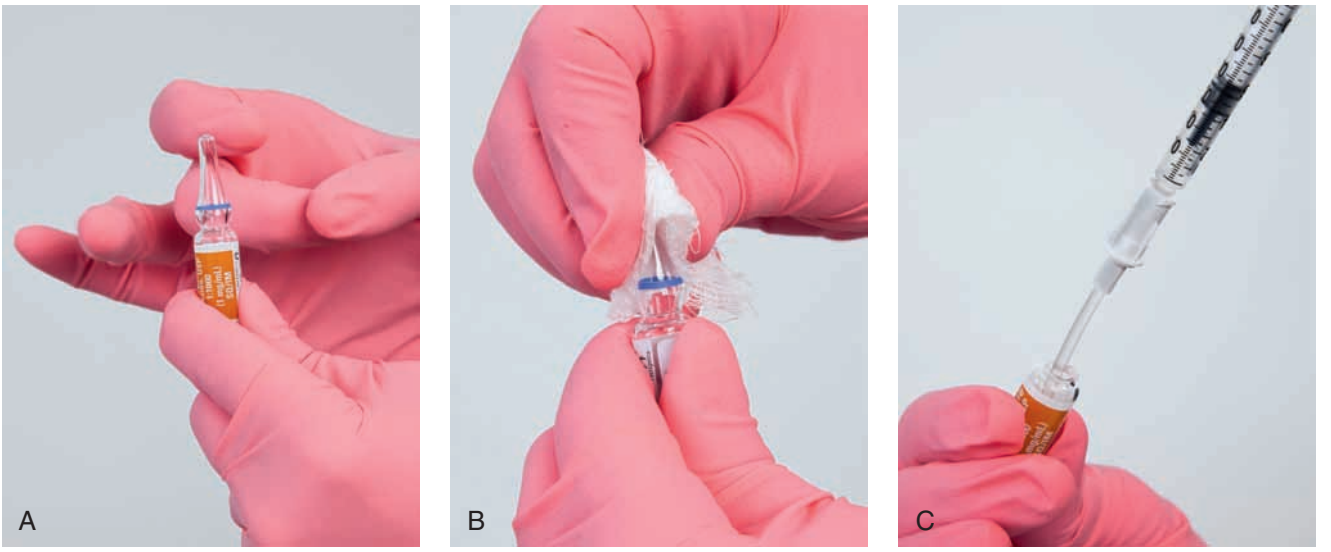

FIGURE 14-10 Withdrawing medication from an ampule. **A**, Tap the ampule to remove drug from the neck. **B**, Break off the top of the ampule with a gauze pad. **C**, Use a filter straw to withdraw the medication from the ampule.

Mixing Medications from Two Vials

1. Use only one syringe to mix the drugs.
2. Aspirate a volume of air equivalent to the dose of the first drug. Inject the air into vial A, making sure the needle or vial access cannula does not touch the solution. Withdraw the needle or vial access cannula.
3. Aspirate a volume of air equivalent to the dose of the second drug. Inject the air into vial B. Withdraw the required medication from vial B.
4. Put a new sterile needle or vial access cannula on the syringe and insert it into vial A. Be careful not to push in the plunger or expel the drug from the syringe into the vial. This would pose a risk of infection and result in mixing of the drugs.
5. Withdraw the desired amount of the drug from vial A into the syringe.
6. Put a new sterile needle on the syringe and administer the injection.

NOTE

Some medications are dry powders that must be reconstituted before administration. An example is glucagon. Carefully read the manufacturer's information. Use the correct amount of the diluent prescribed for this purpose. Always mix the diluent and powder in the closed vial before withdrawing the dose. Some drugs are packaged in a vial that contains the diluent and powder in two compartments (Mix-o-Vial).

Mixing Medications from One Vial and One Ampule

1. Withdraw the desired drug dose from the vial first.
2. Use the same syringe and needle or filter straw to withdraw medication from the ampule.
3. Put a new sterile needle on the syringe (if the medication is to be given by the intramuscular or subcutaneous route) and administer the injection.

FIGURE 14-11 Prefilled medication syringe.

Prefilled Syringes. Several manufacturers make prefilled syringes (Figure 14-11). The techniques for activating and using the products vary. Paramedics should be familiar with the devices used by particular EMS systems. The technique for activating a common type of prefilled syringe is as follows:

1. Calculate the volume of medication to be administered.
2. Remove the protective caps from the syringe barrel and medication cartridge.
3. Screw the cartridge into the syringe barrel.
4. Gently push in the plunger of the syringe to expel air.

PREPARING THE INJECTION SITE

The injection site is prepared by cleansing the area using aseptic technique. The Guidelines for Prevention of Intravascular Catheter-Related Infections, published by the

Centers for Disease Control and Prevention (CDC), state that "although 2% chlorhexidine-based preparation is preferred, tincture of iodine, an iodophor, or 70% alcohol can be used."[7]

The steps in preparing the injection site are as follows:

1. Thoroughly scrub the site with the appropriate cleanser to remove dirt, dead skin, and other surface contaminants.
2. If using a chlorhexidine-based preparation, scrub the area up and down and then side to side. If using other products, clean the site with overlapping, concentric circles and moving outward from the site.
3. Allow the site to dry.

Intradermal Injections

An intradermal injection is made just below the *epidermis,* or outer layer of skin (Figures 14-12 and 14-13). This site is commonly used for allergy testing and for administration of local anesthetics. A tuberculin syringe usually is used for intradermal injections. The volume injected usually is less than 0.5 mL. Common sites for intradermal injections are the medial surface of the forearm and the back. The steps for administering an intradermal injection are as follows:

1. Choose the injection site and cleanse the skin surface.
2. Hold the skin taut with one hand.
3. With the other hand, hold the syringe (with the needle bevel up) at a 10- to 15-degree angle to the injection site.
4. Gently puncture the skin. Insert the needle until the bevel is completely under the skin surface. Inject the medication. (Intradermal injections usually produce a raised wheal that resembles a mosquito bite.)
5. Withdraw the needle and dispose of the equipment appropriately.

Subcutaneous Injections

Subcutaneous injections are given to place medication below the skin into the subcutaneous layer (Figure 14-14). The volume of such an injection usually is less than 0.5 mL. It is administered through a ½- or ⅝-inch, 23- or 25-gauge needle. In the prehospital setting, the drug most often given by this route is ***epinephrine.*** The steps for subcutaneous injections are as follows (Figure 14-15):

1. Choose the injection site and cleanse the area.
2. Elevate the subcutaneous tissue by gently pinching the injection site.

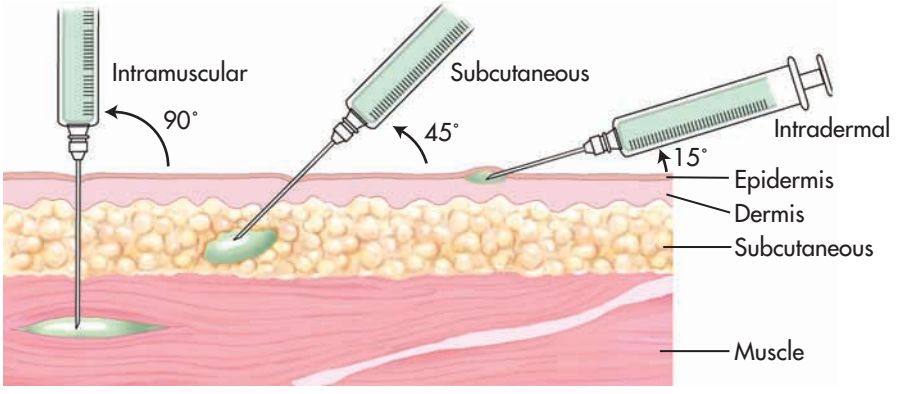

FIGURE 14-12 Comparison of angle of injection and deposition of medication for intramuscular, subcutaneous, and intradermal injections.

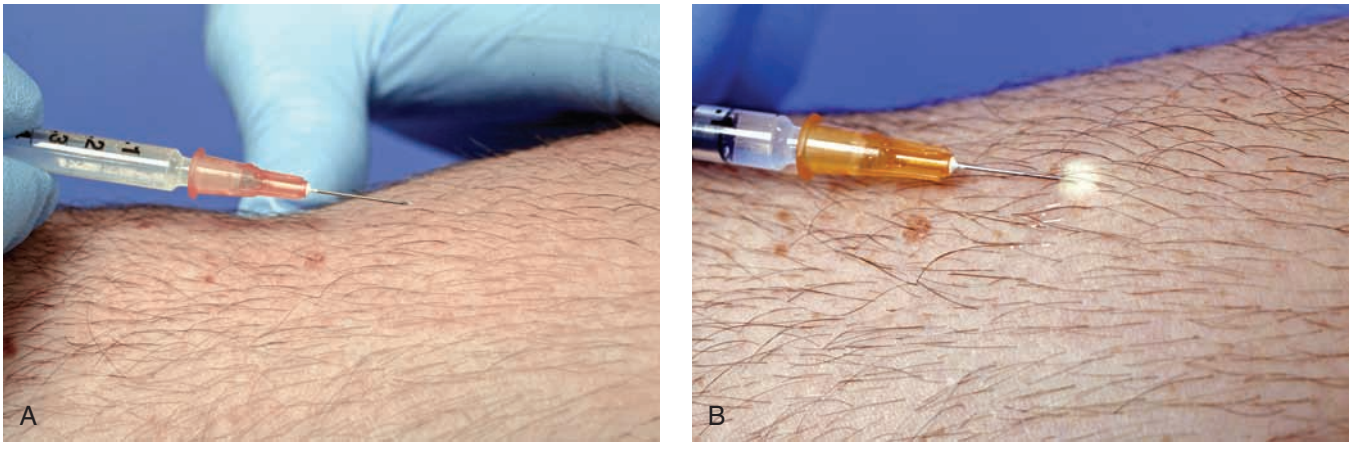

FIGURE 14-13 Intradermal injection. Choose the site and cleanse the skin. **A,** Then, with the bevel up, insert the needle at a 15-degree angle. **B,** Wheal produced by the injection.

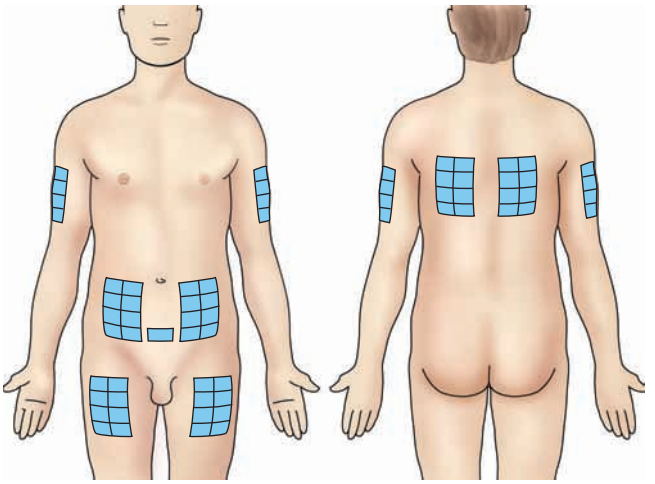

FIGURE 14-14 Sites commonly used for subcutaneous injections.

3. With the needle bevel up, insert the needle at a 45-degree angle in one quick motion.
4. Pull back slightly on the plunger (aspirate) to ensure needle placement. If no blood is aspirated, gently but smoothly inject the medication. If blood is present on aspiration, it indicates inadvertant vascular injection. When this occurs, withdraw the needle, discard the medication and equipment, and begin again.
5. After the injection, withdraw the needle at the same angle at which it was inserted. Use an alcohol swab to massage the site. This helps distribute medication and promote absorption by dilating blood vessels in the area and increasing blood flow.

FIGURE 14-15 Subcutaneous injection. **A**, Cleanse the skin. **B**, Grasp the skin to maximize the amount of subcutaneous tissue available and insert the needle. Aspirate unless contraindicated. **C**, Slowly push the plunger to administer the medication. **D**, Discard the needle and syringe in an appropriate sharps container.

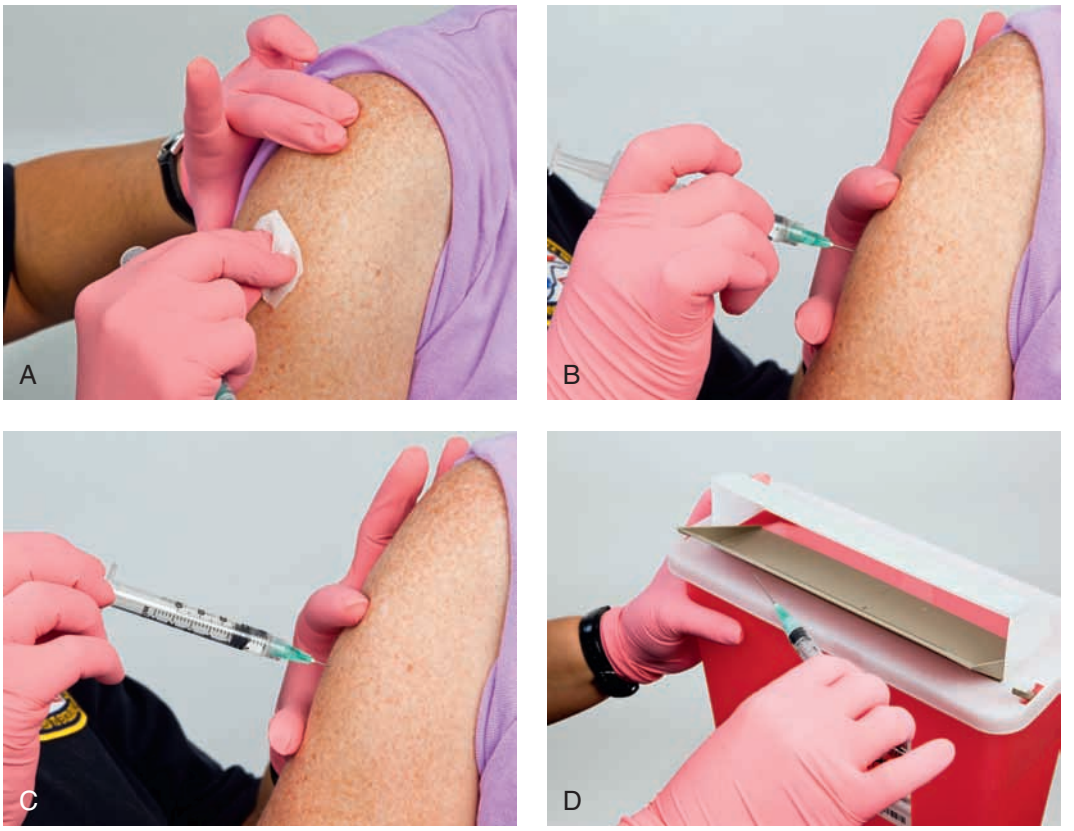

FIGURE 14-16 Intramuscular injection. **A**, Choose the site and cleanse the skin. **B**, Pull the skin tight and insert the needle. **C**, Aspirate and then slowly push the plunger to inject the medication. **D**, Discard the needle and syringe in an appropriate sharps container.

Intramuscular Injections

Deeper injections are made into muscle tissue. These pass through the skin and subcutaneous tissue. They are given when a drug is too irritating to be injected subcutaneously or when a greater volume or faster absorption is desired. (Irritation still may occur with administration by this route.) A maximum volume of 5 mL may be given by intramuscular injection in a large muscle mass (e.g., gluteal muscle).

The type of needle used depends on four factors: (1) the site of the injection; (2) the condition of the tissue; (3) the size of the patient; and (4) the type of drug to be injected (i.e., small-lumen needles are used for thin solutions, and larger lumen needles are used for suspensions and oils). Because the muscle layer is below the subcutaneous layer, a longer needle generally is used (usually 1½ inches and 19 or 21 gauge). The procedures for intramuscular injections are the same as those described before (Figure 14-16). However, the needle is inserted at a 90-degree angle. Also, the skin is held taut, not pinched.

Several muscles are commonly used for intramuscular injections. These are the deltoid muscle, several gluteal muscles (dorsogluteal site), the vastus lateralis muscle, the rectus femoris muscle, and the ventrogluteal muscle. The deltoid muscle is located in the upper arm. It forms a triangular shape, with the base of the triangle along the acromion process and the peak of the triangle ending approximately one third of the way down the lateral aspect of the upper arm (Figure 14-17). This muscle is used primarily for vaccinations involving only a small volume of

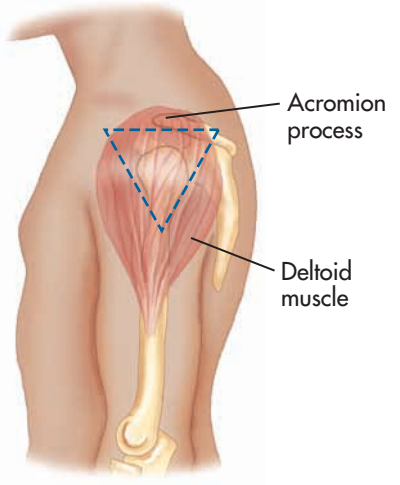

FIGURE 14-17 The injection site for the deltoid muscle roughly forms an inverted triangle, with the acromion process as the base. The muscle may be visible in well-developed patients.

drug. This is because the muscle is small and can accommodate only small doses of injection (1 mL or less). When injections are made in this location, care must be taken to avoid hitting the radial nerve. The patient should be sitting upright or lying flat and should be told to relax the arm muscles.

The dorsogluteal site consists of several gluteal muscles. The gluteus medius muscle is most often used for injections. The dorsogluteal site can be defined in two ways. The first method is to divide the buttocks on one side into imaginary quadrants; the medication is administered into the upper outer quadrant. The second method is to locate the posterior-superior iliac spine and the greater trochanter of the femur. An imaginary line is drawn between the two landmarks; the injection is given up and out from this line (Figure 14-18). This site should not be used for children under 3 years of age. In that age group, the muscles are not yet well developed and the proximity of the sciatic nerve (the largest nerve in the body) poses a risk. Large, well-developed muscles can accommodate an injection of up to 5 mL. However, volumes over 3 mL may be uncomfortable for the patient. When an injection is administered at the dorsogluteal site, the patient should be lying prone. The toes should be pointing inward to promote muscle relaxation. Another complication of gluteal injections is inadvertent injection into the hip joint. The paramedic can minimize this risk by paying attention to anatomical landmarks.

The vastus lateralis and the rectus femoris muscles lie side by side in the thigh. To identify the necessary landmarks, the paramedic should place one hand on the patient's upper thigh and one hand on the lower thigh. The area between the hands is the middle third of the thigh and the middle third of the underlying muscle (Figure 14-19). The vastus lateralis lies lateral to the midline and is the preferred injection site for children. It is well developed in all patients and has few major blood vessels and nerves that can be injured. The rectus femoris is located in the midline of the middle third of the thigh. This site is most often used for self-injection because of its accessibility. Acceptable volumes for injection vary with the age of the patient and the size of the muscle. Up to 5 mL may be injected into a well-developed adult. The patient should be sitting upright or lying supine and should be advised to relax the muscles.

The ventrogluteal muscle is accessible when the patient lies in a supine or lateral recumbent position. The paramedic should palpate the greater trochanter using the palm, with the index finger pointing to the anterior-superior iliac spine. The paramedic's remaining three fingers should extend toward the iliac crest. The injection is made into the center of the V formed by the fingers (Figure 14-20). This injection site may be used for all patients. It is a desirable site because it has no large nerves or fat tissue. In the adult, this muscle may accommodate up to 5 mL of drug.

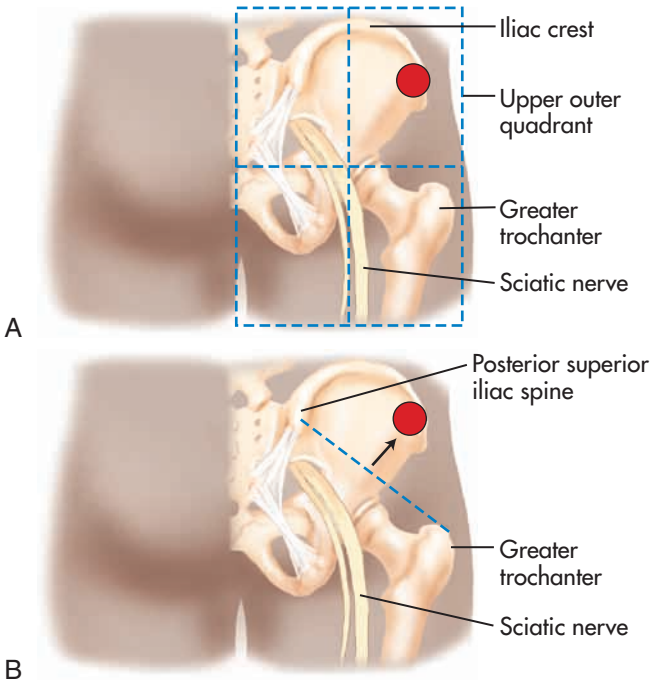

FIGURE 14-18 The injection area for the dorsogluteal site can be defined in two ways. **A,** Divide the buttocks on one side into imaginary quadrants. Use the center of the upper outer quadrant as the injection site. **B,** Locate the posterior-superior iliac spine and the greater trochanter by palpation. Draw an imaginary line between the two. The injection site should be above and out from that line.

NOTE
Some intramuscular medications (e.g., promethazine) should be administered into a large muscle. In such cases, use one of the leg or hip injection sites.

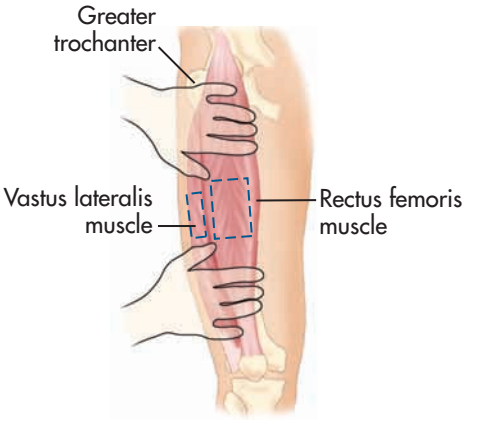

FIGURE 14-19 The injection sites for the vastus lateralis muscle and the rectus femoris muscle can be defined through landmarks. Place one hand below the greater trochanter. Place the other hand above the knee. The space between the two hands defines the middle third of the underlying muscle. The rectus femoris is on the anterior thigh. The vastus lateralis is on the lateral side.

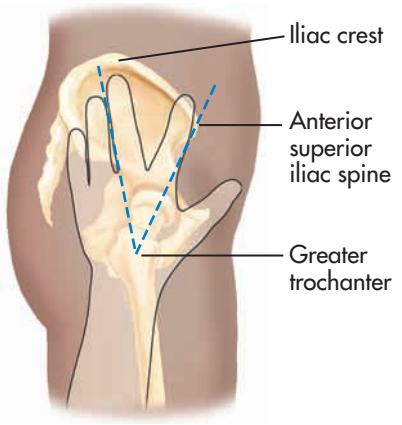

FIGURE 14-20 The injection site for the ventrogluteal muscle is defined by placing the palm of one hand on the trochanter of the femur. A V is then made with the fingers of that hand. One side runs from the greater trochanter to the anterior-superior iliac spine. The other side runs from the greater trochanter to the iliac crest. The injection is made into the center of the V.

FIGURE 14-21 Various types of intravenous (IV) catheters.

Intravenous Therapy

Intravenous cannulation is used to gain access to the body's circulation. It is indicated for three reasons: (1) to administer fluids; (2) to administer drugs; and (3) to obtain specimens for laboratory testing. The intravenous route puts the drug directly into the bloodstream. This bypasses all barriers to drug absorption.

CRITICAL THINKING
What are the benefits of choosing the upper extremity for intravenous access in an adult?

Intravenous Fluid Administration

In the prehospital setting, the route of choice for fluid therapy is through a peripheral vein in an extremity. If the arms have no major injury, upper extremity veins should be used. (Some EMS agencies advise against using upper extremity sites if a major injury to the neck or upper thorax has occurred on that side.) If upper extremity sites are not available, lower extremity sites may be used. IV fluids often used in the prehospital setting include normal saline, lactated Ringer solution, and mixtures of glucose and water. For the most part, normal saline and lactated Ringer solution are used for fluid replacement. They also are used as a means of administering a drug.

TYPES OF INTRAVENOUS CATHETERS

The three main types of intravenous catheters are (1) the hollow needle (butterfly) type; (2) the indwelling plastic catheter *over* a hollow needle (e.g., Protective Cath, Autoguard, Accuvance Safety) (Figure 14-21); and (3) the indwelling plastic catheter inserted *through* a hollow needle (e.g., Intracath; this type is seldom used in the prehospital setting).

Hollow needles are not advised for IV fluid replacement in the prehospital setting, because stabilizing the needle is very difficult. In some cases a butterfly catheter may be used for a pediatric patient if it can be stabilized adequately. This sometimes can be achieved by using armboards or other immobilization devices. In the prehospital setting, use of the over-the-needle catheter is preferred. This type of catheter is easily secured. Also, it is more comfortable for the patient.

PERIPHERAL INTRAVENOUS INSERTION

An area commonly used for peripheral intravenous therapy is the hands. Another is the arms. This includes the antecubital fossae (AC space). Other sites are the long saphenous veins in the leg and the external jugular veins in the neck. However, the incidences of embolism (described later) and infection are higher at the latter two sites. Figures 14-22 through 14-24 show sites and techniques for peripheral cannulation.

Another factor in the selection of a puncture site for intravenous therapy is the patient's clinical status. Injuries or diseases involving an extremity interfere with the use of veins in that extremity for venipuncture or venous cannulation. Examples of such conditions include trauma, infection at the site, dialysis fistula, and a history of mastectomy.

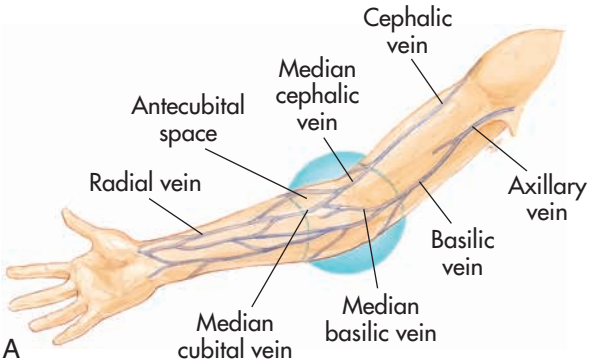
The following are the steps involved in peripheral venous insertion of a cannula.

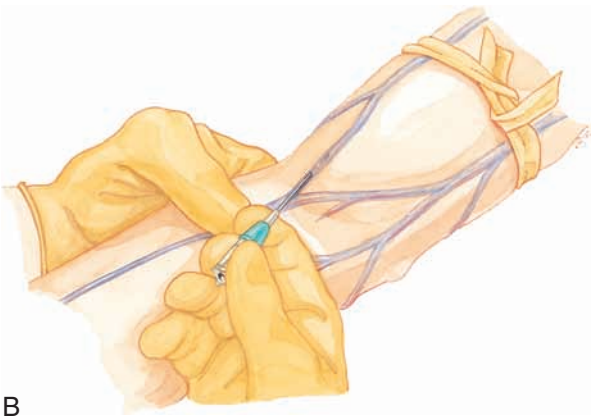
1. If the patient is conscious, explain the procedure. Give the reason intravenous therapy is necessary and describe the procedure.
2. Assemble the equipment (Figure 14-25).
   (a) Inspect the prescribed fluid for contamination, appearance, and expiration date. Never use fluids

that are cloudy, outdated, or in any way suspect for contamination.

(b) Prepare the microdrip or macrodrip infusion set. Attach the infusion set to the bag of solution. (Microdrip tubing usually is used for precise drug infusions; macrodrip tubing usually is used for fluid administration.)

3. Clamp the tubing and squeeze the reservoir on the infusion set until it fills halfway. Then open the clamp and flush the air from the tubing. Close the clamp.





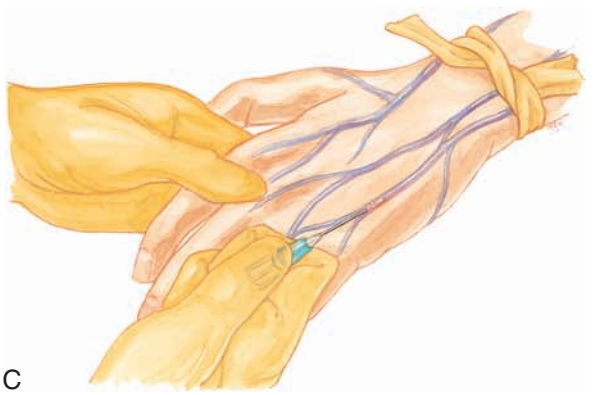


FIGURE 14-22 **A,** Veins of the upper extremity. **B,** Antecubital venipuncture. **C,** Dorsal hand venipuncture.

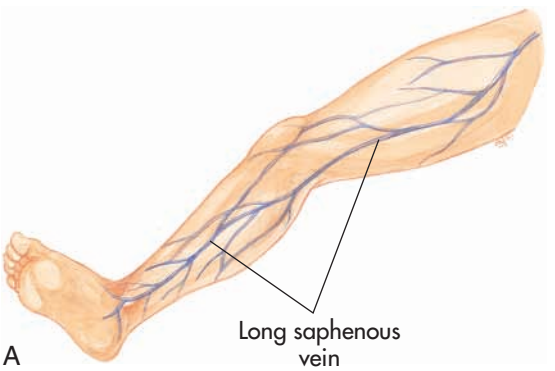

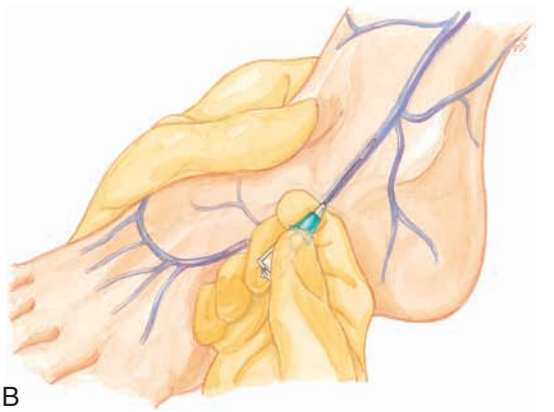

FIGURE 14-23 **A,** Long saphenous vein. **B,** Venipuncture of the long saphenous vein.

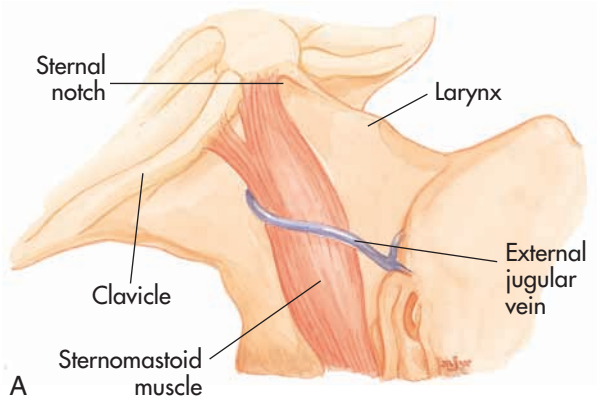

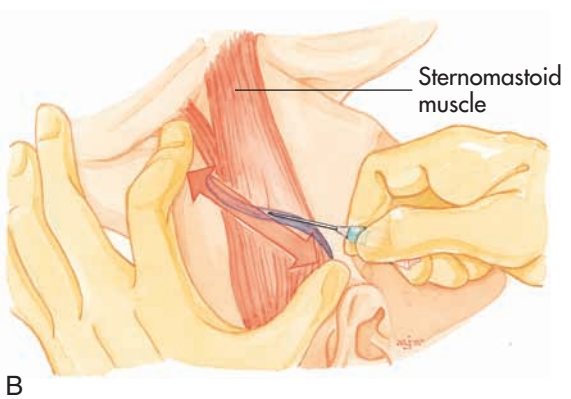

FIGURE 14-24 **A,** Anatomy of the external jugular vein. **B,** External jugular venipuncture.

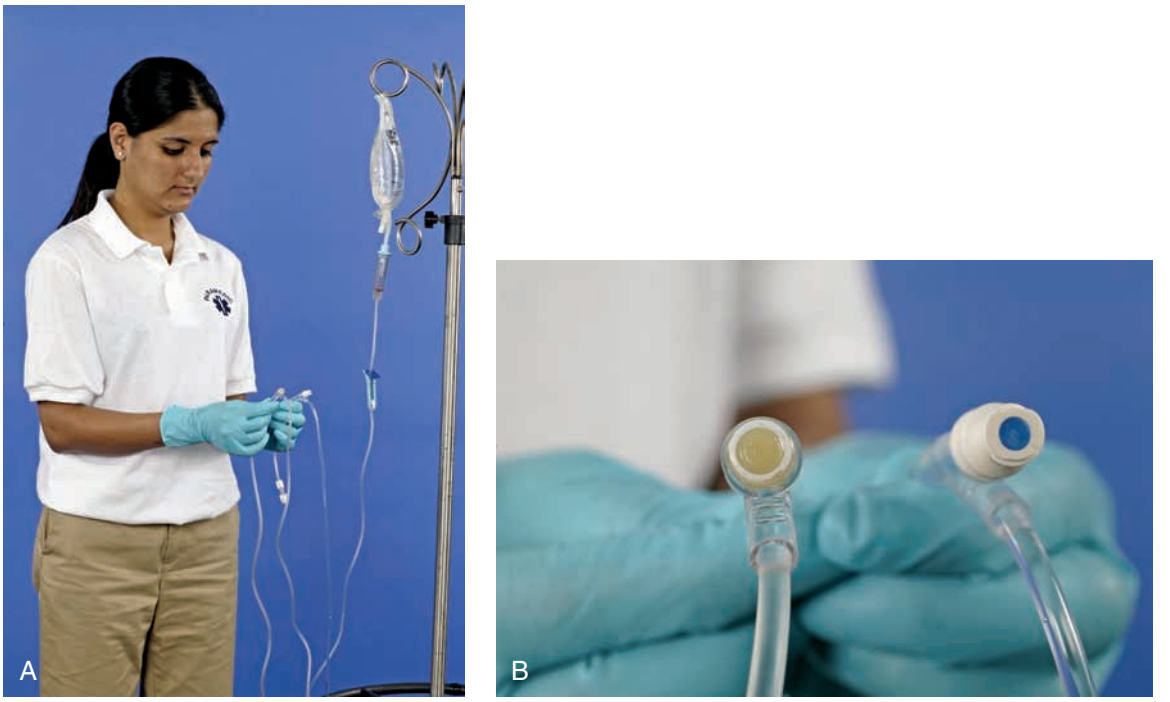

FIGURE 14-25 **A**, Intravenous infusion setup. **B**, Needle and needleless ports.

4. Select the catheter. A large-bore catheter (14 to 16 gauge) should be used for fluid replacement. A smaller bore catheter (18 to 20 gauge) should be used for "keep open" lines. Keep open lines are used to maintain hydration and to establish a channel for IV medication if needed.
5. Prepare other equipment:
   - Antiseptic to cleanse the skin
   - Sterile dressings or 4 × 4 gauze pads
   - Adhesive tape, torn or cut into several strips
   - Syringes and Vacutainers for blood samples
   - Tourniquet (rubber drain tubing or blood pressure cuff may be used)
6. Put on gloves for personal and patient protection.
7. Select the puncture site (Figure 14-26, *A*). If using an upper extremity, allow the patient's arm to hang dependent and apply the tourniquet several inches above the antecubital space. (The tourniquet should be just tight enough to tamponade venous vessels but not occlude arterial flow.) When selecting a suitable vein, begin by looking at the dorsum of the hand and forearm. Choose a vein that is fairly straight and easily accessible. The forearm is better than the hand because it allows hand movement and is more easily secured after cannulation. If a second puncture attempt is necessary, the second puncture should always be *proximal* to the first puncture. Therefore the vein selected for initial cannulation should be the most suitable distal vein. Avoid veins near joints, where immobilization is difficult, and veins near injured areas. If the long saphenous vein is chosen, begin site selection near the medial malleolus of the foot. To locate the external jugular vein, place the patient in a supine head-down position and turn the patient's head toward the opposite side.
8. Prepare the puncture site and cleanse the area (Figure 14-26, *B*):
   (a) Thoroughly clean the site with an antiseptic to remove dirt, dead skin, blood, and other surface contaminants. Allow the area to dry.
   (b) Clean the site using overlapping, concentric circles and moving outward.
9. Stabilize the vein by applying distal pressure and tension to the point of entry. With the bevel up, pass the needle through the skin and into the vein at a 15- to 20-degree angle from the side or directly on top (Figure 14-26, *C*). (Using a "bevel down" technique in infants and children may facilitate entry into constricted peripheral veins.[8]) Advance the needle and catheter about 2 mm beyond the point where blood return in the hub of the needle was first encountered. Slide the catheter over the needle and into the vein (Figure 14-26, *D*). (Avoid touching the catheter with the fingers.) While stabilizing the catheter, withdraw the needle. Apply pressure on the proximal end of the catheter to stop escaping blood. Obtain blood samples, if needed, with a syringe or Vacutainer.
10. Release the tourniquet and attach the IV tubing (Figure 14-26, *E*). Open the tubing clamp and allow the fluid infusion to begin at the prescribed flow rate (Figure 14-26, *F*).

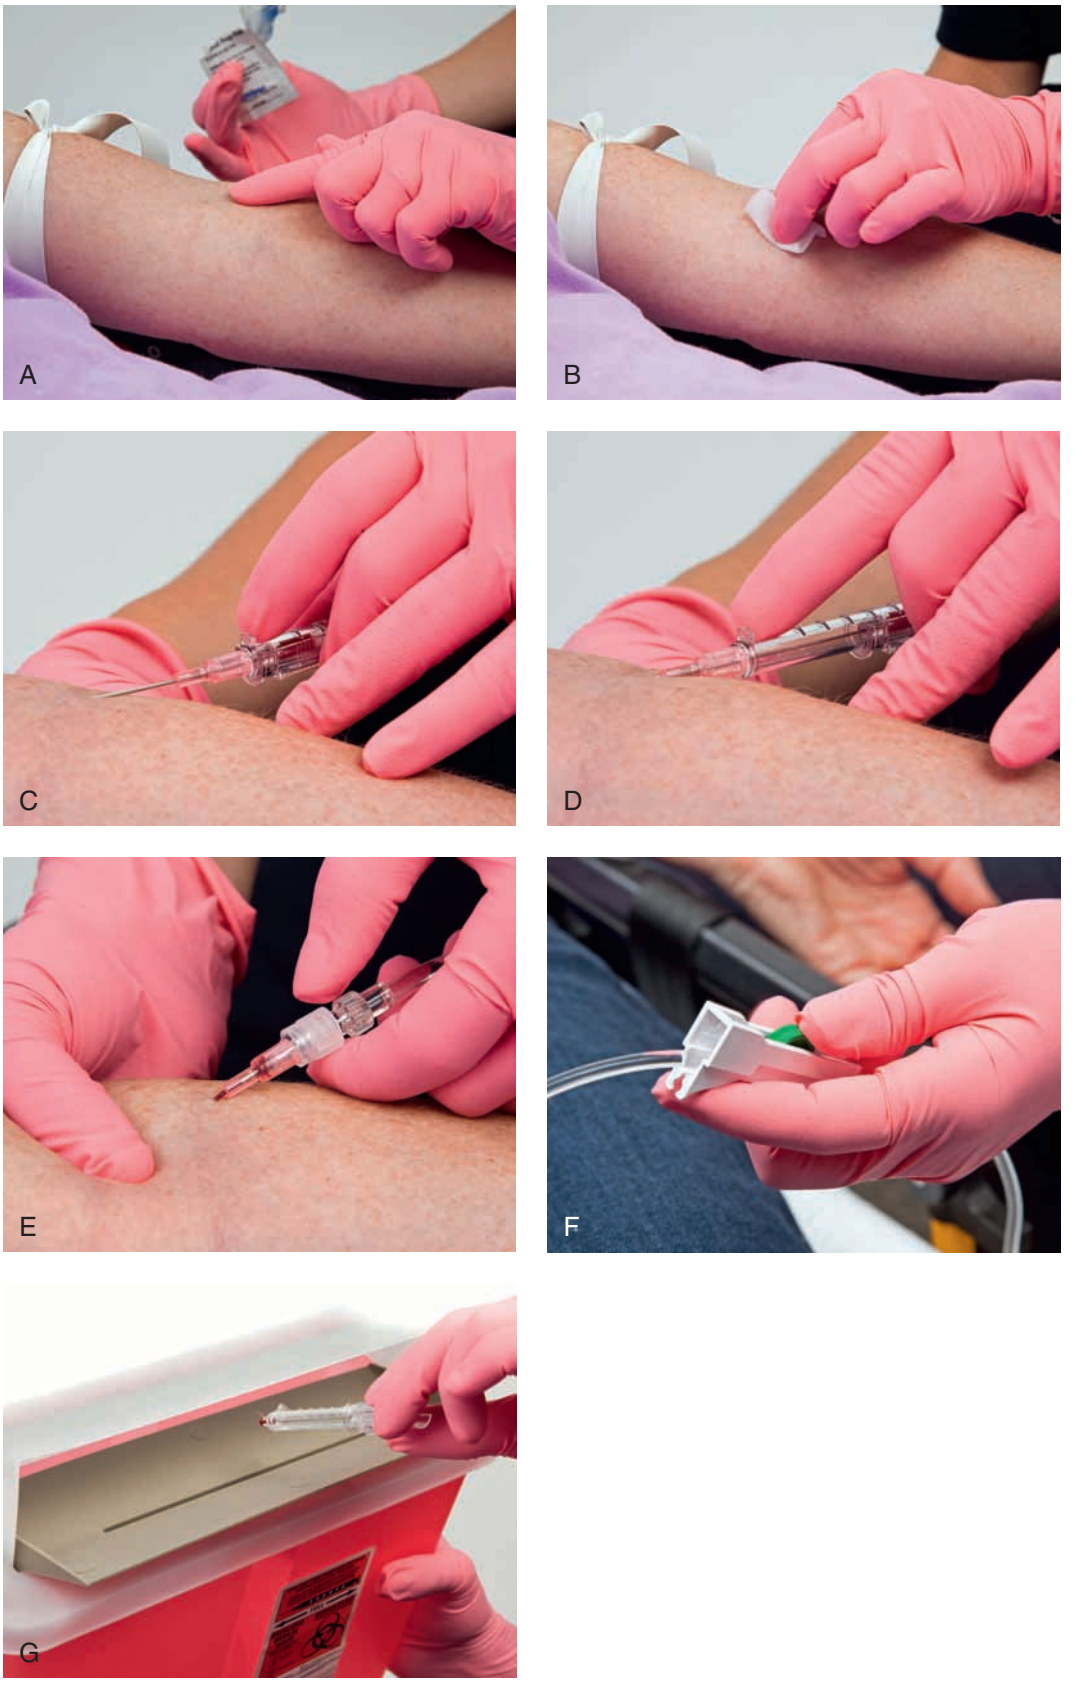

FIGURE 14-26 Intravenous (IV) catheterization technique. **A,** Apply a tourniquet above the desired site and identify the vein. **B,** Cleanse the site. **C,** Stabilize the vein and pass the needle into the vein from the side or directly on top. **D,** Slide the catheter over the needle and into the vein. While stabilizing the catheter, withdraw the needle into the protective sheath. **E,** Release the tourniquet and attach the IV tubing. **F,** Open the tubing clamp. Adjust the infusion to begin at the prescribed flow rate. **G,** Apply a dressing and secure it. Make sure the needle has been discarded in an appropriate container.

11. Cover the puncture site with an occlusive dressing to ensure asepsis and to secure the line (Figure 14-26, *G*). Anchor the tubing and secure the catheter. Catheter movement can increase the risk of phlebitis and cause migration of pathogens along the cannula into the vein.
12. Document the infusion procedure. Also, make sure the needle has been discarded in an appropriate container (Figure 14-26, *H*).

DID YOU KNOW?

Troubleshooting an Intravenous Infusion

If intravenous (IV) fluids are not flowing well or have completely stopped flowing, the paramedic should attempt to correct the problem before abandoning the IV site. Troubleshooting of an IV infusion should begin at the patient and proceed to the IV bag. The following are some common problems and solutions to consider for IV flow problems.

1. Make sure the tourniquet has been removed. If it is still in place, remove it.
2. The patient's joint above the insertion site may be flexed. Reposition the extremity or splint the extremity with a board.
3. The patient may be lying on the IV tubing, or the tubing may be kinked, restricting flow. Reposition the patient. Secure the tubing using a loop to prevent kinking.
4. Make sure the flow clamp and any other clamps are open. Adjust the clamp as needed and recalculate the drop rate.
5. The catheter tip may be lodged against the wall of the vein. Gently reposition the catheter.
6. The securing tape or device may be too tight, restricting flow. Reapply it if necessary.
7. Gravity may prevent fluid flow when the IV tubing is too far below the insertion site. Lift and reposition the IV tubing.
8. The IV bag may not be high enough above the insertion site. Raise the bag at least 3 feet above the insertion site.

If these attempts do not resolve the fluid flow problem, the IV line should be removed and another IV site should be chosen in the opposite extremity, if possible. If the insertion site is swollen or is leaking fluid into surrounding tissues (infiltration), the catheter should be removed.

Complications of Intravenous Techniques

About 25 million Americans have IV catheters placed each year.[9] Intravenous therapy is a very important part of medical treatment for acute illnesses, cancer, surgery, anesthesia, and trauma. However, it can have complications. Possible complications include local complications, systemic complications, infiltration, and air embolism.

NOTE

More than 85% of hospitalized patients receive some type of IV therapy, and many of the IV lines are established in the prehospital setting. Most lawsuits related to IV therapy involve infiltration or phlebitis.[10] To protect against litigation, it is important for paramedics to document the following:

- Type, length, and gauge of the catheter inserted
- Date and time of insertion
- Number and location of attempts
- Any complications with placement of the IV
- Name of the vein
- Type of dressing applied to the site
- How the patient tolerated the procedure
- Any comments the patient made about the insertion procedure
- Name of the person inserting the device

LOCAL COMPLICATIONS

Local complications may involve hematoma formation, thrombosis, cellulitis, phlebitis, and sloughing and necrosis of tissue.

- **Hematoma formation** is the collection of blood or fluids at the site of injection or cannulation. The hematoma usually is small enough that it resolves spontaneously. It rarely requires surgical treatment, drainage, or other interventions.
- **Thrombosis** is the formation of a blood clot (thrombus) inside a blood vessel. It occurs when the blood vessel is injured. A clot that remains in place can become a **thromboembolism** and enter the circulatory system.
- **Cellulitis** is a potentially serious bacterial infection of connective tissue. It is associated with severe inflammation of dermal and subcutaneous skin. Cellulitis can be caused by the introduction of normal skin flora after an injection or cannulation. Cellulitis appears as a swollen, red area of skin that feels hot and tender. It can spread to any part of the body. Cellulitis usually is treated with antibiotics.
- **Phlebitis** is inflammation of a vein. It is common after insertion of an IV catheter. It can result if a catheter is too large for the vein or has been left in place longer than 48 hours. Phlebitis causes localized redness and warmth at the IV site. It may extend a short distance along the course of the cannulized vein. Phlebitis increases the risk of clot formation in a vein. It is treated with antiinflammatory medicines.
- **Sloughing** and **necrosis** of tissue can occur from infiltration of some IV medicines (e.g., ***dextrose 50%, sodium bicarbonate, promethazine***). Sloughing (the separation of tissue) and necrosis (tissue death) can be prevented by taking care to choose a stable vein of adequate size for drug administration. Frequent

monitoring of the IV site for position and patency before, during, and after drug administration also is important.

SYSTEMIC COMPLICATIONS

Systemic complications include sepsis, pulmonary embolism, catheter fragment embolism, and arterial puncture.

- **Sepsis** is a bacterial infection in the bloodstream. It can be caused by the use of contaminated equipment, poor aseptic technique, and prolonged IV therapy. Signs and symptoms of sepsis include a body temperature of 100.4° F (greater than 38° C) or 96.8° F (less than 36° C), profuse sweating, nausea and vomiting, diarrhea, abdominal pain, tachycardia, hypotension, an increased white blood cell count, and altered mental status. Treatment includes the use of broad-spectrum antibiotics (see Chapter 32).
- **Pulmonary embolism** is the sudden blocking of an artery in the lung. It is caused by the collection of solid material **(embolus)** brought through the bloodstream. It also may occur as a result of air bubbles introduced through an IV catheter *(air embolism),* described later). Signs and symptoms include a sudden onset of chest pain, shortness of breath, tachycardia, and hypotension. The patient should be placed on high-concentration oxygen and a cardiac monitor and should be transported for evaluation and treatment by a physician. (Pulmonary embolism is further described in Chapter 24.)
- **Catheter fragment embolism** can occur during the insertion of an IV catheter. It can result if part of the catheter is sheared off (detached), allowing the embolus to travel in the bloodstream. It also can occur when there is motion at the cannula and the hub. An example is a catheter that is poorly secured or placed at areas of flexion. Reinsertion of a needle through the catheter during intravenous insertion can also produce a fragment embolism. Signs and symptoms include sharp pain at the insertion site, chest pain, and tachycardia. If a catheter fragment embolism is suspected, the IV should be stopped; the vein should be palpated for the catheter tip; and a venous tourniquet should be applied above the tip to prevent further movement of the fragment.

NOTE

A needle should never be reinserted through a catheter. If IV insertion fails, the catheter should be removed, and a new IV catheter should be placed. When IV therapy is discontinued, the catheter should be examined to verify that it is intact and has not been sheared.

- Most arteries lie deep within the tissues. However, some may lie close to the surface. Inadvertent arterial puncture during IV therapy is noted by the presence of pulsating and bright red blood in the catheter hub. Arteries are not suited for drug administration. In addition, arterial puncture can cause diminished blood supply to areas nourished by the affected artery. If arterial puncture occurs, the catheter should be removed and direct pressure applied to the site for at least 5 minutes. (Apply direct pressure for at least 10 minutes if the patient is on anticoagulant therapy.) A new IV should be placed. The incident should be well documented on the patient care report.

NOTE

Nerves, tendons, and ligaments can be injured during IV therapy. These injuries may be caused by improper technique or lack of knowledge of anatomy. The patient may complain of intense pain, numbness, and an electric shock–type pain if a nerve is damaged. Injuries to nerves, tendons, and ligaments may be temporary or permanent. Patient management includes removing the IV catheter; inserting a new IV line; and providing careful documentation.

INFILTRATION

Infiltration may occur when the needle or catheter has been displaced or when blood or fluid leaks from around the catheter and escapes into the tissues **(extravasation).** It also can occur if a vein is punctured more than once during initiation of IV access. Signs and symptoms include:

- Coolness of the skin at the puncture site
- Swelling at the puncture site, with or without pain
- Sluggish or absent flow rate

If infiltration is suspected, the paramedic should lower the fluid reservoir to a dependent position to check for the backflow of blood into the tubing. (The absence of backflow suggests infiltration.) If any of the signs and symptoms are present, the intravenous flow should be discontinued (Box 14-9). The needle or catheter should be removed immediately. Moreover, a pressure dressing should be applied to the site. An alternative puncture site should be chosen and the infusion restarted with new equipment. In

BOX 14-9 Discontinuation of an Intravenous Infusion

To discontinue an intravenous (IV) infusion and remove the IV catheter, follow these steps:

1. Put on gloves.
2. Carefully remove any securing tape and dressings.
3. Close the drip chamber to stop the flow of fluid.
4. Place sterile gauze over the insertion site and apply gentle pressure with one hand. With the other hand, quickly withdraw the catheter, pulling straight back from the angle of insertion. Check that the catheter is intact.
5. Apply firm pressure to the insertion site for 2 to 5 minutes to prevent bleeding or bruising.
6. Cover the insertion site with a bandage.
7. Appropriately dispose of all equipment.

addition, the incident should be documented. Medication should not be injected into an IV line if there is a possibility it has infiltrated.

AIR EMBOLISM

Air embolism is uncommon. However, it can be fatal. The volume of air the human bloodstream can tolerate has not been firmly established. However, fatalities have been reported after 100 mL of air entered the cardiovascular system.[11] A total of 10 mL of air can be fatal in a critically ill patient.

The embolism is caused by air entering the bloodstream via the catheter tubing. The risk of air embolism is greatest when a catheter is passed into the central circulation, where negative pressure may actually pull in air (see Appendix A). Air can enter the circulation either on insertion of the catheter or when the tubing is disconnected to replace solutions or add new extension tubing (Box 14-10). With subsequent pumping, blood foaming occurs in the heart. If enough air enters the heart chamber, it can impede the flow of blood. This, in turn, can lead to shock. Signs and symptoms of air embolism include hypotension, cyanosis, weak, rapid pulse, and loss of consciousness. If air embolism is suspected, the following steps should be taken:

1. Close the tubing.
2. Turn the patient on the left side with the head down. (If air has entered the heart chambers, this position may keep the air in the right side of the heart and away from the cardiac valves. The pulmonary artery may absorb small air bubbles.)
3. Check tubing for leaks.
4. Administer high-concentration oxygen.
5. Notify medical direction.

Accidental disconnection of the IV tubing can cause an air embolism. This may occur during patient movement. The chance of an air embolism can be minimized by making sure all tubing connections are secure. Also, fluid containers should be changed before they are empty.

Intravenous Medications

Medications can be given directly into the vascular system via the venous route by injection or infusion. An intravenous injection can be administered through a previously established IV infusion line, heparin or saline lock, or implantable port (e.g., Port-A-Cath, Hickman catheter). It also can be administered directly into the vein with a sterile needle or butterfly device. An IV infusion is given by adding a drug to an infusing intravenous solution. (An example of such a solution is normal saline.) Another method is to dilute the drug in a larger volume of fluid and administer the medication IV push, or through a volume control, in-line device (e.g., burette, Volutrol, infusion pump) (Figure 14-27). Sometimes the medication is given by intermittent infusion through an existing infusion site (*intravenous piggyback* or *secondary set*).

Intravenous injections normally involve a small amount of medication. These are called *intravenous push* or *intravenous bolus* medications. To give such an injection (Figure 14-28), the paramedic should clean the injection port or needleless port of the IV line with antiseptic. The medication is then injected slowly (usually over 1 to 3 minutes). The rate of injection depends on the type of medication and the patient's response. Most intravenous tubing has one-way valves to prevent the backflow of medication. If such a valve is not present or cannot be identified, the tubing above the injection site should be clamped during drug administration. After the injection, the infusion of fluids is continued.

Intravenous infusions for drug administration can take several forms. To add a medication to the fluid reservoir of an established IV line, the paramedic should follow these steps (Figure 14-29):

BOX 14-10 Replacement of Intravenous Solutions

At times a bag of intravenous (IV) fluids must be replaced during an infusion. To do this, prepare all equipment in advance and follow these steps:

1. Hold the infusing bag upside down in one hand and remove the spike chamber. Discard the old bag.
2. Quickly insert the spike chamber into the new bag and squeeze the chamber.
3. Insert an 18-gauge needle into an injection port in the IV tubing to allow air to be expelled from the tubing before it reaches the patient.
4. After the air has been expelled, remove the needle and adjust the flow rate of the infusion.
5. Document the time the IV fluids were replaced.

FIGURE 14-27 Buretrol, a volume control device. (Shade BR: *Mosby's EMT-intermediate textbook for the 1985 National Standard Curriculum,* revised edition, St Louis, 2007, Mosby.)

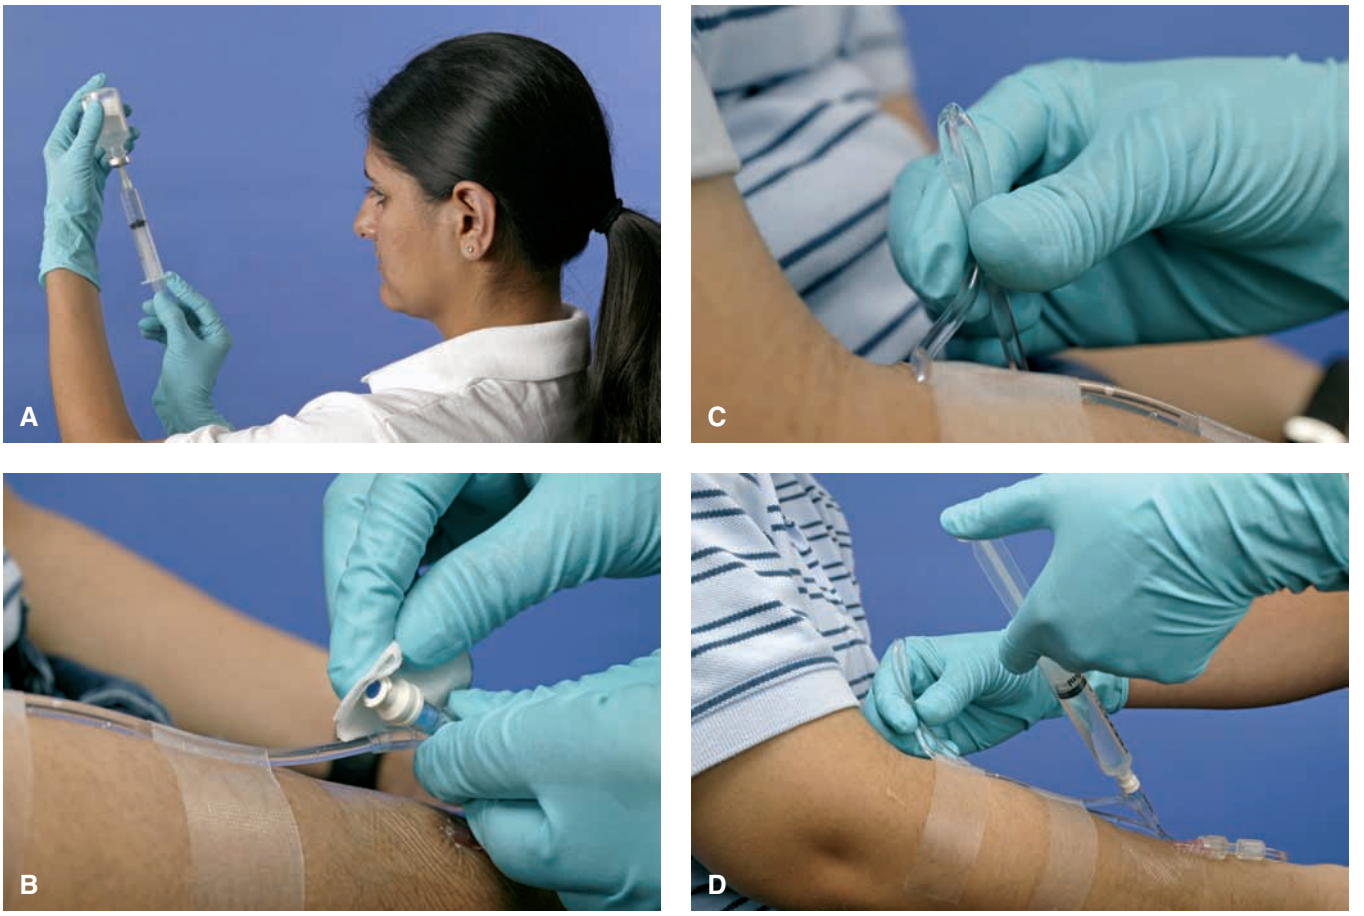

FIGURE 14-28 Administration of a drug by the intravenous (IV) route. **A,** Prepare the correct volume of the drug. **B,** Cleanse the injection port. **C,** If the tubing does not have a one-way valve, pinch the line to clamp it. **D,** Inject the drug at the recommended rate. Resume IV flow (with a small flush if indicated) and monitor the patient.

FIGURE 14-29 Adding medication to an intravenous reservoir.

1. Compute the volume of the drug to be added to the fluid reservoir.
2. Draw up the prescribed dose into a syringe. If prefilled syringes are used, note the volume of medication in the syringe and the dose to be used.
3. Cleanse the rubber sleeve of the fluid reservoir with an antiseptic.
4. Puncture the rubber sleeve (if a needle is used) and inject the prescribed medication into the fluid reservoir.
5. Withdraw the needle (if a needleless system is not used) and discard the needle and syringe. Gently mix the medication with the fluid by agitating the reservoir.
6. Label the fluid reservoir with (1) the name of the medication added, (2) the amount of the medication added, (3) the resultant concentration of the medication in the reservoir, (4) the date and time the infusion was prepared, and (5) the name of the paramedic who prepared the infusion.
7. Calculate the rate of administration in drops per minute as prescribed.

A number of in-line volume control devices allow more accurate delivery of medication diluted in precise amounts of fluids than can be achieved by simply setting the drip rate manually. These devices often are used to give intravenous medications to children and adults who need precise

FIGURE 14-30 Intravenous infusion pump.

doses. Medications that can readily cause toxicity when given too rapidly (e.g., antidysrhythmics, vasopressors) are well suited to this delivery method. In-line devices include electronic flow rate regulators that regulate fluid passage by means of a magnetically activated metal ball valve. They also include infusion pumps that exert pressure on tubing or fluid by pumping against pressure gradients. Paramedics should follow the instructions of the equipment's manufacturer. They also should become familiar with these devices before using them (Figure 14-30). Other mechanical (nonelectric) devices are available (e.g., Dial-A-Flow). These devices are used by some EMS agencies to closely regulate the flow rate.

Intermittent infusions are given via a setup that is secondary to the primary IV infusion. The piggyback medication is hung in tandem and connected to the primary setup (Figure 14-31). Most intermittent diluted drug infusions (except ***lidocaine*** and ***dopamine***) are meant to have a total infusion time of 20 or 30 minutes to 1 hour. The time depends on the drug and the patient's response. To prepare an intermittent infusion, the paramedic should follow these steps:

1. Prepare the prescribed medication. Add it to the secondary fluid as described here.
2. Bleed the air out of the secondary administration set. Attach a 1-inch, 18-gauge needle if a needleless system is not available.
3. Cleanse the medication port of the primary infusion tubing. Insert the needle or insert the tubing from the piggyback medication.
4. Tape the needle (if present) or carefully secure the tubing to the medication port.

FIGURE 14-31 Intravenous piggyback setup.

5. Calculate the flow rate of the secondary infusion in drops per minute.
6. Lower the primary infusion reservoir so that its center of gravity is lower than the secondary infusion reservoir.
7. Clamp the tubing of the primary infusion to allow the piggyback medication to infuse. Open the piggyback line flow clamp. Adjust the flow rate to the desired dose. After administration of the piggyback medication, restart the primary infusion. Discard the piggyback equipment.
8. Always label the bag with the medication.
9. Document the effect on the patient.

Another device used to administer a drug intravenously is a drug pump. Drug pumps are used by patients who need a slow injection of medication in the home. Examples may be patients who are undergoing cancer chemotherapy, patient-controlled analgesia, and insulin pumps. These devices may consist of a syringe with a battery attachment, a pager device, or a large pump that regulates the injection of medication. Drug pumps are used to give medication subcutaneously, intravenously, or in some cases, into the epidural space. They also can be attached to indwelling

BOX 14-11 Indwelling Vascular Devices

Heparin or Saline Lock

A heparin or saline lock is a peripheral intravenous (IV) cannula. It has no attached IV tubing (Figure 14-32). These devices allow ready access to peripheral veins. They are used for brief administration of medications. They also are used for IV therapy that is administered frequently on an outpatient basis (e.g., chemotherapy). The cannula is filled with 0.5 to 1 mL of a heparin or saline solution. This prevents clotting when the device is not in use.

To gain access to the peripheral vein, draw 4 mL of normal saline into a syringe. Use aseptic technique. Flush 2 mL of the normal saline through the heparin lock reservoir before and after infusion of the prescribed medication or IV fluid. After IV therapy, inject 0.5 to 1 mL of heparin or 3 mL of 0.9% normal saline into the reservoir. This keeps the lock patent.

Central Venous Access Devices (CVADs)

There are four types of CVADs: nontunneled catheters, tunneled catheters, peripherally inserted central catheters (PICCs), and implanted ports (Figure 14-33). The tip of the CVAD rests in the superior vena cava (the tip of a femoral CVAD is in the inferior vena cava). If the tip moves into the atria, complications can occur. Nontunneled CVADs are inserted through the skin into the subclavian vein. They can be inserted in an emergency. Tunneled CVADs are silicone catheters inserted into the subclavian vein in the operating room or radiographic procedure room. They are designed to stay in place for years. Examples of tunneled CVADs include Hickman, Broviac, Groshong, Hohn, and Leonard catheters. Peripherally inserted central catheters usually are introduced through a vein in the antecubital fossa. They are designed for short-term treatment (up to 6 months). Because they are longer than the other CVADs, drawing blood or infusing fluids quickly through these lines sometimes is more difficult.

Most CVADs have a volume of 1 to 3 mL. Be careful not to introduce air when drawing blood, administering drugs, or initiating IV fluids, because an air embolus could result. Follow these steps to access a tunneled, nontunneled, or peripherally inserted CVAD:

1. Prepare the equipment (use only 10 mL or larger syringes; smaller syringes can create high pressure and damage the catheter).
2. Draw up 3 to 5 mL of normal saline (at least twice the volume of the catheter).
3. Put on gloves. Use aseptic technique.
4. Explain the procedure to the patient.
5. Clamp the catheter with the attached clamp or padded smooth shunt clamp (Groshong catheters have a built-in valve and should not be clamped).
6. Wipe the site with povidone-iodine and allow it to dry.
7. Connect the syringe and unclamp the catheter. Withdraw 5 mL blood **(if blood cannot be withdrawn, do not use the catheter).**
8. Replace the clamp.
9. Attach the syringe of normal saline to the catheter. Remove the clamp and flush (do not use excessive pressure).
10. Replace the clamp and remove the syringe.
11. Connect the IV tubing to the catheter. Make sure the tubing is free of air.
12. Remove the clamp and begin the infusion.
13. Tape the connection site between the tubing and catheter. Administer fluids and drugs.

Implantable Ports

An implantable port is a CVAD that is surgically inserted in a pocket under the skin (Figure 14-34). It has a self-sealing septum over a small chamber or reservoir. Each time the port is used, the skin must be punctured by a needle. A regular needle could damage the port, requiring immediate surgery. A special, noncoring Huber needle should be used. Implantable ports should not be accessed in the ambulance if the patient is stable. If the septum is punctured or the port becomes infected, a surgical technique is needed to replace it. The steps for accessing the port are as follows:

1. Palpate the skin and locate the port.
2. Use sterile technique to clean the area with alcohol and then povidone-iodine.
3. Feel for the edge of the port housing and stabilize the port with one hand.
4. Insert the Huber needle through the skin and port septum until contact is made with the back of the port.
5. Confirm correct placement by aspirating blood.
6. Flush with saline and connect the IV tubing (make sure it is free of air).
7. Cover the Huber needle with a transparent dressing. Start the infusion.

NOTE

To prevent damage to central venous catheters, paramedics should:

- Use a clamp on the clamping sleeve provided on silicone catheters
- Avoid using scissors or other sharp objects around the device
- Use only small-gauge needles (22 to 25 gauge) with a needle length of 1 inch or less when accessing the injection port
- Administer fluids or medications gently (never force them)

vascular devices such as the Port-A-Cath or Hickman catheter (Box 14-11).

Intraosseous Medications

Studies have shown that intraosseous (IO) infusion is relatively safe and effective in both children and adults.[8] Fluids and drugs infused through IO access pass quickly from the marrow cavities of long bones into the sinusoids. Then they pass to large venous channels and emissary veins. Next, they pass into the systemic circulation. Normal saline, lactated

FIGURE 14-32 Saline lock.

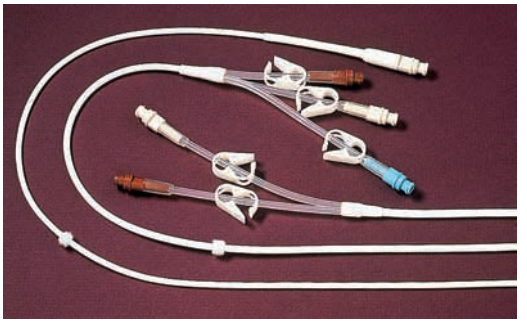

FIGURE 14-33 Single-lumen, dual-lumen, and triple-lumen central venous access device (CVAD) catheters.

Ringer solution, D_5W, plasma, blood, and most advanced life support (ALS) medications may be infused quickly by this route (Figure 14-35). Drugs administered by the IO route should be followed by a saline flush of at least 5 mL. This ensures that the drug is delivered into the central circulation.

IO infusion is indicated in ill or injured patients who require vascular access for drugs or fluids when peripheral cannulation is difficult or unobtainable.[12] Examples include cardiopulmonary arrest and peripheral vascular collapse (as in shock, major trauma, or burns). The procedure also may be indicated in patients in whom vascular access is impaired by obesity or edema and in patients with life-threatening status asthmaticus. Status asthmaticus is an acute exacerbation of asthma that does not respond to standard treatments (see Chapter 24).

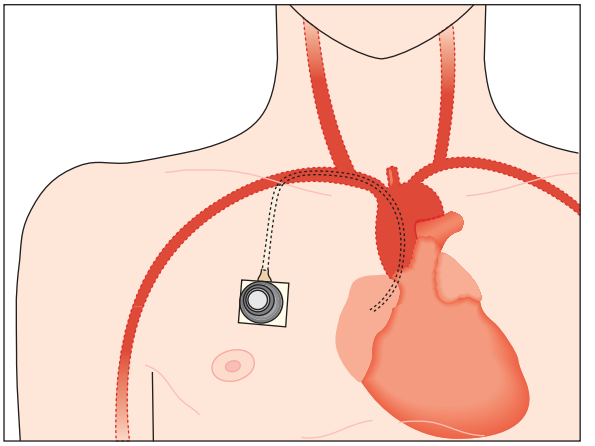

FIGURE 14-34 Port-A-Cath.

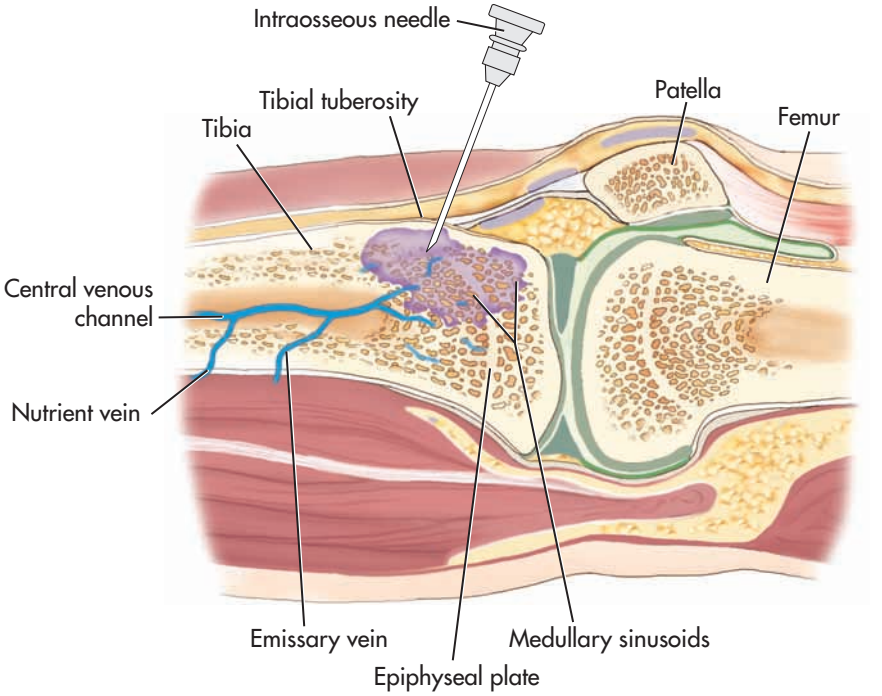

FIGURE 14-35 Obtaining intraosseous access.

FIGURE 14-36 EZ-IO access. (Courtesy Vidacare Corp., San Antonio, Texas.)

NOTE
The intraosseous (IO) space can be thought of as a "noncollapsible vein." This space is surrounded by bone and is directly connected to the central circulation. In the absence of trauma to the bone, the IO space remains patent, even when peripheral veins collapse.

The site of choice for initiation of this procedure is the tibia, just below the tubercle on the anteromedial surface. Alternative sites in children are the femur, just above the lateral condyles in the midline. In adults, alternative sites are the sternum, just below the sternal notch; the tibia; the medial malleolus; and the head of the humerus. Regardless of the insertion site chosen, the IO procedure requires special IO devices. This is especially true in adults, whose bones are more difficult to penetrate than the bones of children. These devices are designed to insert the IO needle safely through the cortex into the marrow of long bones. A number of commercial IO devices are available. These include the Bone Injection Gun (BIG), Cook Disposable IO Infusion Needle (Sur-Fast Needle), EZ-IO infusion system (Figure 14-36), First Access for Shock and Trauma (F.A.S.T.1) IO infusion system, the Jamshidi IO needle, and others. Paramedics should carefully follow the manufacturer's recommendations when using these devices. The procedures for initiating IO infusion in the tibia of a child are shown in Figure 14-37.

NECESSARY EQUIPMENT FOR IO INFUSION

- Antiseptic
- Tape
- Bone marrow needle or commercial intraosseous needle
- IV tubing (pediatric infusion set)
- IV fluids (specified by medical direction): normal saline, lactated Ringer solution, or special pediatric fluids
- Pressure infusion bag or pump

INSERTION TECHNIQUE (FIGURE 14-37)

1. Put on gloves for personal and patient protection.
2. Cleanse the site as previously described for peripheral cannulation.
3. Prepare the needle for insertion. Insert the needle pointing away from the epiphyseal plate. Advance it to the periosteum.
4. Using a boring or screwing motion (or the device-specific technique), advance the needle until it penetrates the bone marrow (usually noted by decreased resistance and a slight popping sound).
5. Remove the stylet.
6. Aspirate bone marrow into a saline-filled syringe. (Bone marrow may not always be aspirated.)
7. Infuse saline by syringe to ensure placement of the needle and to clear clots.
8. Secure the needle with tape and a securing screw if so equipped (although the needle usually is well stabilized by the bone).
9. Attach standard IV tubing and fluids to infuse under gravity or pressure as prescribed by medical direction.
10. Apply a dressing to the site.
11. Document the procedure.

CONTRAINDICATIONS

- Fracture of the site or proximal to the site
- Traumatized extremity
- Cellulitis
- Burns that may be infected by the technique
- Congenital bone disease

POTENTIAL COMPLICATIONS

Technical Complications

- Subperiosteal infusion from improper placement
- Penetration of posterior wall of medullary cavity, resulting in soft tissue infusion
- Slow infusion from clotting of marrow

Systemic Complications. IO devices are short-term emergency devices. They usually are removed within 24 hours of insertion to prevent systemic complications.

- Osteomyelitis (occurs in fewer than 0.6% of cases, usually with prolonged infusion)
- Fat embolism (rare)
- Slight periostitis at the injection site (usually clears within 2 to 3 weeks)
- Infection (acceptably low rate, comparable to that with other infusion techniques)
- Fracture

ADMINISTRATION OF PERCUTANEOUS MEDICATIONS

Percutaneous drug administration is the administration of drugs that are absorbed through the mucous membranes or skin. These include topical drugs, sublingual drugs, buccal drugs, inhaled drugs, endotracheal drugs, nasal drugs, and drugs for the eye and ear.

Topical Drugs

In addition to the various emollients and antibiotic ointments, the most commonly used transdermal emergency

FIGURE 14-37 Intraosseous infusion. **A**, Assess the site, **B**, Cleanse the site. **C**, Using a screwing motion, insert the bone marrow needle away from the epiphyseal plate. Advance the needle until a pop is felt (this occurs when the needle penetrates the marrow). **C**, Remove the stylet. **D**, Aspirate for marrow and then flush with saline. **E**, **F**, Attach the intravenous tubing and adjust the infusion to the prescribed flow rate. Check for signs of infiltration.

medication is ***nitroglycerin.*** Two types of topical nitroglycerin preparations are available: ***nitropaste*** and transdermal ***nitroglycerin*** delivery patches. These can be applied to any clean, dry area of the upper arm or hair-free portion of the chest. ***Nitropaste*** has a lanolin-petrolatum base. It is applied in ½-inch increments with special papers to measure the dose. Transdermal ***nitroglycerin*** patches have an adhesive back (Figure 14-38). They are available in a solid or semisolid form, depending on the manufacturer. Paramedics should always wear gloves when applying or removing these medications to prevent inadvertent self-absorption of the drug. (More information is available in the *Emergency Drug Index*.) The onset of drug action for transdermal medications is slower and the duration is longer.

FIGURE 14-38 Application of a nitroglycerin patch.

Drugs such as ***fentanyl,*** scopolamine, clonidine, and estrogen are also used in patch form. These drug patches can affect the patient unfavorably during illness. Paramedics should be able to recognize the different types of patches and should remove them if indicated. Usual sites for the patches are behind the ear and on the chest, back, hip, and upper arms.

Sublingual Drugs

The most frequently prescribed sublingual (SL) drugs are nitrates (e.g., ***nitroglycerin***), which are used to treat angina pectoris. Other SL drugs used in emergency care are ***lorazepam,*** which is used to treat anxiety, and ***captopril,*** which is used to manage congestive heart failure. Sublingual tablets should be placed under the tongue, where they dissolve. The patient should not drink fluids while the drug is being absorbed. If the patient inadvertently swallows the tablet, the effects are diminished and delayed. It should be noted that older adults have decreased saliva. Therefore, absorption can be slow and unpredictable in these patients.

Buccal Drugs

Buccal drugs are held between the patient's cheek and gum. They dissolve to achieve their desired effects. As with sublingual drugs, the patient should not drink fluids while the drug is being absorbed. Glucose gel preparations are an example of an emergency medication administered via the buccal route. This route should not be used for patients with altered level of consciousness. It should also not be used in patients who cannot swallow or who have an ineffective gag reflex.

Inhaled Drugs

In addition to oxygen and ***nitrous oxide,*** several other drugs may be administered by means of inhalation. These include bronchodilators, corticosteroids, antibiotics, and mucokinetic agents delivered through aerosolization.

Aerosols are liquid or solid particles of a substance dispersed in gas or solution. The effectiveness of aerosolization therapy depends on the number of droplets that can be suspended in the gas or solution, the rate of oxygen or gas flow, the particle size (diameter in microns), output (cc/min), and the rate and depth of the patient's breathing. Rapid, shallow breathing reduces the number and retention of droplets that reach the deep bronchioles of the lungs. The delivery of drugs by this method has certain advantages over other routes. Specifically, these are rapid onset of the drug's effect and fewer or less intense systemic side effects.

Aerosols are made by devices called *nebulizers*. Intermittent positive pressure breathing (IPPB) devices are designed for in-hospital use. Out-of-hospital devices include metered-dose inhalers (pressure cartridges) and handheld nebulizers. Handheld nebulizers operate by means of a compressed air or oxygen source regulated by a flowmeter.

METERED-DOSE INHALER

The metered-dose inhaler (MDI) is now the most commonly used device in aerosol therapy (Figure 14-39). It is convenient and delivers a measured dose with each push of the cartridge. MDIs usually are prescribed for self-treatment of asthma. Other medications prepared in MDIs are ***ipratropium,*** and ***albuterol.*** Paramedics should follow these steps to administer a drug by this method:

1. Remove the mouthpiece and protective cap from the canister (the drug container).
2. Carefully snap off the cap and turn the mouthpiece sideways.
3. Insert the canister stem into the hole inside the mouthpiece.
4. Shake the canister and mouthpiece well.
5. Invert the MDI and hold it close to the patient's mouth. Instruct the patient to exhale, pushing as much air from the lungs as possible.
6. Place the mouthpiece in the patient's mouth. Instruct the patient to close the lips loosely around it, with the tongue underneath the mouthpiece. As the patient inhales deeply over 5 seconds, press down on the canister quickly and then release it.

FIGURE 14-39 **A,** Metered-dose inhalers (MDIs). **B,** Metered-dose inhaler with an extender or spacer. (Clayton BD, Stock YN, Cooper S: *Basic pharmacology for nurses,* ed 15, St Louis, 2010, Mosby.)

7. Instruct the patient to hold his or her breath 5 to 10 seconds before exhaling.
8. Repeat the procedure in 5 to 10 minutes to take advantage of possibly deeper penetration by a second round of therapy (if required). Most MDI medications are administered using aerochambers (spacers). These are beneficial devices for children and for patients with problematic conditions. For example, some patients might need additional time to inhale the medication. Others may lack coordination. Still others may be hampered by a high level of anxiety or by a diminished ability to inhale for 5 seconds. Aerochambers allow the patient to receive the maximum benefit of the drug and do not require exact synchronization.

CRITICAL THINKING
What happens to the medication if the patient does not use the metered-dose inhaler (MDI) properly?

HANDHELD NEBULIZERS

Handheld nebulizers are another means of administering some medications via inhalation in the prehospital setting. Various manufacturers make disposable nebulizer kits. The kits usually include a mouthpiece or aerosol mask, oxygen tubing, and reservoir tubing (Figure 14-40). These devices are attached to a nonhumidified portable or on-board oxygen source. They use the Bernoulli principle to create an aerosol mist (sometimes referred to as a *jet* or *pneumatic nebulizer*). Medications appropriate for nebulization therapy include ***albuterol, atropine, ipratropium, levalbuterol,*** and ***metaproterenol***.

The specific procedure may vary slightly. It may depend on the patient's ability to tolerate the treatment by mouthpiece or mask. A tight seal around the mouthpiece is required. The patient therefore must be able to cooperate during treatment. Both mouthpiece and mask methods have advantages. With treatment by mouthpiece, less of the drug is wasted. However, patients with severe dyspnea who are mouth breathers tolerate mask administration much better.

FIGURE 14-40 Administration of medication with a handheld nebulizer.

To administer a medication with a handheld nebulizer, paramedics should follow these steps:

1. Using aseptic technique, mix the prescribed drug with a specified amount of normal saline. Then instill it into the nebulizer. Some medications come in a packaged unit dose and have a fixed amount of diluent (usually 0.9% normal saline).
2. Attach the nebulizer to a T-piece and mouthpiece and connect it with tubing to the unit delivering nonhumidified oxygen (for the hypoxic patient) or compressed air. (If the patient cannot use the mouthpiece, a simple face mask may be used in its place.)
3. Adjust the oxygen flowmeter to a rate of 4 to 6 L/min to create a steady, visible mist. (This rate usually offers a steady mist without too much wastage of medication. The higher the flow rate, the greater the medication use.) If an aerosol mask is used, the oxygen flow rate should be kept at 6 to 8 L/min. This prevents the buildup of exhaled carbon dioxide in the mask.
4. When the mist is visible, begin treatment. Instruct the patient to inhale slowly and deeply by mouth. Have the person hold a breath for 3 to 5 seconds before exhaling. This results in topical deposition of the aerosol particles deep within the tracheobronchial tree. Inhalation and exhalation should be continued until the aerosol canister is depleted of the medication. Repeat treatments usually are not given more often than every 15 to 20 minutes (usually to a maximum of three). Treatment of severe asthma, however, may include continuous administration of nebulized beta agonists, tailored to the patient's response.

The patient must be cooperative to undergo nebulization therapy. The individual must be able to follow instructions to breathe deeply so that the drug can be absorbed. This therapy would be ineffective if the patient is unable to inhale the drug sufficiently or if bronchospasm is too severe. In such cases, administration via another route should be considered. Nebulizer treatments may be administered to a patient who is artificially ventilated by placing it into the ventilation circuit of the bag-valve-mask (BVM) or ventilator.

Notable changes in the heart rate or dysrhythmias may occur during nebulization therapy. If these occur, treatment should be stopped and medical direction should be contacted for further orders. Paramedics and ambulance crews should avoid the medication vapor stream during nebulization therapy.

Endotracheal Drugs

The endotracheal (ET) route is an alternative route of drug administration. It may be used when IV or IO access cannot

be established. (Absorption through the ET route is unpredictable and less effective than the IV or IO routes; therefore, the ET drug dose must be increased.) Emergency drugs that may be administered by this route are ***naloxone, atropine, vasopressin, epinephrine,*** and ***lidocaine.*** (Memory aid: N-A-V-E-L) When giving medication by this route, paramedics should follow these steps (Figure 14-41):

1. Make sure the ET tube is in the correct position. This can be checked by direct visualization and by auscultation (see Chapter 15).
2. Make sure oxygenation and ventilation of the patient's lungs are adequate.
3. Prepare the medication so that it is 2 to 2½ times the intravenous dose. Dilute the dose to 10 mL with normal saline (or prepare a 10 mL normal saline flush, per protocol).
4. Remove the air source from the ET tube. Inject the medication through a catheter deep into the tube or inject it directly into the tube and follow with a normal saline flush (per protocol). (Some ET tubes have a drug port; with these tubes, the air source need not be removed for drug administration.)
5. Resume ventilations with one to two full ventilations. This helps ensure that the medication penetrates as deeply as possible into the pulmonary tree (which enhances absorption).
6. Monitor the patient for the desired therapeutic effect and for any side effects.

Drugs for the Eye, Nose, and Ear

Eye medications usually are supplied in the form of drops or ointments. To administer these drugs, the paramedic should have the patient lie down or sit with the head tilted back. Stabilizing the patient's head with one hand, the paramedic uses the thumb or fingers of the other hand to pull down the lower lid gently. The medication should be applied into the conjunctival sac of the lower lid, never onto the eyeball (Figure 14-42).

FIGURE 14-41 Administration of a drug through an endotracheal (ET) tube.

Nose drops are best administered with the patient lying down with the head over the edge of a bed in a midline position. The drops are instilled into each nostril. The patient should be instructed not to blow the nose for several minutes to allow absorption of the drug. To administer a drug via the nasal route, the paramedic should instruct the patient to hold the head upright or tilted back and to block one nostril. The patient then inhales through the open nostril while squeezing the spray applicator to release the atomized drug (Figure 14-43).

NOTE

Giving atomized nasal drugs has some advantages. For example, because the nasal route is needleless, the risk of needle-stick injury is eliminated. Also, nasal drugs can be administered safely in a moving ambulance or rescue vehicle. The nasal route may be preferred with combative patients and small children and when IV access is difficult to obtain.

Many emergency medications have been approved for nasal administration. Examples include diazepam (Valium), fentanyl (Sublimaze) glucagon, haloperidol (Haldol), lidocaine (Xylocaine), lorazepam (Ativan), midazolam (Versed), and naloxone (Narcan). *Any drug that can cause hypotension should not be administered intranasally without an established IV line.*

FIGURE 14-42 Administration of eye medication.

FIGURE 14-43 Nasal administration of naloxone.

Ear medications usually are provided in the form of drops. The patient should lie down with the affected ear up. With adults or children over age 3, the paramedic should gently pull the top of the ear up and back to straighten the ear canal. The prescribed number of drops is then instilled. In children under age 3, the ear is pulled down and straight back. The patient should remain in the ear-up position for about 10 minutes to allow the medicine to disperse. To prevent contamination of the drops, the paramedic should not allow the tip of the dropper to come into contact with the ear canal. Placing a cotton ball in the ear canal after administration of the drug may reduce seepage of the drops onto the face.

SHOW ME THE EVIDENCE

Barton and coworkers prospectively studied the effectiveness of administering intranasal (IN) naloxone to unconscious prehospital patients in Denver. Of the 30 patients studied, 11 responded either to intravenous (IV) or to IN naloxone. Ten responded to IN naloxone alone, with an average response time of 3.4 minutes. Seven of these patients did not require IV therapy. The authors conclude that the intranasal route should be considered for treatment of suspected overdose in the prehospital setting. Use of this route avoids the use of needles and may reduce the risk of exposure to blood-borne pathogens.

From Barton E et al: Intranasal administration of naloxone by paramedics, *Prehosp Emerg Care* 6:54-58, 2002.

SPECIAL CONSIDERATIONS FOR PEDIATRIC PATIENTS

Administering drugs to infants and children can be quite difficult. This is especially true in emergency situations. The following guidelines may be helpful for this process.

- Try to establish a positive relationship with the child. Accept fearful or anxious behavior as a natural response.
- Be honest with the child when explaining a medication or procedure that will be unpleasant or painful.
- If appropriate, allow the child to help administer the medication (e.g., by holding the medicine cup or by placing a pill in the mouth).
- When administering oral liquid drugs to infants or small children, hold the child (or have the parent hold the child) in a semireclined position. Place the oral medication syringe or administration device alongside the tongue. Slowly inject the medication, allowing the child to swallow small amounts at a time.
- Use mild physical restraint only if it is required. Explain to the child why it is needed.
- Enlist the assistance of parents or other caregivers when possible.
- When parenteral medications are required, stabilize the injection site well and give the injection quickly. Two or more individuals should be available to hold a child over 4 years of age, even if the child promises to "be still."
- Remember when administering medications that the younger and smaller the child, the smaller the margin for error.

SHOW ME THE EVIDENCE

Pediatric medication doses are calculated according to the patient's weight. Bernius and colleagues recognized that this increases the risk of drug dose errors. They evaluated whether the use of a protocol-specific pediatric code card resulted in more accurate drug dose and volume calculation by prehospital care providers. They evaluated drug dose calculation in 523 advanced life support (ALS) providers during training in Maryland and the District of Columbia. For the 246 who used the code card, the mean correct response rate was 94%; for the 277 who did not use the card, the rate was 65%.

From Bernius M et al: Prevention of pediatric drug calculation errors by prehospital care providers, *Prehosp Emerg Care* 12:486-494, 2008.

OBTAINING A BLOOD SAMPLE

Venous blood samples often are obtained in the prehospital setting for glucose testing and for laboratory determinations performed in the hospital. If possible, these samples should be obtained when an IV line is established and always before any fluids are infused. When obtaining a blood sample from an IV site, the paramedic should follow these steps:

1. Prepare all equipment in advance.
2. After removing the needle from the IV catheter, exert manual pressure above the IV site to prevent the free flow of blood from the catheter.
3. While stabilizing the site, insert the Vacutainer into the hub of the IV catheter.
4. Push blood collection vacuum tubes (Table 14-3) into the barrel of the Vacutainer to draw blood from the IV catheter.
5. After obtaining the required specimens, attach the IV tubing and begin infusion.
6. Label the sample with the patient's name and the time and date it was obtained.

CRITICAL THINKING

Why should a venous blood sample never be drawn above an IV infusion site?

If no IV line is to be used, the paramedic must obtain the blood sample using a Vacutainer (Figure 14-44) or a needle and syringe and then transfer the sample to an evacuation tube. The steps for obtaining a blood sample using a needle and syringe are as follows:

1. Apply a tourniquet above the selected site.
2. Cleanse the site as previously described for venipuncture.
3. Using an 18- or 20-gauge needle attached to a 10- or 12-mL syringe, enter the vein.

TABLE 14-3 Types of Blood Sample Tubes and Order of Blood Draws

To prevent contamination of tubes with additives from other tubes, it is important to draw the tubes in a *specific* order. This called the *order of the draw.* The following is the collection sequence for evacuated tubes when multiple tubes must be drawn[13]:

1. Yellow top or bottles: Sterile/blood cultures
2. Royal blue: Red label for trace metal analysis
3. Light blue coagulation tube (If only coagulation tests are ordered *and* a butterfly catheter is used, draw a discard tube to collect the air in the tubing. If this is not done, a short draw (insufficient amount of blood for the sample) results, which will be rejected by the laboratory.)
4. Red: Nonadditive
5. Red Gel separator tube (speckled or "tiger" top)
6. Green (heparin)
7. Green/gray mottled plasma separator tube (PST) with heparin
8. Lavender/purple top and/or pink (ethylenediamine tetraacetic acid [EDTA])
9. Gray top (oxalate/fluoride tube)

Stopper Color	Additive/ Preservative	Tests Done on Blood Sample	Comments
Green 	Heparin	Electrolytes, glucose; cardiac enzymes	Invert tube several times. Heparin prevents blood from clotting without killing cells.
Gray	Oxalate/fluoride	Blood alcohol Lactate levels Fasting glucose assays	
Lavender 	EDTA anticoagulant	Blood cell count, hemoglobin (Hb), hematocrit (Hct), erythrocyte sedimentation rate (ESR) Glycohemoglobin A1C T8 for human immunodeficiency virus (HIV)	Invert tube several times to prevent clotting (do not shake). EDTA tubes are used to collect samples for whole-blood hematology testing.
Light blue 	Sodium citrate	Prothrombin time (PT), activated partial thrombin time (aPTT), fibrinogen levels D-dimer	Tube must be filled completely. Invert tube several times to prevent clotting. Sodium citrate tubes are used to collect samples primarily for coagulation studies. Such tests often are needed for patients with bleeding problems (e.g., in the abdomen, brain, or elsewhere).
Red 	None	Serum electrolytes, liver and other enzymes, therapeutic drug levels, blood bank procedures	The tube need not be inverted, because the objective is to produce a clot. Some companies make tubes with clot activators, which hasten clotting to speed testing.
Yellow 	Glass particles to speed up clotting process	All immunology tests	Tubes with clot activators

Primary Source: Becton, Dickinson: *BD Vacutainer venous blood collection: tube guide.* www.bd.com/vacutainer. Accessed August 1, 2010.

FIGURE 14-44 Obtaining a blood sample with a Vacutainer.

4. With an even, steady motion, draw back on the plunger to obtain the sample.
5. After the sample has been obtained, release the tourniquet, withdraw the needle, and apply manual pressure to the site.
6. Immediately transfer the sample to the appropriate evacuation tube. Do not force additional blood into the tube; each tube has the correct amount of vacuum for the amount of blood required in the vial. Forcing blood into a vacuum tube can cause expulsion of contents and can lead to unnecessary injury or exposure to contents.

FIGURE 14-45 Disposal of a needle in a sharps container.

7. Label the sample with the patient's name and the time and date it was obtained.

DISPOSAL OF CONTAMINATED ITEMS AND SHARPS

Needles and other sharp objects can injure the patient, the paramedic, coworkers, and others. They also can be a source of infection with hepatitis or the human immunodeficiency virus (HIV). The CDC recommends that needles not be capped, bent, or broken before disposal. Rather, they should be discarded with the syringe intact in a special container (i.e., sharps container) that is clearly marked (Figure 14-45). These containers should be puncture proof and leak proof. When full (as indicated by the "Full line," which usually is no more than three fourths of the space), the container should be discarded according to established policies for disposition of contaminated items and sharps.

SUMMARY

- Three systems for measuring drug dosage are in use today. These are the metric system, the apothecary system (no longer recommended), and the common household system. Each system deals with units of mass and volume. Any of these three systems may be used by a physician when ordering drugs.
- Paramedics should choose a drug calculation method that is precise. It also should be reliable. Paramedics should
  (1) Convert all units of measure to the same size and system
  (2) Assess the computed dosage to determine whether it is reasonable
  (3) Use one method of dose calculation consistently
- Many drug calculations can be performed almost intuitively. Nevertheless, paramedics should never rely on intuitive calculations. Methods of calculation include the basic formula (desire over have), ratios and proportions, and dimensional analysis.
- Intravenous flow rates can be calculated using the following formula:

$$\text{Drops/min} = \frac{\text{Volume to be infused} \times \text{Drops/mL of infusion set}}{\text{Total time of infusion (min)}}$$

- Safety procedures should be a high priority during the administration of any medication. The paramedic must make sure the *right* patient receives the *right* dose of the *right* drug via the *right* route at the *right* time.
- A medication error may occur. In such a case, paramedics should take responsibility for their actions. They should quickly advise medical direction. They also should assess and monitor the patient for effects of the drug. They must document the error as required by local, state, and medical direction policies. In addition, they must change their personal practice to prevent a similar error in the future.

Continued

- Medical asepsis is accomplished by using clean technique, which involves hygienic measures, cleaning agents, antiseptics, disinfectants, and barrier fields.
- Enteral drugs are administered and absorbed through the gastrointestinal tract. They are given by the oral, gastric, and rectal routes. Parenteral drugs are administered outside the intestine. They are usually injected. Parenteral drugs are given by the intradermal, subcutaneous, intramuscular, intravenous, and intraosseous routes.
- In the prehospital setting, the route of choice for fluid replacement is through a peripheral vein in an extremity. The over-the-needle catheter generally is preferred in this setting.
- Several possible complications are associated with all intravenous techniques. These include local complications, systemic complications, infiltration, and air embolism.
- Fluids and drugs that are infused by the intraosseous route pass from the marrow cavities into the sinusoids. Next, they pass into large venous channels and emissary veins. Then they pass into the systemic circulation. The site of choice for IO infusions in children is the tibia, one to two fingerbreadths below the tubercle on the anteromedial surface. Other sites for IO infusions include the distal tibia, humerus, and sternum (adults).
- Percutaneous drugs are absorbed through the mucous membranes or skin. These include topical drugs, sublingual drugs, buccal drugs, inhaled drugs, endotracheal drugs, nasal drugs and drugs for the eye and ear.
- Administering drugs to infants and children can be quite difficult. This often is especially true in emergency situations. Paramedics frequently calculate pediatric drug doses by using memory aids. Some of these aids include charts, tapes, and dosage books. Doses also are calculated with the advice of medical direction.
- If possible, venous blood samples should be obtained when intravenous access is established. They also should be obtained before any fluids are infused. If no IV line is to be used and a blood sample is still needed, it must be obtained with a needle and syringe (or a special vacuum needle and sleeve).
- The CDC recommends that needles not be capped, bent, or broken before disposal. Rather, they should be left on the syringe and discarded in an appropriate, clearly marked container that is puncture proof and leak proof.

APPENDIX

Universal Precautions and Standard Precautions: Measures to Prevent Disease Transmission[17]

Universal precautions (i.e., universal blood and body fluid precautions) were developed by the Centers for Disease Control and Prevention (CDC) in 1987. They are the minimum standard of practice recommended by the Occupational Safety and Health Act of 1991 and by all health care agencies.

Universal precautions should be used in the care of all patients. However, they are especially important for paramedics and others who work in emergency care. These health care professionals face a higher risk of exposure to blood. Also, the patient's infection status usually is unknown at this point. The following are the procedures for universal precautions.[14]

1. All health care workers should routinely use appropriate barrier precautions to prevent skin and mucous membrane exposure when contact with blood or other body fluids of any patient is anticipated. Gloves should be worn for touching blood and body fluids, mucous membranes, or nonintact skin of all patients; for handling items or surfaces soiled with blood or body fluids; and for performing venipuncture and other vascular access procedures. Gloves should be changed after contact with each patient. Masks and protective eyewear or face shields should be worn during procedures that are likely to generate droplets of blood or other body fluids, to prevent exposure of mucous membranes of the mouth, nose, and eyes. Gowns or aprons should be worn during procedures that are likely to generate splashes or a spray of blood or other body fluids.
2. The hands and other skin surfaces should be washed immediately and thoroughly if they become contaminated with blood or other body fluids. The hands should be washed immediately after removing gloves.
3. All health care workers should take precautions to prevent injuries caused by needles, scalpels, and other sharp instruments or devices during procedures, when cleaning used instruments, during disposal of used needles, and when handling sharp instruments after procedures. Needles should not be recapped, purposely bent or broken by hand, removed from disposable syringes, or otherwise manipulated by hand. After use, disposable syringes and needles, scalpel blades, and other sharp items should be placed in puncture-resistant containers for disposal. The containers should be located as close as practical to the area where these items are used. Large-bore reusable needles should be placed in a puncture-resistant container for transport to the processing area.
4. Saliva has not been implicated in the transmission of the human immunodeficiency virus (HIV). However, to minimize the need for emergency mouth-to-mouth resuscitation, mouthpieces, resuscitation bags, or other ventilation devices should be available for use in areas where the need for resuscitation is predictable.
5. Health care workers with exudative lesions or weeping dermatitis should refrain from all direct patient care and from handling patient care equipment until the condition resolves.
6. Pregnant health care workers are not known to be at greater risk of contracting HIV infection than health care workers who are not pregnant. However, if a health care worker becomes infected with HIV during pregnancy, the infant is at risk of infection as a result of perinatal transmission. Because of this risk, pregnant health care workers should be especially familiar with and strictly follow precautions for minimizing the risk of HIV transmission.

Implementation of universal precautions for all patients eliminates the need for the isolation category of blood and body fluid precautions, which previously was recommended by the CDC for patients known to be or suspected of being infected with blood-borne pathogens. Isolation precautions (e.g., against enteric, acid-fast bacillus [AFB]) should be used as necessary if associated conditions such as infectious diarrhea or tuberculosis are diagnosed or suspected.

Standard precautions should not be confused with universal precautions. Standard precautions combine the major features of universal precautions (UP) and body substance isolation (BSI) and are based on the principle that all blood, body fluids, secretions, excretions except sweat, nonintact skin, and mucous membranes may contain transmissible infectious agents.

Standard precautions include a group of infection prevention practices that apply to all patients, regardless of suspected or confirmed infection status, in any setting in which health care is delivered. These include hand hygiene; use of gloves, gown, mask, eye protection, or face shield, depending on the anticipated exposure; and safe injection practices. Also, equipment or items in the patient's environment likely to have been contaminated with infectious body fluids must be handled in a manner to prevent transmission of infectious agents (e.g., wear gloves for direct

contact, contain heavily soiled equipment, properly clean and disinfect or sterilize reusable equipment before use on another patient).

The application of standard precautions during patient care is determined by the nature of the health care worker–patient interaction and the extent of anticipated exposure to blood, body fluids, or pathogens. For some interactions (e.g., performing venipuncture), only gloves may be needed; during other interactions (e.g., intubation), use of gloves, gown, and face shield or mask and goggles is necessary. Education and training in the principles and rationale for recommended practices are critical elements of standard precautions, because they facilitate appropriate decision making and promote adherence when the health care worker is faced with new circumstances. An example of the importance of the use of standard precautions is intubation, especially under emergency circumstances in which infectious agents may not be suspected but later are identified (e.g., severe acute respiratory syndrome coronavirus [SARS-CoV], *Neisseria meningitidis*). Standard precautions also are intended to protect patients by ensuring that health care personnel do not carry infectious agents to patients on their hands or on equipment used during patient care.

PART FOUR

Airway

Chapter 15: Airway Management, Respiration, and Artificial Ventilation

CHAPTER

15 Airway Management, Respiration, and Artificial Ventilation

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the anatomy of the airway and respiratory structures.
2. Distinguish between respiration, pulmonary ventilation, and external and internal respiration.
3. Explain the mechanics of ventilation and respiration.
4. Explain the relationship between partial pressures of gases in the blood and lungs to atmospheric gas pressures.
5. Describe pulmonary circulation.
6. Explain the process of exchange and transport of gases in the body.
7. Describe voluntary, nervous, and chemical regulation of respiration.
8. Discuss the assessment and management of airway obstruction.
9. Describe risk factors and preventive measures for pulmonary aspiration.
10. Outline the assessment of airway and breathing.
11. Describe the indications, contraindications, and techniques for delivering supplemental oxygen.
12. Discuss the methods of patient ventilation based on the indications, contraindications, potential complications, and use of each method.
13. Describe the use of manual airway maneuvers and mechanical airway adjuncts based on the indications, contraindications, potential complications, and techniques for each.
14. Describe effective techniques for verifying proper placement of endotracheal and peritracheal airway devices.
15. Explain variations in the assessment and management of airway and ventilation problems in pediatric patients.
16. Given a patient scenario, identify possible changes in oxygenation and ventilation and the appropriate interventions for treating those changes.

KEY TERMS

accessory muscles Muscles that sometimes assist in breathing; they include the scalenes and the sternocleidomastoid (deep muscles of the neck and thorax), posterior neck and back muscles, and abdominal muscles.

alveoli Small outpouchings of walls of alveolar space through which gas exchange takes place between alveolar air and pulmonary capillary blood.

anatomical dead space The volume of the conducting airways from the external environment down to the terminal bronchioles.

apneustic center A group of neurons in the pons that has a stimulatory effect on the inspiratory center.

atelectasis An abnormal condition characterized by the collapse of lung tissue; it prevents respiratory exchange of oxygen and carbon dioxide.

atmospheric pressure The pressure of the gas around us, which varies with differences in altitude. At sea level, it is 760 mm Hg.

biphasic positive airway pressure (BiPAP) Airway support that combines partial ventilatory support and continuous positive airway pressure; it allows the pressure to vary during each breath cycle.

Bohr effect The property of hemoglobin by which an increasing concentration of protons and/or carbon dioxide reduces the oxygen affinity for hemoglobin.

Boyle's law The principle of gas activity that states that gas flows from an area of higher pressure or concentration to an area of lower pressure or concentration; also known as the general gas law.

capnography The measurement of carbon dioxide concentrations in exhaled air; sometimes referred to as $etCO_2$ and $PetCO_2$.

carina of the trachea A downward and backward projection of the lowest tracheal cartilage; it forms a ridge between the openings of the right and left primary bronchi.

compliance The ease with which the lungs and thorax expand during pressure changes. The greater the compliance, the easier the expansion.

continuous positive airway pressure (CPAP) Airway support that transmits positive pressure into the airways of a spontaneously breathing patient throughout the respiratory cycle.

diaphragm The dome-shaped, musculofibrous partition that separates the thoracic and abdominal cavities.

diffusion The process by which solid, particulate matter in a fluid moves from an area of higher concentration to an area of lower concentration, resulting in an even distribution of the particles in the fluid.

expiratory reserve volume The amount of gas that can be forcefully exhaled after expiration of the normal tidal volume.

expiration Breathing out (exhalation), normally a passive process.

external respiration The transfer (diffusion) of oxygen and carbon dioxide between the inspired air and pulmonary capillaries.

extubation Removal of an endotracheal tube.

Fick principle The assumption that the amount of oxygen delivered to an organ is equal to the amount of oxygen consumed by that organ plus the amount of oxygen carried away from that organ. This principle is used to determine cardiac output.

gag reflex A normal neural response triggered by touching the soft palate or posterior pharynx.

Hering-Breuer reflex A reflex in which afferent impulses from stretch receptors in the lungs arrest inspiration; expiration then occurs; inflation and deflation reflexes are triggered to prevent overinflation of the lungs.

hypocarbia A state of diminished carbon dioxide in the blood; also called *hypocapnia*.

hypoxemia A state of decreased oxygen content of arterial blood.

hypoxia A state of decreased oxygen content at the tissue level.

hypoxic drive The low arterial oxygen pressure stimulus to respiration that is mediated through the carotid bodies.

inadvertent hyperventilation Excessive ventilation that is thought to result in increased intrathoracic pressure and decreased coronary perfusion pressure; also known as rescuer hyperventilation.

inspiration The act of drawing air into the lungs.

inspiratory reserve volume The maximum volume of air that can be inspired after a normal inspiration.

intercostal muscles Internal and external muscles between the ribs that contract to raise the ribs, thereby increasing the front-to-back (anterior-posterior) and side-to-side dimensions of the chest cavity.

internal respiration The transfer (diffusion) of oxygen and carbon dioxide between the capillary red blood cells and the tissue cells.

intrapulmonic pressure The pressure of the gas in the alveoli.

intrathoracic pressure The pressure in the pleural space; also known as the *intrapleural pressure*.

jugular notch The superior margin of the manubrium palpated easily at the anterior base of the neck; also known as the *suprasternal notch*.

left mainstem bronchus One of two main bronchi that branch from the trachea at the level of the carina.

lobules Small lobes or subdivisions of a lobe.

lower airway Airway structures below the glottis.

mediastinum A portion of the thoracic cavity in the middle of the thorax between the pleural sacs containing the two lungs; it extends from the sternum to the vertebral column and contains all the thoracic viscera except the lungs.

minute volume The amount of gas inhaled or exhaled in 1 minute. It is found by multiplying the tidal volume by the respiratory rate.

oxyhemoglobin Oxygenated hemoglobin.

partial pressure The pressure exerted by a single gas.

phrenic nerve A nerve composed mostly of motor nerve fibers that produce contractions of the diaphragm; also provides sensory innervation for many components of the mediastinum and pleura.

physiological dead space The sum of the anatomical dead space plus the volume of any nonfunctional alveoli.

pneumotaxic center A group of neurons in the pons that have an inhibitory effect on the inspiratory center.

positive end-expiratory pressure (PEEP) Airway support that maintains a degree of positive pressure at the end of exhalation.

pressure gradient The force produced by differences between atmospheric pressure, intrapulmonic pressure, and intrathoracic pressure.

pulmonary surfactant Certain lipoproteins that reduce the surface tension of pulmonary fluids, allowing the exchange of gases in the alveoli of the lungs and contributing to the elasticity of pulmonary tissue.

pulmonary ventilation The movement of air into and out of the lungs. This process brings oxygen into the lungs and removes carbon dioxide.

pulsus paradoxus An abnormal decrease in systolic blood pressure in which it drops more than 10 to 15 mm Hg during inspiration compared with expiration.

residual volume The volume of air remaining in the lungs after a maximum expiratory effort.

respiration The exchange of oxygen and carbon dioxide between an organism and the environment.

respiratory membrane The membrane in the lungs across which gas exchange with the blood occurs.

right mainstem bronchus One of two main bronchi that branch from the trachea at the level of the carina.

secondary bronchi Branches from a primary bronchus that conduct air to each lobe of the lungs.

surfactant Lipoproteins that reduce the surface tension of pulmonary fluids.

terminal bronchioles The ends of the conducting airways.

tidal volume The volume of air inspired or expired in a single, resting breath.

torr A measurement in millimeters of mercury.
total pressure The combination of pressures exerted by all the gases in any mixture of gas.
upper airway Airway structures above the glottis.
sternal angle The point at which the manubrium joins the body of the sternum; also known as the angle of Louis.
vallecula A furrow between the glossoepiglottic folds on each side of the posterior oropharynx.
ventilation The mechanical movement of air into and out of the lungs that makes respiration possible.
vocal cords The two folds of elastic ligaments covered by mucous membrane that stretch from the thyroid cartilage to the arytenoid cartilage; vibration of the vocal cords is responsible for voice production; also known as the true vocal cords.

An inadequate airway coupled with ineffective ventilation is a major cause of preventable death and cardiopulmonary complications in both medical and trauma patients. A thorough understanding of the respiratory system and mastery of airway management and ventilation are essential aspects of prehospital emergency care.

SECTION ONE
The Airway

AIRWAY ANATOMY

Successful management of the airway requires an understanding of the upper and lower airway structures and functions. For the purpose of this text, all airway structures above the glottis are considered the **upper airway**. All structures below the glottis are considered the **lower airway** (Box 15-1 and Figure 15-1). Airway anatomy was presented in Chapter 10; the following discussion serves as a review.

BOX 15-1 Structures of the Upper and Lower Airways

Upper Airway Structures
Nasopharynx
Frontal, maxillary, ethmoid, sphenoid sinuses
Oropharynx
Laryngopharynx
Larynx

Lower Airway Structures
Trachea
Bronchial tree
Alveoli
Lungs

(Courtesy Ray Kemp, St. Charles, Mo.)

Upper Airway

The human airway has two openings, the nose and the mouth. Air passes through the nose into the nasopharynx. This is the superior part of the pharynx. Air passes through the mouth into the oropharynx. The nasopharynx ends and the oropharynx begins at the level of the uvula. The oropharynx extends to the level of the epiglottis. The laryngopharynx (also known as the *hypopharynx*) extends from the tip of the epiglottis to the glottis and esophagus. The laryngopharynx opens into the larynx, which lies in the anterior neck (Figure 15-2).

NOTE
An important anatomical landmark in the laryngopharynx is the vallecula. The **vallecula** is a depression just behind the root of the tongue and between the folds of the throat. This area identifies where the curved blade of the laryngoscope is placed during endotracheal intubation to facilitate direct visualization of the glottis. (Endotracheal intubation is described later in this section.)

NOTE
When visualizing a patient's airway, remember that the floor of the nose is the roof of the mouth.

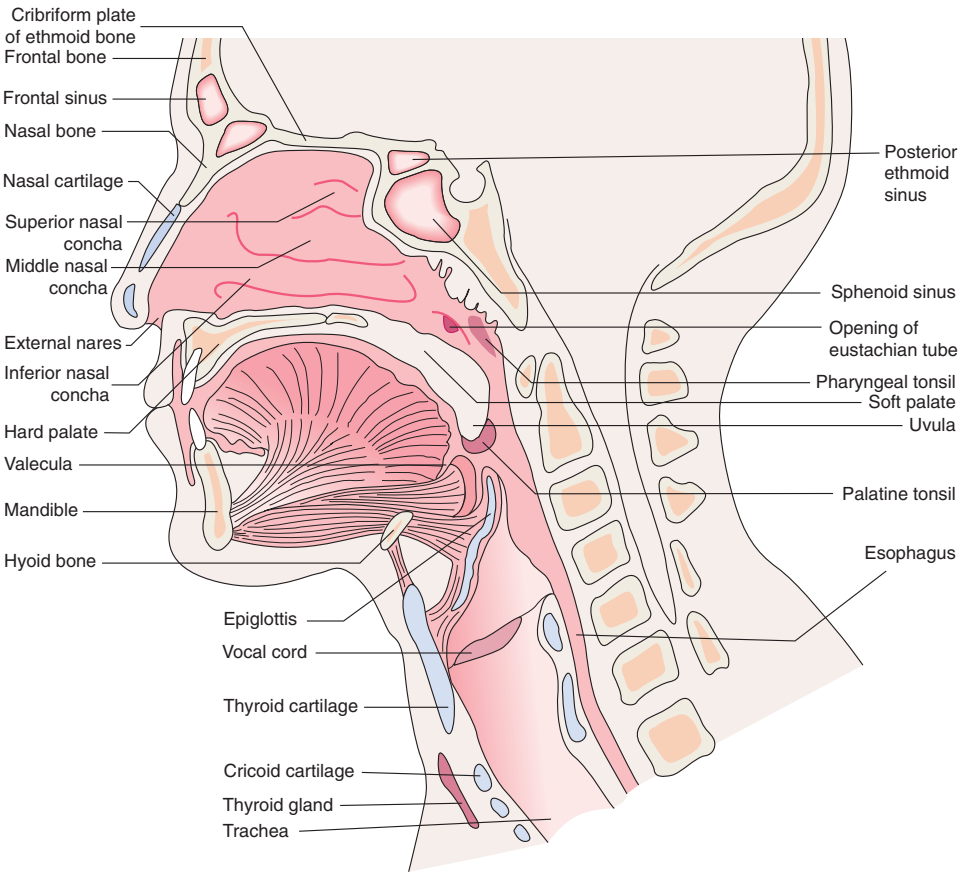

FIGURE 15-1 Midsagittal section through the upper airway. (From Wilkins RL, et al: *Egan's fundamentals of respiratory care,* ed 9, St Louis, 2009, Mosby.)

The larynx consists of an outer casing of nine cartilages. These cartilages are connected to each other by muscles and ligaments. Six of the nine cartilages are paired; three are unpaired. The unpaired thyroid cartilage is the largest, most superior of the cartilages. This structure is also known as the *Adam's apple.* The most inferior cartilage of the larynx is the unpaired cricoid cartilage. This cartilage is the only complete cartilage ring in the larynx. The third unpaired cartilage is the epiglottis. The six paired cartilages are stacked in two pillars between the cricoid cartilage and the thyroid cartilage. They are the *arytenoid cartilages,* the *corniculate cartilages,* and the *cuneiform cartilages.* The U-shaped hyoid bone is located beneath the mandible. The hyoid bone helps support the airway by anchoring muscles to the jaw. The thyroid membrane joins the hyoid bone and the thyroid cartilage. This fibrinous membrane is known as the *cricothyroid membrane.* The larynx also contains the true and false vocal cords. As described in Chapter 10, the **vocal cords** (Figure 15-3) regulate the flow of air to and from the lungs for the production of voice sounds. The endotracheal (ET) tube is passed through the open vocal cords of the larynx during endotracheal intubation. The larynx extends from the lower part of the pharynx to the trachea. On either side of the larynx is a recess called the *piriform sinus.* Foreign materials that are swallowed may become lodged in these areas.

Lower Airway

The trachea lies anterior to the esophagus. It is the air passage from the larynx to the lungs. The trachea begins at the border of the cricoid cartilage and ends where it bifurcates into the right and left main bronchi; this bifurcation is at the level of the **jugular notch**. The trachea is composed of 16 to 20 incomplete cartilaginous rings. These rings open posteriorly to prevent the trachea from collapsing.

The **carina of the trachea** is a downward and backward projection of the last tracheal cartilage. It forms a ridge that separates the opening of the **right mainstem bronchus** and the **left mainstem bronchus**. The carina occurs at the **sternal angle** (also known as the *angle of Louis*).

NOTE

The right main bronchus is wider, shorter, and more vertical than the left one. Because of this, the right main bronchus is the more common site of foreign body obstruction.

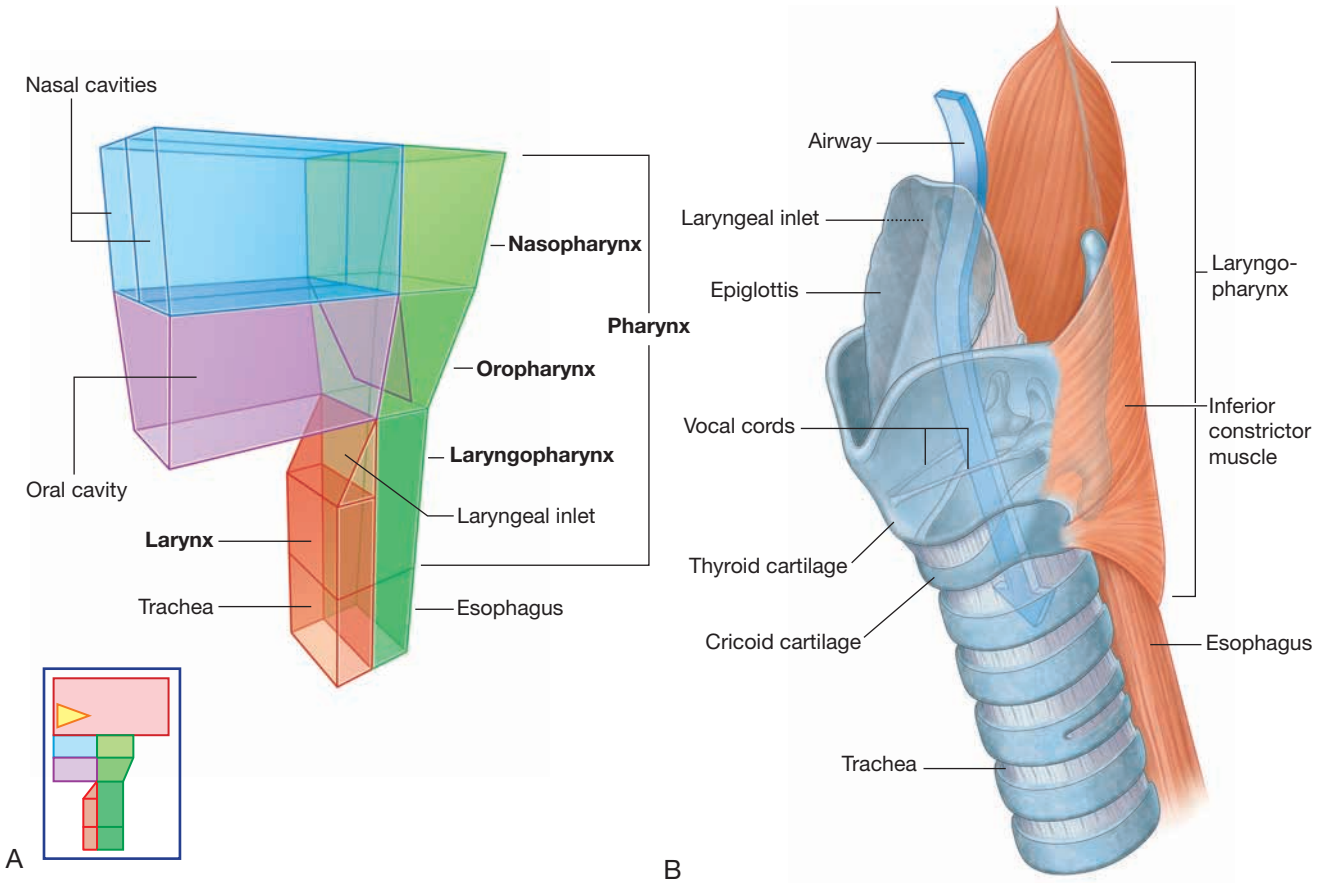

FIGURE 15-2 Specialized structures of the neck. **A,** Conceptual view. **B,** Anatomical view. (From Drake R: *Gray's anatomy for students,* ed 2, Philadelphia, 2010, Churchill Livingstone.)

The right and left main bronchi pass from the bifurcation of the trachea to the lungs to form the bronchial tree. The right and left main bronchi further branch into **secondary bronchi.** They divide again into tertiary segmental bronchi and finally **terminal bronchioles**. The terminal bronchioles are the smallest airways without alveoli. The terminal bronchioles divide into respiratory bronchioles and then alveolar ducts (Figure 15-4).

NOTE

Like the trachea, the bronchi are supported by cartilaginous rings. As the bronchi branch into smaller subdivisions, the amount of cartilage decreases and the bronchi become increasingly muscular. This continues until no cartilage is present. Bronchial smooth muscle has beta$_2$ adrenergic receptors. Therefore, the muscles are sensitive to certain hormones (e.g., epinephrine). The muscles also are sensitive to beta$_2$ receptor drugs such as albuterol. Stimulation of the beta$_2$ adrenergic receptors causes the bronchial smooth muscles to relax.

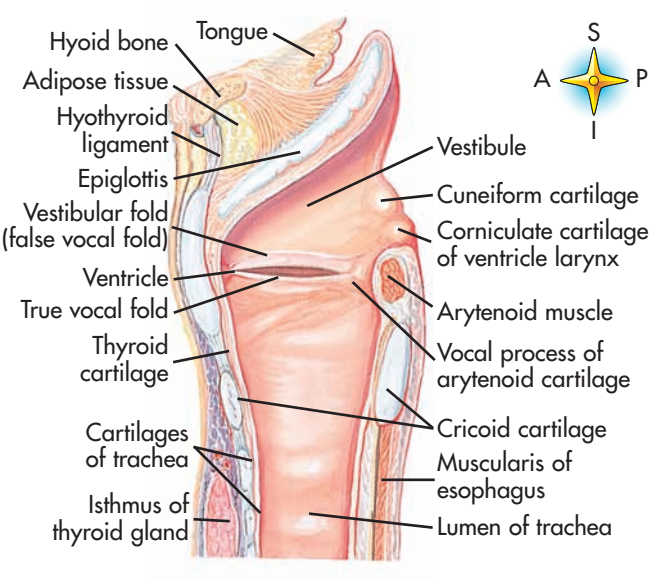

FIGURE 15-3 Vocal cords.

The **alveoli** are the functional units of the respiratory system. They make up most of the lung tissue. The alveoli also are where most of the respiratory gas exchange takes place. Together the two lungs have about 300 million alveoli.[1] Each alveolus is surrounded by a fine network of blood capillaries. The capillaries are arranged so that air in the alveolus is separated from the blood by a thin **respiratory membrane**. The alveoli are coated with **pulmonary surfactant.** The surfactant is a thin film produced

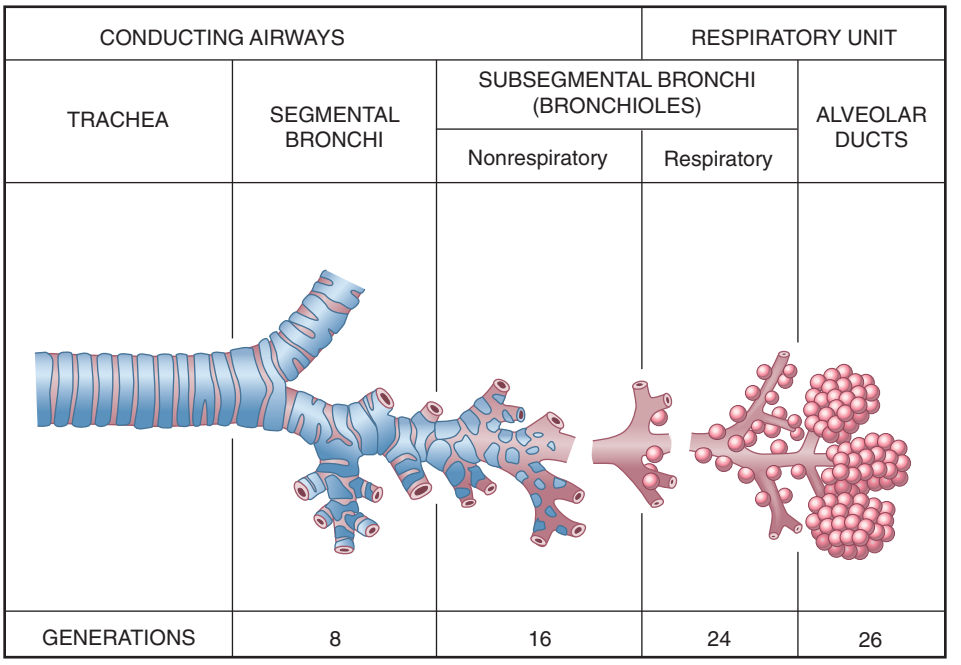

FIGURE 15-4 Structures of the lower airway (From McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2009, Mosby.)

by the alveolar cells that prevents the alveoli from collapsing.

The lungs are large, paired, spongy organs. They are attached to the heart by pulmonary arteries and veins. The two lungs are separated by the **mediastinum.** The contents of the mediastinum include the heart, blood vessels, trachea, esophagus, lymphatic tissue, and vessels. Each lung is shaped like a cone, with its base resting on the diaphragm. The left lung is smaller than the right and is divided into two lobes. The right lung has three lobes. Each lobe is divided into **lobules**. The left lung has nine lobules, and the right lung has 10 lobules. Both lungs are surrounded by a separate pleural cavity. The two layers of pleura are visceral and parietal. They are separated by a serous fluid. This fluid acts as a lubricant to allow the pleural membranes to slide past each other during breathing. The primary function of the lungs is **respiration** (the exchange of oxygen and carbon dioxide between an organism and the environment) (Figure 15-5).

NOTE

Respiration should not be confused with *ventilation*. **Ventilation** is the mechanical movement of air into and out of the lungs. Ventilation makes respiration possible.

SUPPORT STRUCTURES OF THE AIRWAY

The support structures of the airway include the thoracic cage, the phrenic nerve, and the mediastinum.

As described in Chapter 10, the thoracic cage protects vital organs. It also prevents collapse of the thorax during ventilation. The thoracic cage consists of the thoracic vertebrae, ribs and their associated costal cartilages, and the sternum (Figure 15-6). Muscles involved in ventilation include the **intercostal muscles** and the **diaphragm.** The intercostal muscles and accessory muscles (described later in this chapter) are used only during exercise, exertion, or distress. They are not used during quiet breathing. The diaphragm is the most important muscle for ventilation. When the diaphragm contracts, the abdominal contents are pushed downward and the intercostal muscles move the ribs upward and outward. This movement increases the volume and decreases the pressure in the thoracic cavity.

LOOK AGAIN

See Chapter 10: Review of Human Systems, pp. 158-162.

The **phrenic nerve** is composed mostly of motor nerve fibers. These motor nerve fibers produce contractions of the diaphragm. The phrenic nerve also provides sensory innervation for many components of the mediastinum and pleura. This is also true for the upper abdomen, especially the liver, and the gallbladder. The *right phrenic nerve* passes over the brachiocephalic artery, posterior to the subclavian vein, and then crosses the root of the right lung anteriorly. It leaves the thorax by passing through an opening in the diaphragm. The right phrenic nerve passes over the right atrium. The *left phrenic nerve* passes over the pericardium of the left ventricle and enters the diaphragm separately.

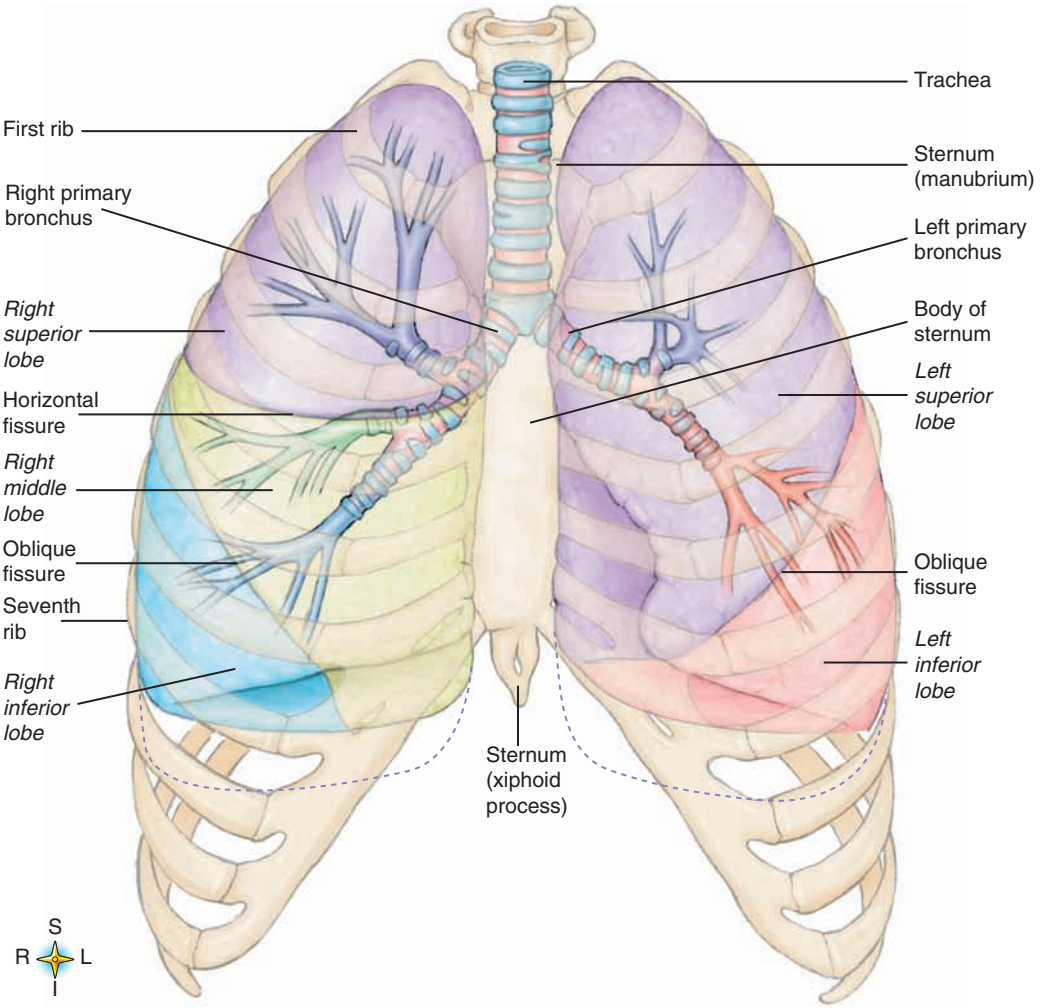

FIGURE 15-5 Lungs. The trachea is an airway that branches to form an inverted tree of bronchi and bronchioles. Note that the right lung has three lobes and the left lung has two lobes. (From Thibodeau GA, Patton KT: *Structure and function of the body,* ed 13, St Louis, 2008, Mosby.)

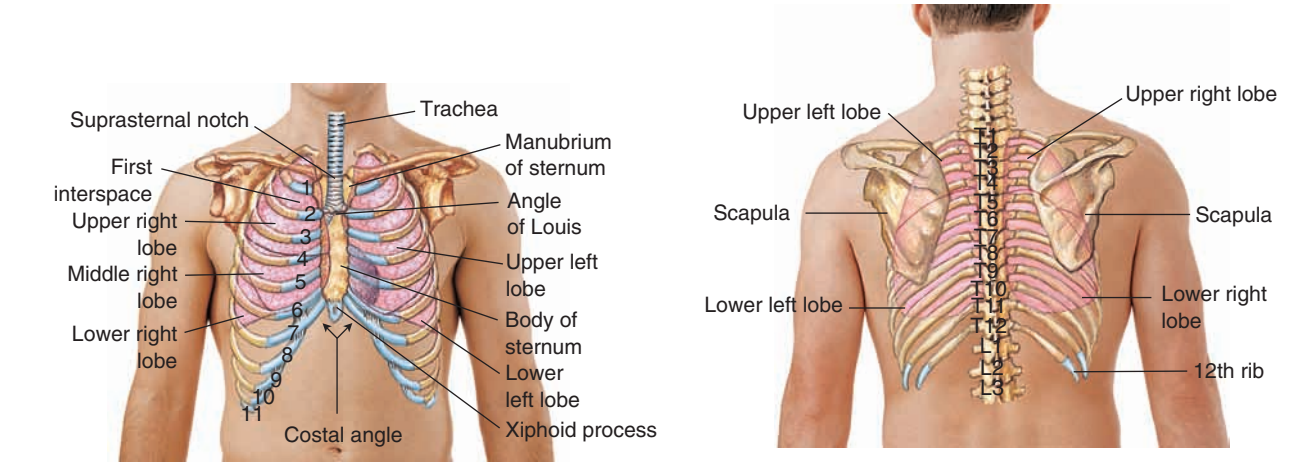

FIGURE 15-6 Thorax and underlying structures. **A,** Anterior view. **B,** Posterior view. (From Wilson SF, Giddens JF: *Health assessment for nursing practice,* ed 4, St Louis, 2009, Mosby.)

NOTE

The phrenic nerve originates from the spinal cord between cervical nerves C3 and C5. Injury to the spinal cord or brainstem may damage the nerve cells that stimulate the phrenic nerve, which facilitates contraction of the diaphragm (see Chapter 41).

As stated earlier, the contents of the mediastinum include the heart, blood vessels, trachea, esophagus, lymphatic tissue, and vessels. The mediastinum is the central compartment of the thoracic cavity and therefore is a supporting structure of the respiratory system. It lies between the right and left pleura in and near the median sagittal plane of the chest. It extends from the sternum in front to the vertebral column behind. It is continuous with the loose connective tissue of the neck, and extends inferiorly onto the diaphragm. The mediastinum contains all the thoracic viscera except the lungs (Figure 15-7).

SECTION TWO
Respiratory Physiology

MECHANICS OF RESPIRATION

As described previously, *respiration* is the exchange of oxygen and carbon dioxide between an organism and the environment. Oxygen is an essential nutrient for a living organism to produce energy. Carbon dioxide is a byproduct of energy production that must be removed from the body. For this gas exchange to occur, air must move freely into and out of the lungs. This brings oxygen into the lungs and removes carbon dioxide. This *mechanical process* is known as **pulmonary ventilation.**

The two phases of respiration are external respiration and internal respiration. **External respiration** is the transfer (diffusion) of oxygen and carbon dioxide between the inspired air and pulmonary capillaries. **Internal**

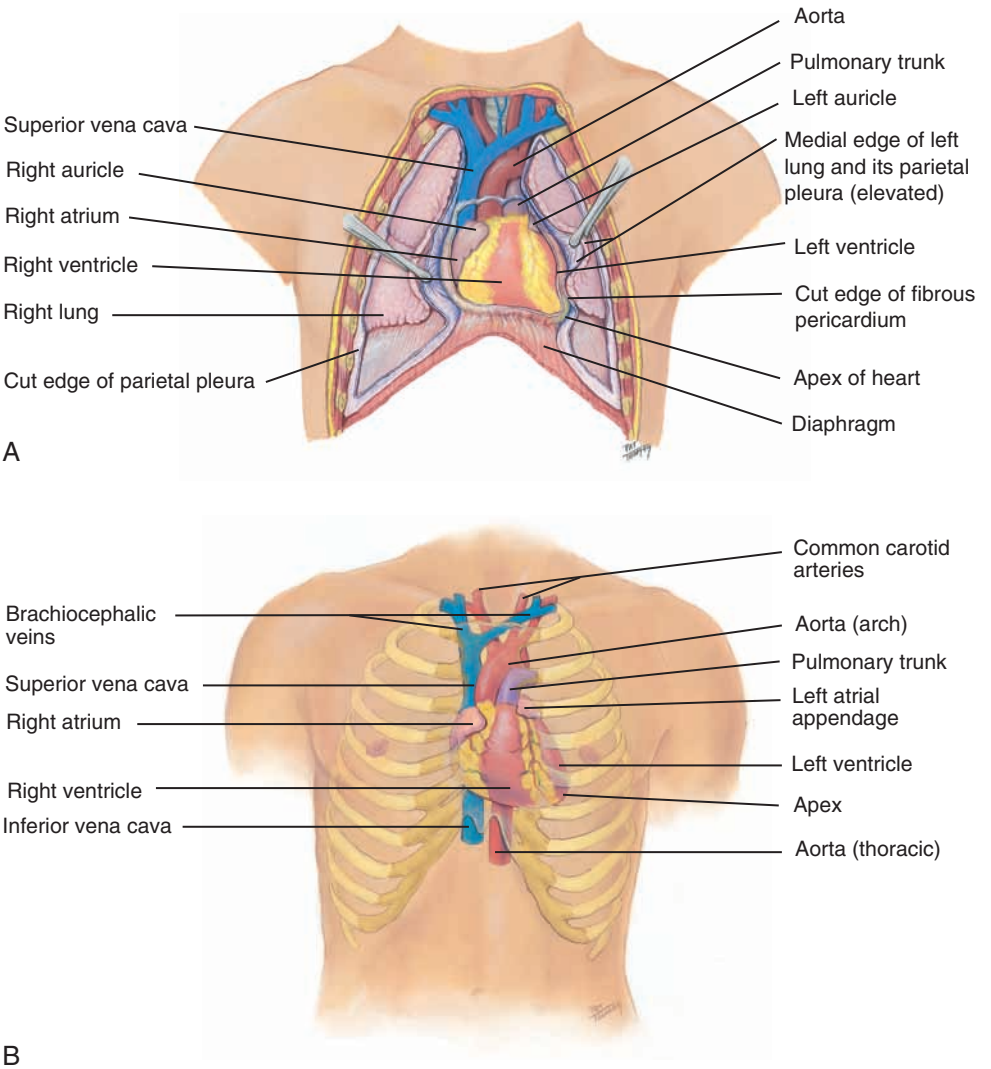

FIGURE 15-7 A, Frontal view of the mediastinum, showing the position of the heart **(B).** (Appelgate EM: *The anatomy and physiology learning system,* ed 3, St Louis, 2007, Saunders.)

respiration is the transfer (diffusion) of oxygen and carbon dioxide between the capillary red blood cells and the tissue cells.

Pressure Changes and Ventilation

Gas flows from an area of higher pressure or concentration to an area of lower pressure or concentration. For gas to flow into the lungs, a **pressure gradient** is required. This pressure gradient is produced by differences between atmospheric pressure, intrapulmonic pressure, and intrathoracic pressure (also known as *intrapleural pressure*).

CRITICAL THINKING
Think of two medical conditions that could impair (1) external respiration and (2) internal respiration.

Atmospheric pressure is the pressure of the gas around us. It varies with differences in altitude. At sea level, it is 760 mm Hg. **Intrapulmonic pressure** is the pressure of the gas in the alveoli. Depending on the size of the thorax, this pressure varies a little above and below 760 mm Hg. The intrapulmonic pressure also depends on whether it is measured during inspiration or expiration. **Intrathoracic pressure** is the pressure in the pleural space. It normally is less than the atmospheric pressure (usually 751 to 754 mm Hg). However, it may exceed the atmospheric pressure during coughing or straining during bowel movements.

During **inspiration** the chest wall expands. This increases the size of the thoracic cavity and expands the lungs. The expansion results from muscle movement and negative pressure in the pleural space. As the thorax expands, the lung space increases. This causes a drop in the intrapulmonic pressure of about 1 mm Hg below atmospheric pressure. The pressure gradient results in gas flow into the lungs. At end inspiration the thorax and alveoli stop expanding. The intrapulmonic pressure becomes equal to the atmospheric pressure, and gas no longer moves into the lungs (Figure 15-8).

As the chest wall relaxes during **expiration,** the muscles of ventilation are at rest. The process of inspiration reverses. Elastic recoil causes the thorax and lung space to decrease in size. This increases the intrapulmonic pressure. The pressure gradient created in the thoracic cavity produces a decrease in alveolar volume and increases the intrapulmonic pressure about 1 mm Hg over the atmospheric pressure. The pressure gradient results in gas flow out of the

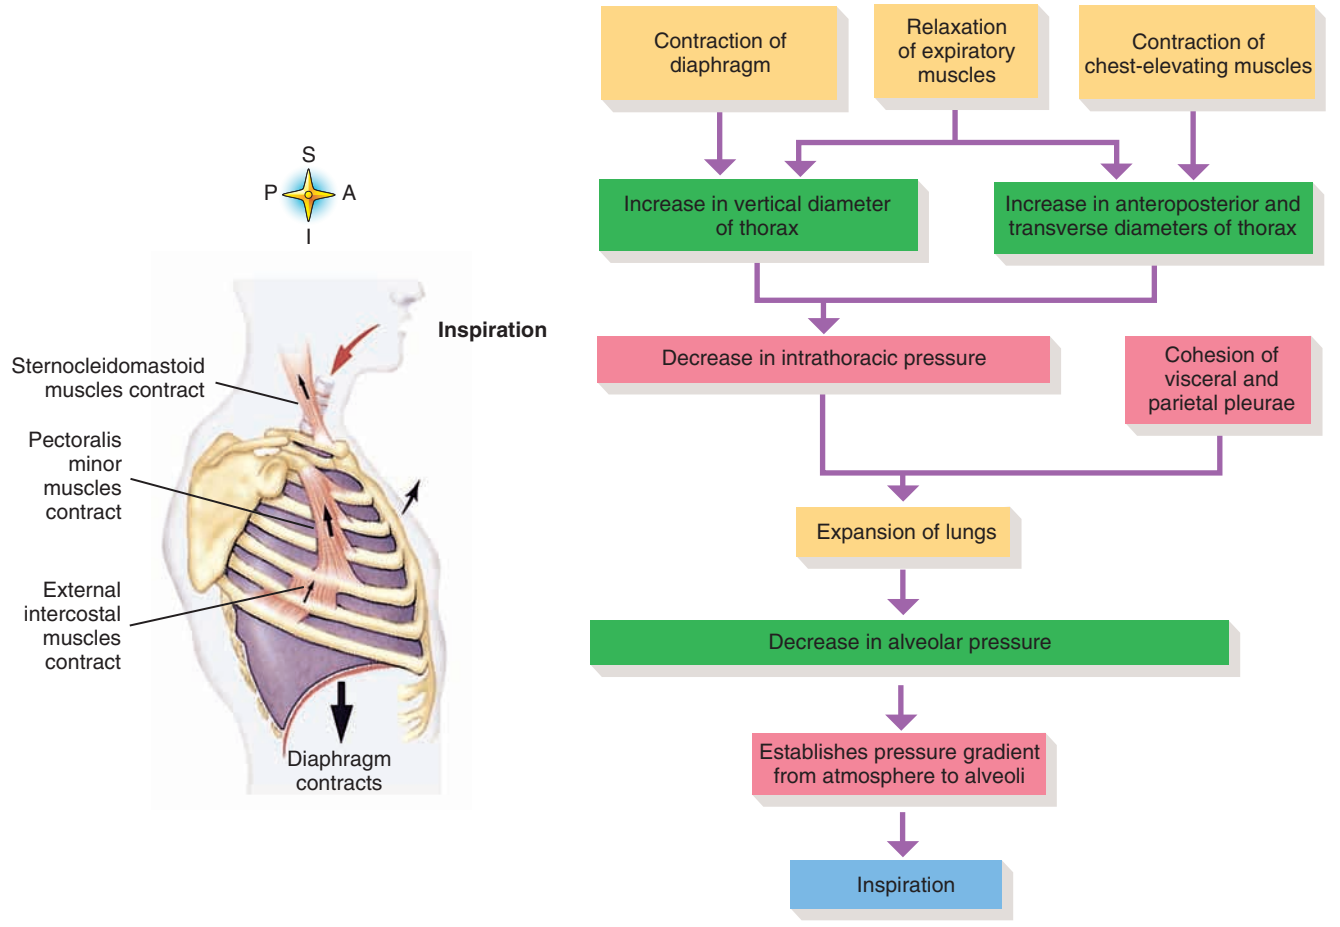

FIGURE 15-8 Mechanics of inspiration. (From Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

lungs. At the end of expiration the opposing forces and pressures become equal. The thoracic volume no longer decreases. The intrapulmonic pressure becomes equal to the atmospheric pressure, and gas movement out of the lungs stops (Figure 15-9).

NOTE

Boyle's law states that as a pressure of a gas decreases, its volume expands. Conversely, as a pressure of a gas increases, its volume decreases. (Pressure is inversely proportional to volume.) Simply put, during inspiration, when the thorax contracts, the volume in the chest increases, negative pressure occurs, and air enters the lungs. This process is reversed during expiration.

Muscles of Ventilation

Expansion of the lungs and thorax is caused by the movement of the diaphragm and the internal and external intercostal muscles (Figure 15-10). On inspiration, the diaphragm contracts and the dome of the diaphragm flattens. This increases the superior-inferior dimension of the chest cavity. The internal and external intercostal muscles also contract. This raises the ribs. It also increases the front-to-back (anterior-posterior) and side-to-side dimensions of the chest cavity.

CRITICAL THINKING

How does interruption of the chest wall from a stab wound change the mechanics of breathing?

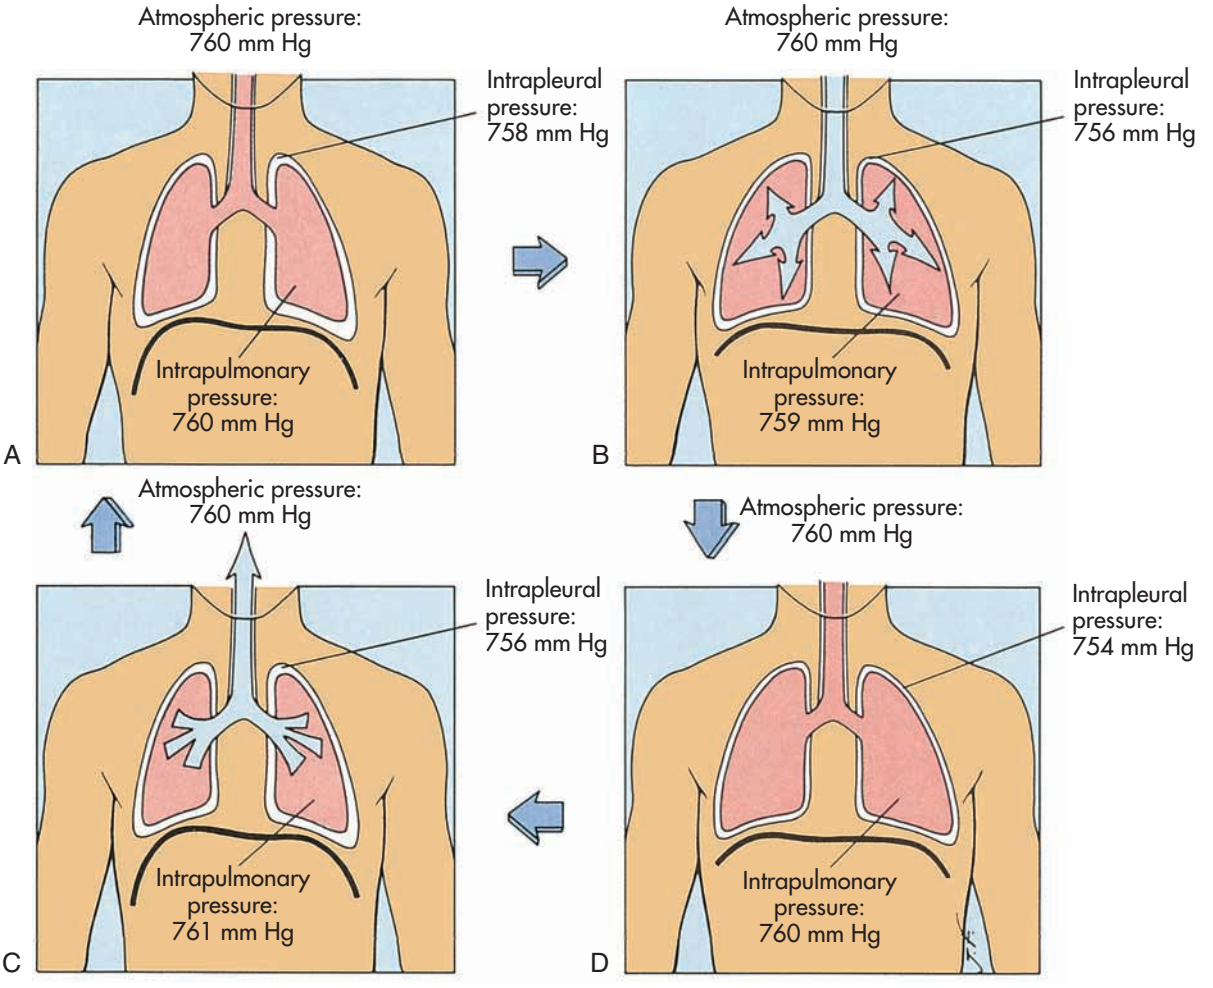

FIGURE 15-9 Pressure changes during inspiration and expiration. **A,** At the end of expiration, intrapulmonary pressure equals atmospheric pressure, and no movement of air occurs. **B,** During inspiration, the volume of the pleural space increases, causing the pressure in the intrapulmonary spaces (alveoli) to decrease. Air then flows from the outside of the body, where the pressure is greater (760 mm Hg), into the alveoli, where it is lower (759 mm Hg). **C,** At the end of inspiration, intrapulmonary pressure again equals atmospheric pressure, and no movement of air occurs. **D,** During expiration, the volume of the pleural spaces decreases, causing the intrapulmonary pressure to increase. Because the intrapulmonary pressure exceeds the atmospheric pressure, air flows out of the lungs.

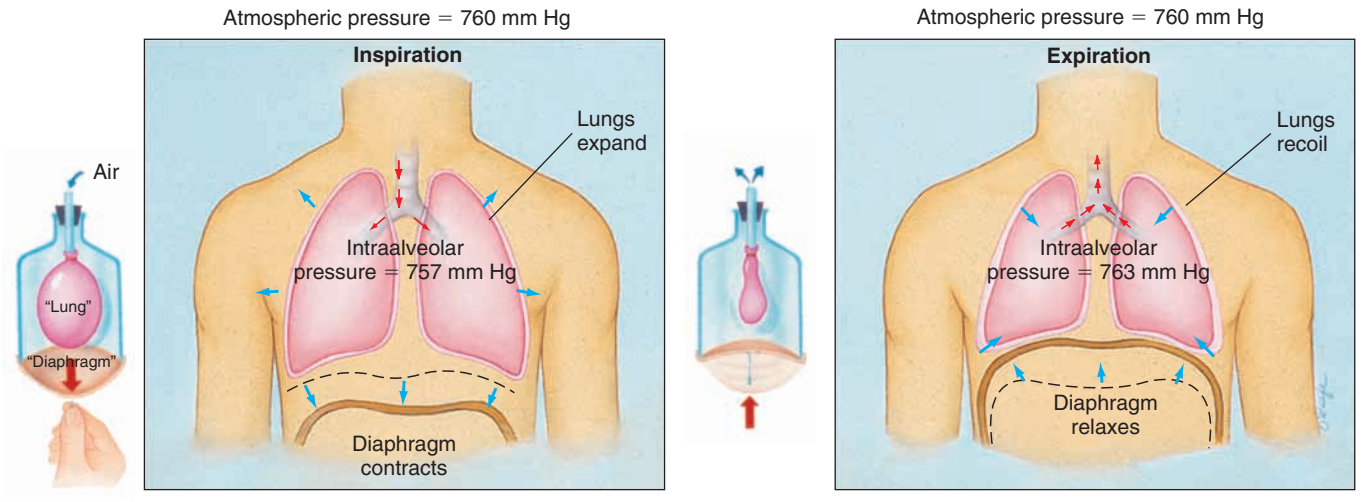

FIGURE 15-10 During inhalation, the diaphragm contracts, increasing the volume of the thoracic cavity. The increase in volume results in a decrease in pressure, which causes air to rush into the lungs. During expiration, the diaphragm returns to an upward position, reducing the volume of the thoracic cavity. Air pressure increases and forces air out of the lungs. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

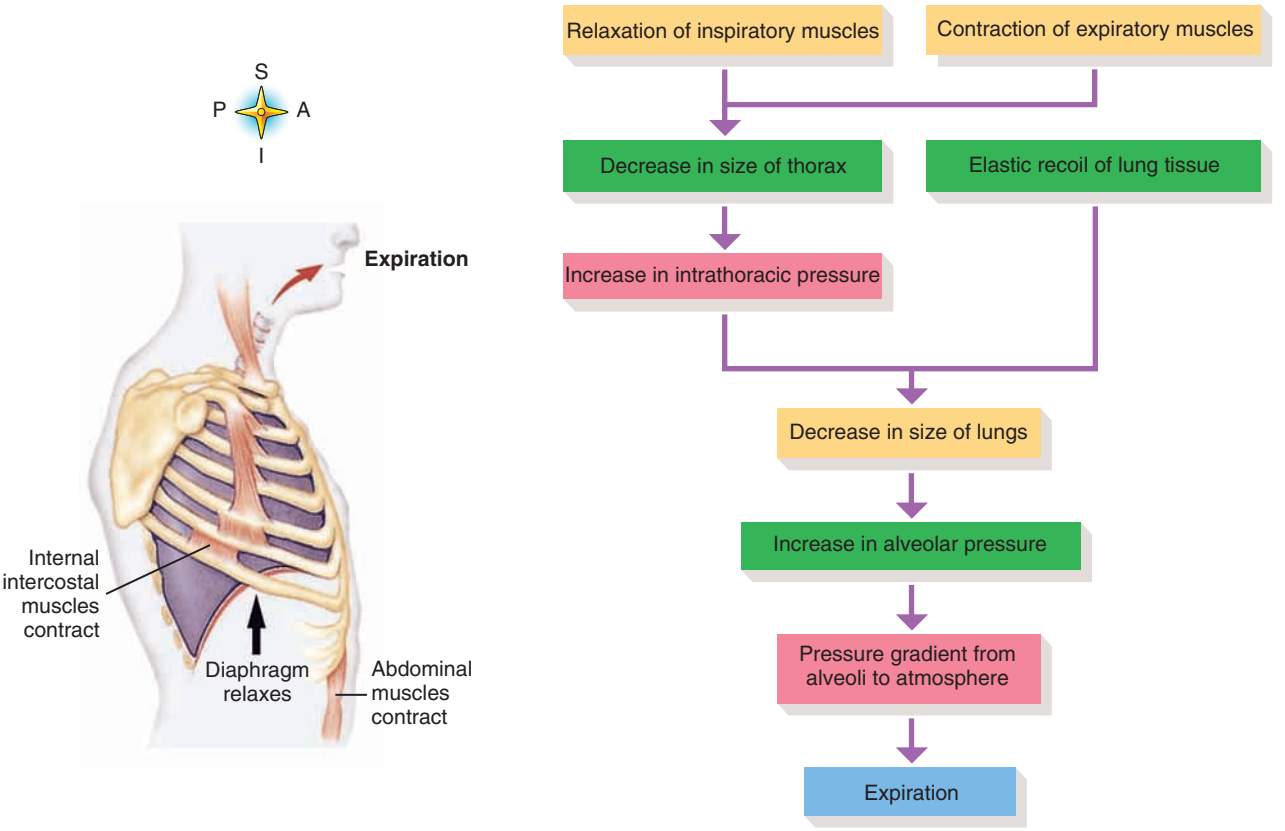

FIGURE 15-11 Relaxation of the diaphragm and contraction of the chest-depressing muscles (the internal intercostal muscles) reduce the thoracic volume. This increases pressure in the lungs, pushing air out. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

Expiration is a passive motion. During expiration, relaxation of the diaphragm and internal intercostal muscles allows the elastic recoil properties of the lungs to reduce the size (or volume) of the thoracic cavity (Figure 15-11). The ease with which the lungs and thorax expand during pressure changes is known as **compliance.** The greater the compliance, the easier the expansion. Diseases that reduce compliance increase the energy required for breathing. Examples of such diseases are asthma, bronchitis, and pulmonary edema. Other diseases, such as emphysema, increase

lung compliance by breaking down the elastic fibers that surround lung tissue. This may be the result of overstretching of the fibers from chronic coughing.[2,3] These patients have no problem inflating the lungs but have extreme difficulty exhaling air (see Chapter 24).

Work of Breathing

In people who are healthy, the energy needed for normal, quiet breathing is about 3% of the total body expenditure.[4] Factors that increase the amount of energy needed for ventilation include loss of pulmonary surfactant (e.g., from smoke inhalation), an increase in airway resistance (e.g., from asthma), or a decrease in pulmonary compliance (e.g., from cystic fibrosis). These factors can increase the energy requirement to as much as one third of the total body expenditure.[5]

The pulmonary alveoli have a tendency to collapse. This is the result of recoil caused by the elastic fibers and the surface tension of the alveolar walls. The surface tension is created because water molecules are attracted to each other in the alveolar membrane. Pulmonary surfactant lowers the surface tension. It does this by intermingling with the water molecules to reduce the cohesive force. This helps prevent collapse of the alveolus at the end of expiration.

NOTE

Atelectasis is the collapse (diminished volume) of all or part of the lung. This condition can be caused by obstruction, such as from a foreign body, tumor, or mucous plugging. It also may be caused by compression (e.g., pneumothorax). A deficiency in surfactant (e.g., decreased production or inactivation of surfactant) is another cause. Continuous positive airway pressure (CPAP), biphasic positive airway pressure (BiPAP), and positive end-expiratory pressure (PEEP) can prevent the collapse of alveoli. These airway therapies increase the amount of gas that remains in the lungs at the end of expiration. This prevents the collapse of alveoli and improves the ease and work of breathing in patients who have respiratory distress. (CPAP and PEEP are described later in this chapter and in Chapter 24.)

Surfactant is composed of lipoproteins that reduce the surface tension of pulmonary fluids. Surfactant is constantly being replenished by certain alveolar cells. Its production is thought to be stimulated by normal ventilation. If this production decreases, as occurs in pneumonia, very high ventilation pressures may be needed to produce lung expansion.

The elastic forces of the lung oppose lung expansion. Viscous and frictional forces often play the central role in impeding airflow into and out of the lungs. Much of the resistance to airflow is provided by the upper airways of the respiratory tract. The nasal passages cause about 50% of the total airway resistance during nose breathing. The mouth, pharynx, larynx, and trachea account for approximately 20% to 30% of airway resistance during quiet mouth breathing. This may increase to about 50% during times of increased ventilation (e.g., during vigorous exercise).[5]

Airway resistance falls greatly as the bronchial tree continues to branch toward the alveoli. Still, the presence of airway secretions or bronchiolar constriction can lead to increased airway resistance. These factors may occur separately. More often, they occur at the same time (e.g., as in asthma). When resistance to airflow increases, the usual pressure gradient needed for ventilation is inadequate. Therefore, muscular effort is needed to create a larger pressure gradient.

Structural changes in the lungs or thorax as a result of trauma or disease also may increase the amount of work needed for effective ventilation. This increased work usually is obvious from the use of **accessory muscles** during labored breathing. The accessory muscles include the scalenes and the sternocleidomastoid (deep muscles of the neck and thorax), posterior neck and back muscles, and the abdominal muscles (Figure 15-12).

Lung Volumes and Capacities

At rest, the average adult breathes about 12 to 24 times a minute. One fifth of this inspired air never reaches the alveoli for gas exchange. Instead, it fills the upper respiratory tract and lower nonrespiratory bronchioles.[6] This area is referred to as **anatomical dead space.** The term **physiological dead space** refers to the anatomical dead space plus the volume of any nonfunctional alveoli. Usually the anatomical and physiological dead spaces are nearly identical. However, this is not always the case. In patients with respiratory diseases, such as emphysema, the alveolar walls begin to degenerate. The destruction of these walls can increase the size of the physiological dead space up to 10 times that of the anatomical dead space (Figure 15-13).

The lungs can hold about eight times the amount of air brought in by a normal resting inhalation. From the first breath of life, the lungs are never fully emptied. Even after forced expiration, a "residual volume" of air remains in the alveoli. This residual volume is replenished slowly. At least 16 breaths, and at times more, are needed to renew the residual volume of air in the lungs.[7]

The **tidal volume** is the volume of gas inhaled or exhaled during a normal breath. The tidal volume of the average adult is about 500 to 600 mL. Of this, 150 mL remains in the anatomical dead space (the bronchi, bronchioles, and other prealveolar structures) until it is exhaled during the next respiratory cycle. Therefore, 150 mL of the atmospheric gas inhaled during each inspiration never reaches the alveoli. It is merely moved into and out of the airways. A paramedic observing the rise and fall of a patient's chest is indirectly observing tidal volume.

The **inspiratory reserve volume** is the amount of gas that can be forcefully inhaled after inspiration of the normal tidal volume. This amount is usually 2000 to 3000 mL. The **expiratory reserve volume** is the amount of

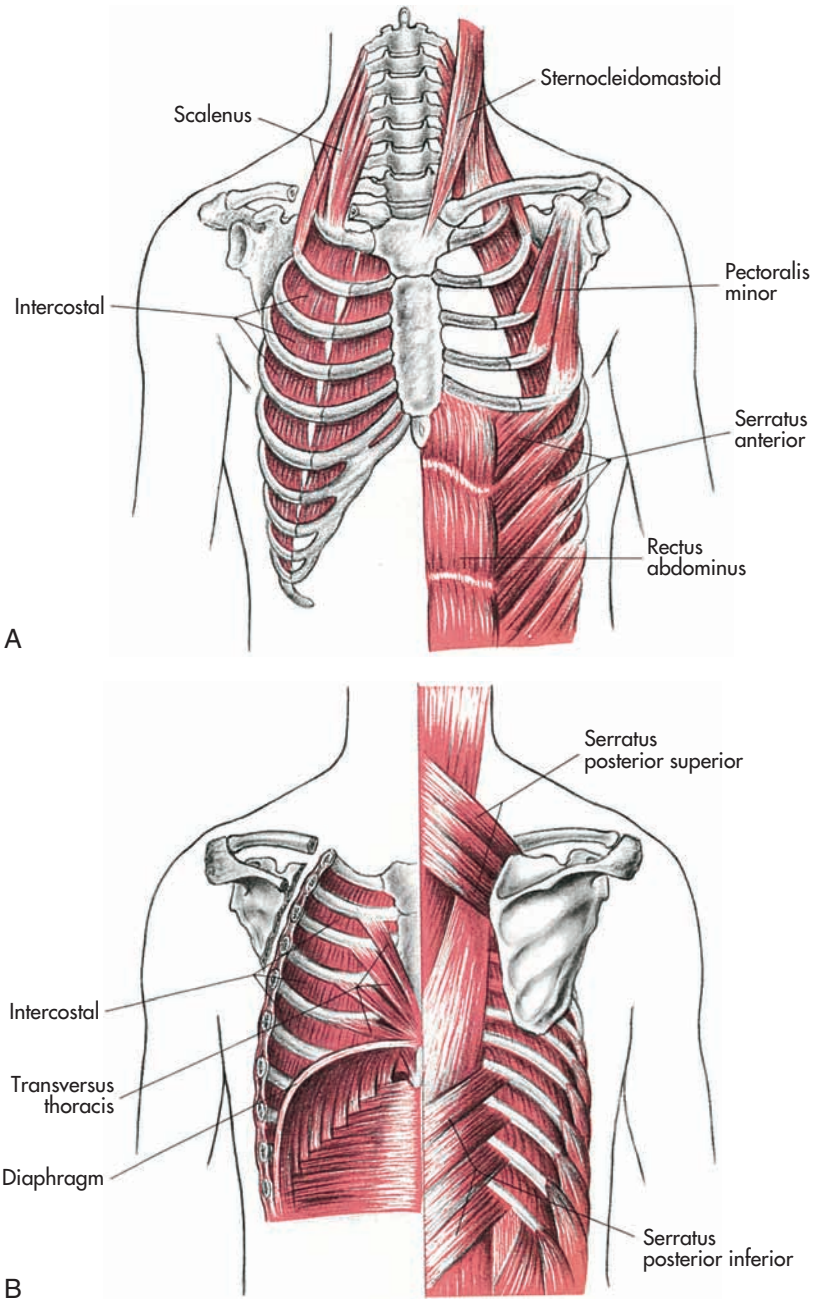

FIGURE 15-12 Muscles of ventilation. **A**, Anterior view. **B**, Posterior view. (From Seidel H et al: *Mosby's guide to physical examination,* ed 6, St Louis, 2007, Mosby.)

gas that can be forcefully exhaled after expiration of the normal tidal volume. This volume usually is less than the inspiratory reserve volume (about 1200 mL). The **residual volume** is the gas that remains in the respiratory system after forced expiration. The normal residual volume is 1000 to 1200 mL.

The combined measurements of tidal volume, inspiratory reserve volume, expiratory reserve volume, and residual volume constitute the maximum volume to which the lungs can be expanded.

Pulmonary capacities are the sum of two or more pulmonary volumes. The more common pulmonary capacities are as follows (Figure 15-14):

- *Inspiratory capacity*: Inspiratory capacity is the tidal volume plus the inspiratory reserve volume. This capacity reflects the amount of gas a person can inspire maximally after a normal expiration (about 3500 mL).
- *Functional residual capacity*: Functional residual capacity is the expiratory reserve volume plus the residual

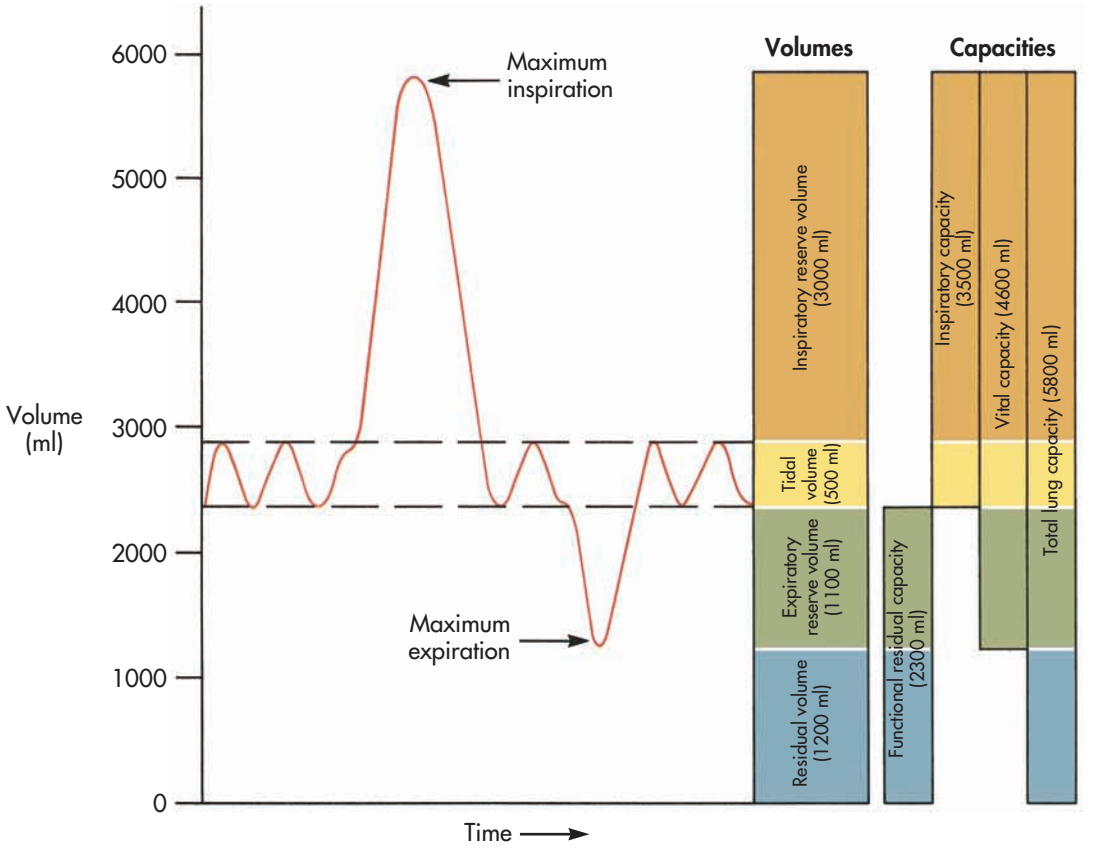

FIGURE 15-13 Lung volumes and capacities. Tidal volume during resting conditions. (From Seeley R: *Anatomy and physiology,* ed 2, St Louis, 1992, Mosby.)

Pulmonary Capacities	
Tidal volume + Inspiratory reserve volume	Expiratory reserve volume + Residual volume
Inspiratory capacity (3500 mL)	**Functional residual capacity (2300 mL)**
Inspiratory reserve volume Tidal volume + Expiratory reserve volume	Vital capacity + Residual volume
Vital capacity (4600 mL)	**Total lung capacity (5800 mL)**

FIGURE 15-14 Pulmonary capacities.

volume. This capacity reflects the amount of gas remaining in the lungs at the end of a normal expiration (about 2300 mL).

- *Vital capacity*: Vital capacity is the volume of gas that can move on deepest inspiration and expiration or the sum of the inspiratory reserve volume, the tidal volume, and the expiratory reserve volume. This capacity is about 4600 mL.
- *Total lung capacity*: Total lung capacity is the sum of the vital capacity and the residual volume (about 5800 mL).

CRITICAL THINKING

Consider a severe burn that encircles the chest. Which respiratory volumes are affected?

Minute Volume and Minute Alveolar Ventilation

The **minute volume** is the amount of gas inhaled or exhaled in 1 minute. It is found by multiplying the tidal volume by the respiratory rate. For example, a patient's respiratory rate may be 10 breaths per minute, and the resting tidal volume may be 500 mL. Thus the average minute volume is 5 L/min.

Much of the gas that is inspired during breathing fills the anatomical dead space before reaching the alveoli. That air therefore is unavailable for gas exchange. The amount of inspired gas available for gas exchange during 1 minute is referred to as the *minute alveolar ventilation.* The minute alveolar ventilation is calculated by subtracting the amount of dead space from the tidal volume and then multiplying the result by the respiratory rate:

Minute alveolar ventilation = (Tidal volume – Dead space) × Respiratory rate

If the tidal volume or the respiratory rate, or both, increase, the minute volume also increases. Likewise, if the tidal volume or the respiratory rate, or both, decrease, the minute volume decreases. The paramedic must note the depth of breathing (tidal volume) and the respiratory rate to determine whether the patient's respiratory status is adequate.

MEASUREMENT OF GASES

As described in Chapter 11, the mixture of gases that make up the atmosphere exerts a combined partial pressure. This pressure is measured in millimeters of mercury, or **torr** (1 torr = 1 mm Hg), based on the percentage of a particular gas (Table 15-1). The atmospheric pressure at sea level (760 mm Hg) represents 100%. Nitrogen makes up about 78.62% of the volume of dry atmospheric gas at sea level. The partial pressure that results from nitrogen is calculated by multiplying 78.62% by 760 mm Hg. This equals 597 mm Hg, or a partial pressure of nitrogen (P_{N_2}) of 597 torr. Oxygen accounts for 20.84% of the volume of atmospheric gas. The partial pressure of oxygen (P_{O_2}), therefore, is found by multiplying 20.84% by 760 mm Hg. This equals 159 mm Hg, or a P_{O_2} of 159 torr (Figure 15-15).

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, p. 216.

TABLE 15-1 Concentration of Gases

Gas	Concentration
Atmospheric Gases	
Nitrogen	597 torr (78.62%)
Oxygen	159 torr (20.84%)
Carbon dioxide	0.3 torr (0.50%)
Water (vapor)	3.7 torr (6.2%)
Alveolar Gases	
Nitrogen	569 torr (74.9%)
Oxygen	104 torr (13.7%)
Carbon dioxide	40 torr (5.2%)
Water (vapor)	47 torr (6.2%)

NOTE
To review: In any mixture of gases, the combination of the pressure exerted by all the gases is the **total pressure.** The pressure exerted by a single gas is the **partial pressure.** The partial pressure of a gas in a mixture is denoted by a *P* preceding the gas. For example, the partial pressure of oxygen is P_{O_2}. The partial pressure of carbon dioxide is P_{CO_2}.

Another partial pressure can be measured when gas comes into contact with water. The water molecules convert into a gas, evaporate, and exert a partial pressure. This partial pressure is known as *water vapor pressure* (PH_2O).

The compositions of alveolar gas and dry atmospheric gas are not the same. This is a result of several factors:

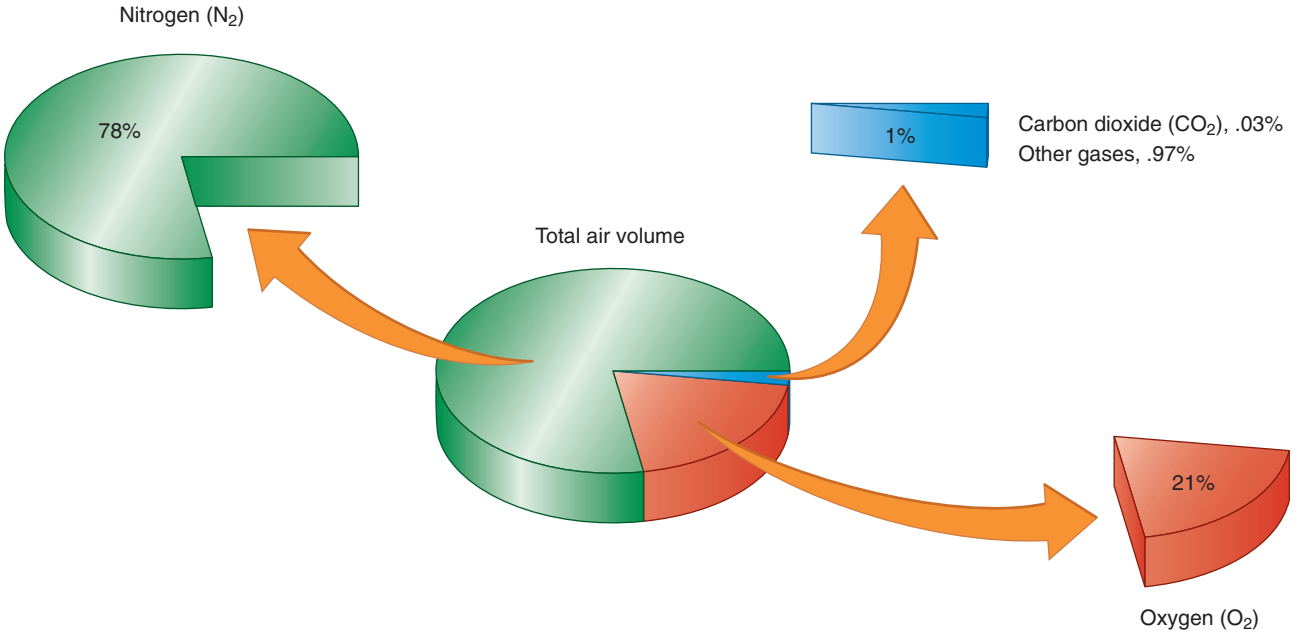

FIGURE 15-15 Partial pressure of gases in atmospheric air. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

humidification of the air entering the respiratory system by the body, the exchange of oxygen and carbon dioxide between the alveoli and the blood, and incomplete emptying of the alveoli with expiration.

PULMONARY CIRCULATION

The process of gas exchange in the lungs is the opposite of that which occurs in the tissues throughout the rest of the body. As inspired gas enters the lungs, the respiratory system brings oxygen to the blood and removes carbon dioxide. Blood that is low in oxygen returns to the heart from all parts of the body. Passing through the right side of the heart, the blood flows into either lung through the pulmonary artery. From there it flows into the smaller pulmonary arterioles. Then it flows into capillaries that surround each of the hundreds of millions of alveoli inside the lungs (Figure 15-16).

The alveoli are now filled with a high concentration of oxygen molecules and a low concentration of carbon dioxide molecules as a result of the inhaled air. They have the pressure gradient required for gas exchange. Oxygen molecules move into the surrounding capillaries at the same time that carbon dioxide molecules move into the alveoli to be exhaled. The blood is now rich in oxygen. It flows through the pulmonary venules into the pulmonary veins. From there it flows into the left atrium and then into the left ventricle. Next, it flows back out through the aorta to the body's tissues. To supply enough oxygen to the body tissues, an alveolus fills and empties more than 15,000 times in a day of normal breathing.[8]

Exchange and Transport of Gases in the Body

The volume of oxygen taken up in the lungs can be measured. It can be calculated from the difference in the amount of oxygen in inspired and expired air. The volume of carbon dioxide that is eliminated can be determined in a similar way.

As noted in Chapter 10, *metabolism* is defined as all the chemical changes that occur in the body. In a healthy body with a constant metabolism, the relationship between tissue carbon dioxide production and oxygen consumption is fixed. In general, the amount of oxygen taken up by the

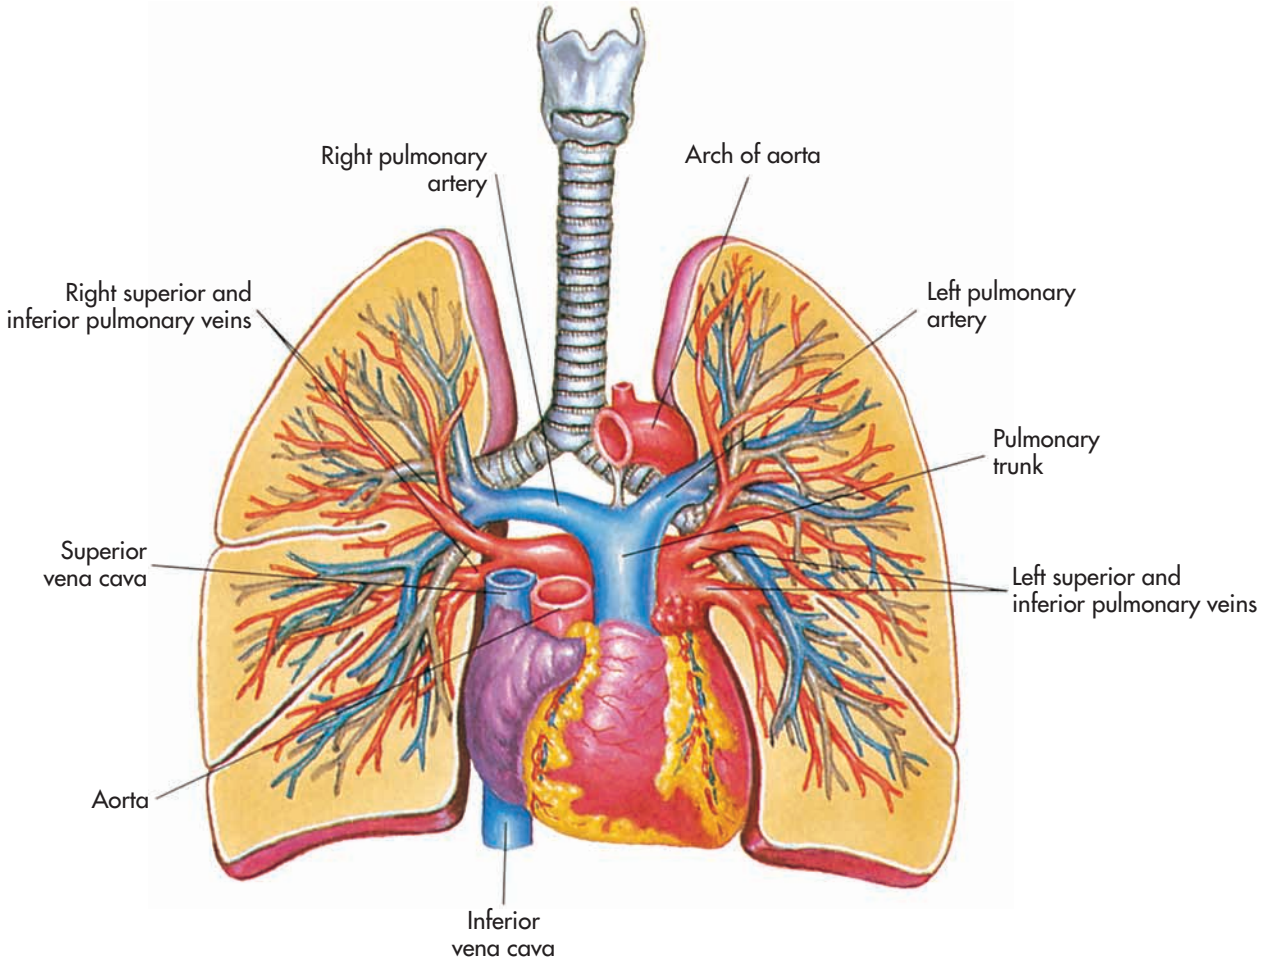

FIGURE 15-16 Pulmonary circulation. (Wilson S: *Respiratory disorders,* St Louis, 1990, Mosby.)

capillary blood is greater than the amount of carbon dioxide released by the blood to the alveolar gas. Thus the expired volume is slightly less than the inspired volume.

At rest, the combined consumption of all the body cells is about 200 mL of oxygen per minute. About the same amount of carbon dioxide is produced by the cells. Because about 20% of atmospheric gas is oxygen, the total oxygen inspired is 20% multiplied by 5 L, or about 1 L of oxygen per minute. Of this, 200 mL crosses the alveoli into the pulmonary capillaries. The remaining 800 mL is exhaled. The 200 mL of oxygen is added to the quantity of oxygen already in the pulmonary capillaries. It is then transported to body tissues by the circulatory system. After the body cells use the necessary oxygen, the oxygen remaining in the blood returns to the heart and lungs. This exchange of oxygen and carbon dioxide is carried out by the passive process of diffusion. As described in Chapter 11, **diffusion** is the tendency for molecules in solution to move from an area of higher concentration to an area of lower concentration.

LOOK AGAIN

See Chapter 11: General Principles of Pathophysiology, pp. 217-218

Diffusion

Molecules of gases are in constant, random motion. This motion is fueled by collisions with other molecules. If the blood is divided by a permeable barrier, such as a capillary wall or cell membrane, many gas molecules come in contact with and cross the barrier. The likelihood is much greater that highly concentrated molecules will strike and cross the membrane than less concentrated molecules. Thus the concentration of molecules on either side of a permeable membrane tends to equilibrate (Figure 15-17).

The diffusion of gases through liquid is determined by the pressure of the gases. It also is determined by the solubility of the gases in liquid (Figure 15-18). When a free gas comes into contact with liquid, the number of gas molecules that dissolve in the liquid is directly proportional to the pressure of the gas. When the free gas pressure is higher than the pressure of the gas in the liquid, enough molecules dissolve in the liquid to allow the free gas pressure to equal the dissolved gas pressure.

On the other hand, if a liquid containing a dissolved gas at a high pressure is exposed to a free gas at a lower pressure, gas molecules leave the liquid and enter the free gas until the pressures become equal (the *general gas law*). This is the underlying theme of the exchange of gases between the cells and the capillary blood throughout the body. The partial pressure of the free gas (P_{O_2}) in the lungs is greater than the partial pressure of the dissolved oxygen in the bloodstream. Thus oxygen diffuses from the lungs to the blood. The partial pressure of oxygen in the blood is higher than that in the peripheral tissues. Thus oxygen diffuses from the blood into the tissues.

In addition to its pressure, the solubility of a gas also is a factor. The solubility of gases in a liquid affects the behavior of the gases. The ease with which gases dissolve determines the absolute number of gas molecules that diffuse through the liquid at a given pressure. For example, a liquid may be exposed to two different gases at the same pressure. The number of molecules of each gas that diffuse may not be the same because of the differing solubilities of the two gases.

Blood entering the pulmonary capillaries is systemic venous blood that has been circulated to the lungs via the pulmonary arteries. The partial pressure of carbon dioxide (P_{CO_2}) is relatively high in this blood; the partial pressure of oxygen (P_{O_2}) is low. The alveoli have a greater concentration of oxygen than the blood entering the pulmonary capillaries. Thus oxygen molecules diffuse from the alveoli into

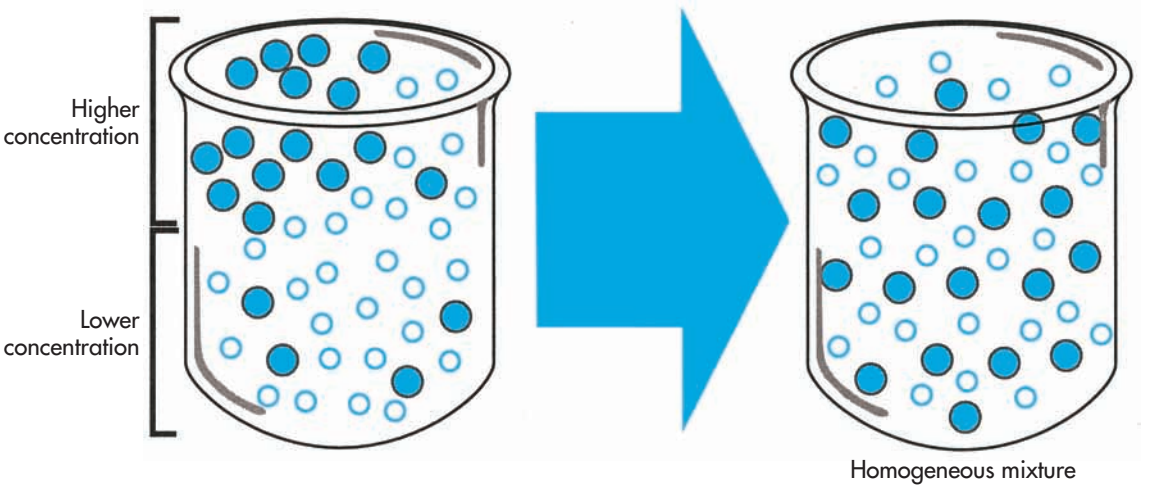

FIGURE 15-17 Random movement of gas proceeds from a higher concentration to a lower concentration until a homogeneous mixture of gases is achieved.

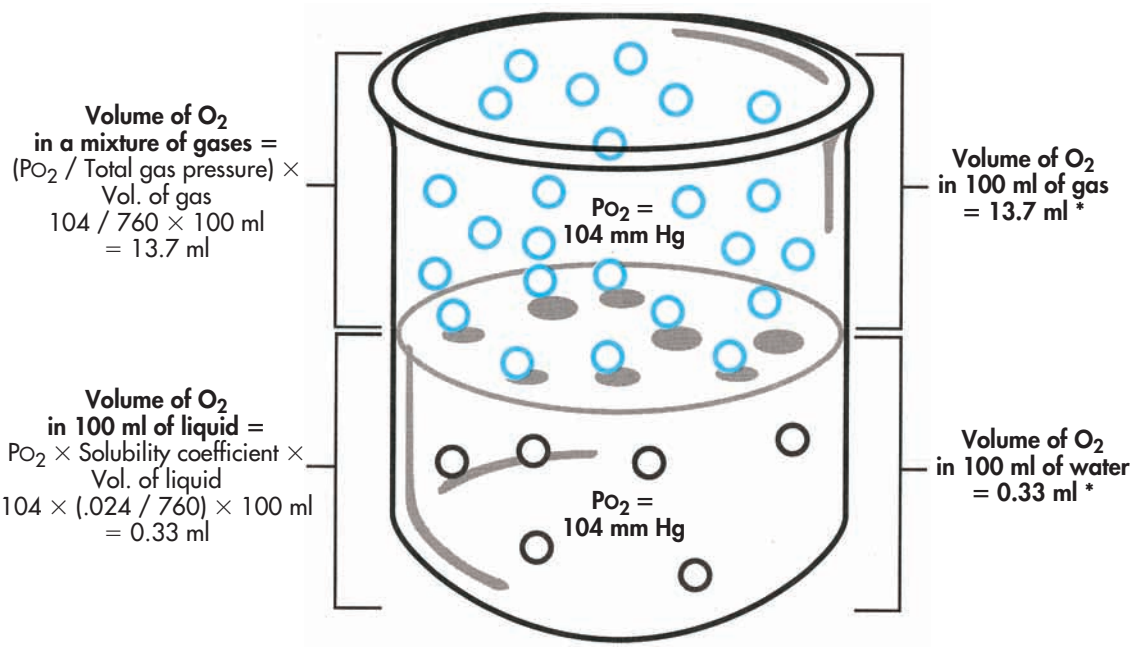

FIGURE 15-18 At equilibrium, the concentration of a gas in a liquid is determined by the partial pressure of the gas and by the solubility of the gas in the liquid at atmospheric pressure (760 mm Hg) and 98.6° F (37° C).

the blood. Carbon dioxide moves from the blood, where it is more concentrated, into the alveoli, where it is less concentrated (Figure 15-19).

NOTE
Oxygen and carbon dioxide do not readily dissolve in blood plasma. Transport molecules are required. These include hemoglobin for oxygen, and bicarbonate and hemoglobin for carbon dioxide.

The blood flowing through the pulmonary capillaries is separated from the alveolar air by a thin layer of tissue. This layer is known as the *respiratory membrane.* The membrane is composed of the alveolar wall (surfactant, epithelial cells, and basement membrane), interstitial fluid, and the wall of the pulmonary capillary (basement membrane and endothelial cells). The differences in the partial pressures of oxygen and carbon dioxide on the two sides of the membrane result in diffusion. Oxygen moves into the blood and carbon dioxide into the alveoli. With this diffusion, the capillary blood P_{O_2} level rises. The capillary blood P_{CO_2} level falls. Diffusion of these gases stops when alveolar and capillary partial pressures equalize. In healthy people this gas exchange occurs so quickly that the blood leaving the lungs to be pumped through the arteries has nearly the same P_{O_2} (80 to 100 mm Hg) and P_{CO_2} (35 to 40 mm Hg) as alveolar air.

The diffusion of gases at the capillary-alveolar level can be affected in a number of ways. Some respiratory diseases (e.g., emphysema) destroy and collapse the alveolar walls. This results in the formation of fewer but larger alveoli. The degenerative process reduces the total area available for diffusion. In some diseases the alveolar-capillary membrane becomes thick or less permeable. This forces gas molecules to travel farther. Thus it reduces the rate of diffusion. An example of such a disease is pulmonary edema. With this condition, fluid collects in the alveoli and pulmonary interstitial space. This forces gases to diffuse through a thicker than normal layer of fluid and tissue.

Oxygen Content of Blood

Oxygen is present in the blood in two forms: (1) physically dissolved in the blood and (2) chemically bound to hemoglobin (Hb) molecules. Compared with carbon dioxide and nitrogen, oxygen is relatively insoluble in water. Only 0.3 mL of oxygen can be dissolved in 100 mL of blood at the normal alveolar and arterial P_{O_2} of 100 mm Hg. In contrast, 197 mL of oxygen (about 98%) is carried in red blood cells. In red blood cells, it is chemically bound to hemoglobin **(oxyhemoglobin)** (Figure 15-20).

NOTE
Hematocrit is a blood test that measures the proportion of blood volume occupied by red blood cells. Normal values are about 46% for men and about 38% for women.

Hemoglobin can unload carbon dioxide and absorb oxygen 60 times faster than blood plasma.[4] When fully converted to oxyhemoglobin (HbO_2), each hemoglobin

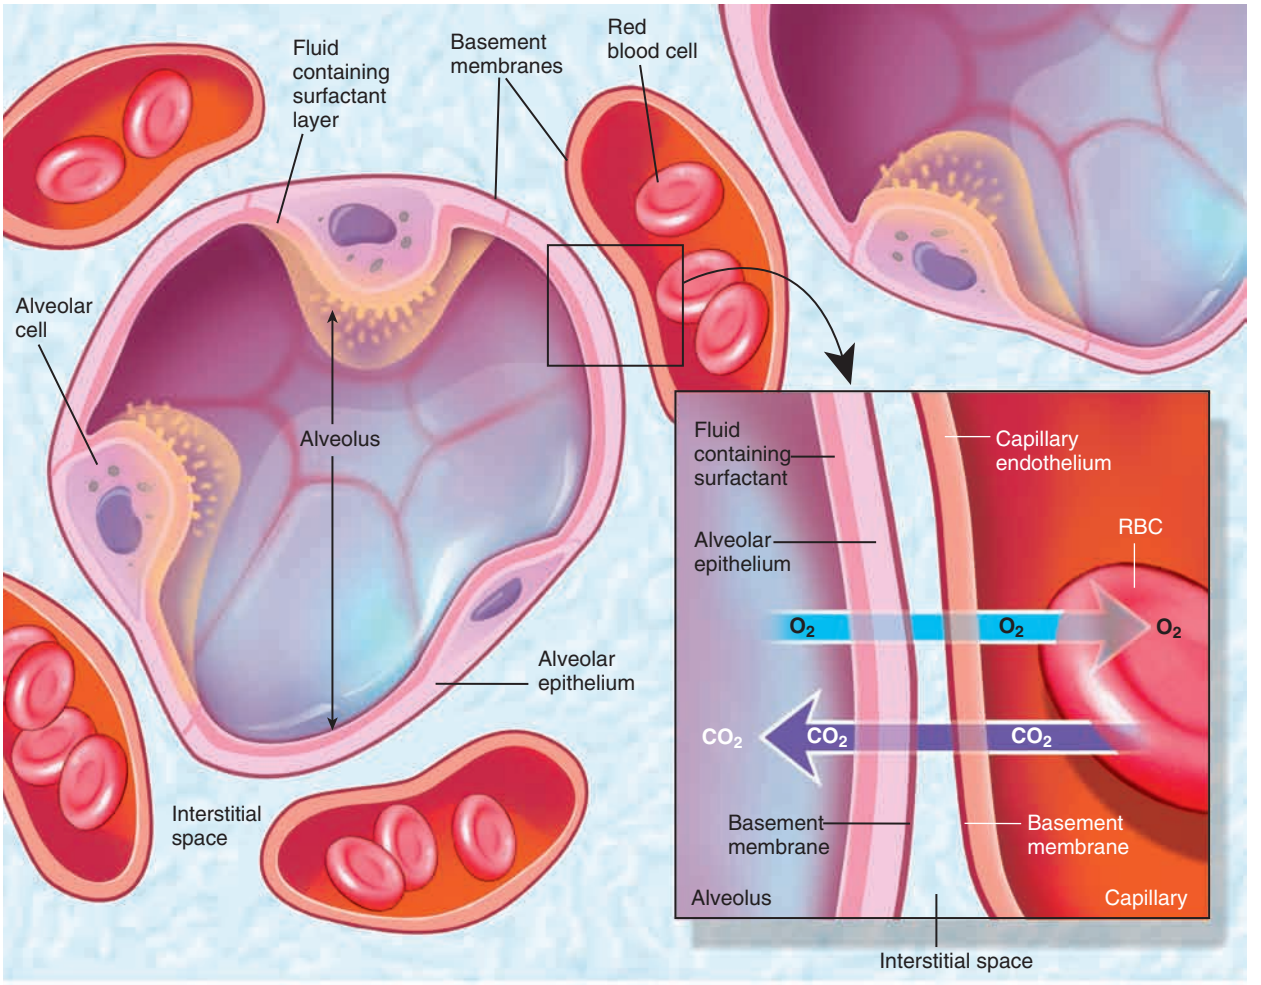

FIGURE 15-19 Gas exchange structure of the lung. Each alveolus is continually ventilated with fresh air. The inset shows a magnified view of the respiratory membrane composed of the alveolar wall (fluid coating, epithelial cells, and basement membrane), interstitial fluid, and the wall of a pulmonary capillary (basement membrane and endothelial cells). The gases, carbon dioxide (CO_2) and oxygen (O_2), diffuse across the respiratory membrane. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

molecule can carry four molecules of oxygen. At this point, the Hb molecule is said to be *fully saturated*. Hemoglobin nears full saturation at a P_{O_2} of 80 to 100 mm Hg.

The degree to which hemoglobin combines with oxygen increases rapidly when the P_{O_2} is 10 to 60 mm Hg. This is because about 90% of total hemoglobin is combined with oxygen when the P_{O_2} is 60 mm Hg. Further increases in P_{O_2} produce only small increases in the amount of oxygen bound to hemoglobin. If the P_{O_2} falls slightly, the amount of oxyhemoglobin decreases only slightly. It still provides adequate oxygenation to tissues. The body adapts to higher P_{O_2} values (Figure 15-21).

NOTE

The concept of the body adapting to higher partial pressure of oxygen (P_{O_2}) values is important when dealing with patient situations involving high altitudes, excessive exercise, or cardiac and pulmonary disease. The P_{O_2} in the blood plasma is the most important factor in determining the extent to which oxygen combines with hemoglobin. Oxyhemoglobin, however, does not contribute to the P_{O_2} of the blood. Only the physically dissolved oxygen molecules can create gas pressure. This oxygen uptake by hemoglobin molecules removes dissolved oxygen from blood plasma. It also maintains a low P_{O_2}, allowing diffusion to continue (see Figure 15-21). (Laws that affect gas pressures [e.g., Boyle's law, Dalton's law, and Henry's law] are further described in Chapter 45.)

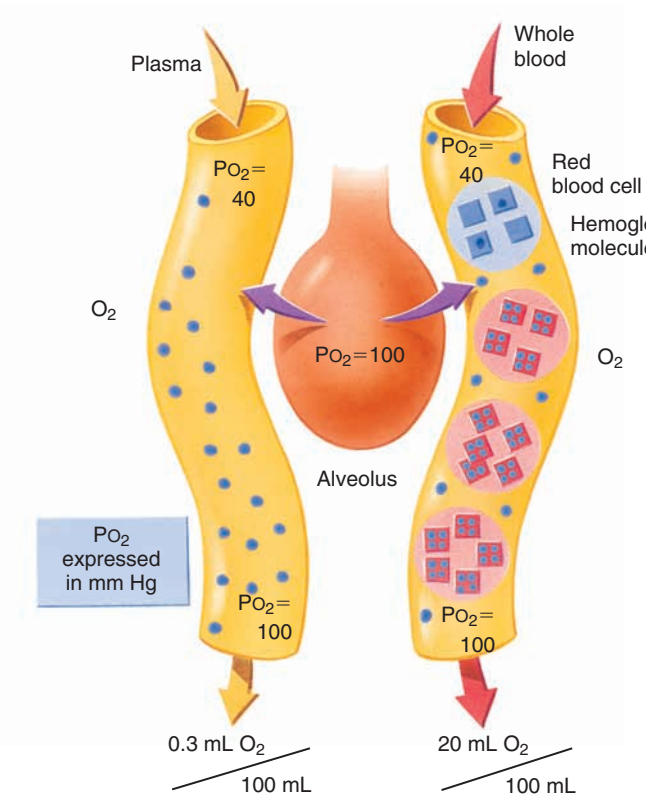

FIGURE 15-20 Oxygen-carrying capacity of the blood. If blood consisted only of plasma, the maximum amount of oxygen that could be transported would be only about 0.3 mL per 100 mL of blood. However, because the red blood cells contain hemoglobin molecules, which act as "oxygen sponges," the blood can actually carry up to 20 mL of dissolved O_2 per 100 mL of blood. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

NOTE
It should be noted that if the SaO_2 is 100% the PaO_2 can range from 80-500 mmHg. This explains the recommendation that SaO_2 be maintained at 94% in patients who have chest pain, stroke, or a return of spontaneous circulation. *More oxygen is not always better.*

Venous blood entering the lungs has a P_{O_2} of 40 mm Hg and a hemoglobin saturation of 75%. Oxygen diffuses from the alveoli (because of its higher P_{O_2} of 100 mm Hg) into the plasma. This diffusion raises the plasma P_{O_2}. This produces an increase in the uptake of oxygen by the hemoglobin molecules. In the tissue capillaries, this process is reversed. As the blood enters the capillaries, the plasma P_{O_2} is greater than the P_{O_2} in the fluid surrounding the capillaries. This causes diffusion across the capillary membranes to the cells of the tissues.

NOTE
Diagnostic tests that can be used in the field to monitor the oxygen content of blood and the effectiveness of ventilation include pulse oximetry monitoring, peak expiratory flow testing, end-tidal carbon dioxide monitoring, and esophageal detection device monitoring. (These techniques are described later in this chapter and in Chapter 24.)

Carbon Dioxide Content of Blood

As described in Chapter 11, the amount of carbon dioxide produced by the body is fairly constant. It is determined by the body's rate and type of metabolism. If the metabolic rate increases, more carbon dioxide is produced. For instance, this may occur during exercise. In contrast, as the metabolic rate decreases, less carbon dioxide is produced. This may occur during sleep. Certain types of metabolic processes also result in increased carbon dioxide production. An example is anaerobic metabolism that occurs in the absence of oxygen. Another example is the body's production of ketoacids when metabolism occurs in the absence of insulin.

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 227-230.

Carbon dioxide is transported in the blood in three major forms: plasma, blood proteins, and bicarbonate ions. As with oxygen, the solubility of carbon dioxide in water is minimal. It accounts for 8% of the carbon dioxide carried in plasma. About 20% of the carbon dioxide is present in blood proteins (including hemoglobin). About 72% is in the form of bicarbonate ions. When arterial blood flows through tissue capillaries, oxyhemoglobin gives up oxygen to the tissues. At the same time, carbon dioxide diffuses from the tissues into the blood. As a result, a small amount of the carbon dioxide dissolves in the plasma.

NOTE
The way in which a patient's lungs are ventilated can change the pH of blood. It also may enhance or hinder oxygenation at the tissue level. For example, carbon dioxide levels may be high (resulting in a drop in pH in capillary blood). As a result, the oxygen affinity for hemoglobin is reduced. On the other hand, if carbon dioxide levels are low (resulting in a rise in pH in capillary blood), the oxygen affinity for hemoglobin is increased. The response of hemoglobin to changes in pH is called the **Bohr effect** (Figure 15-22; also see Figure 15-23).

As described in Chapter 11, oxygen-free hemoglobin binds more readily to carbon dioxide than hemoglobin binds with oxygen. Thus some of the carbon dioxide that

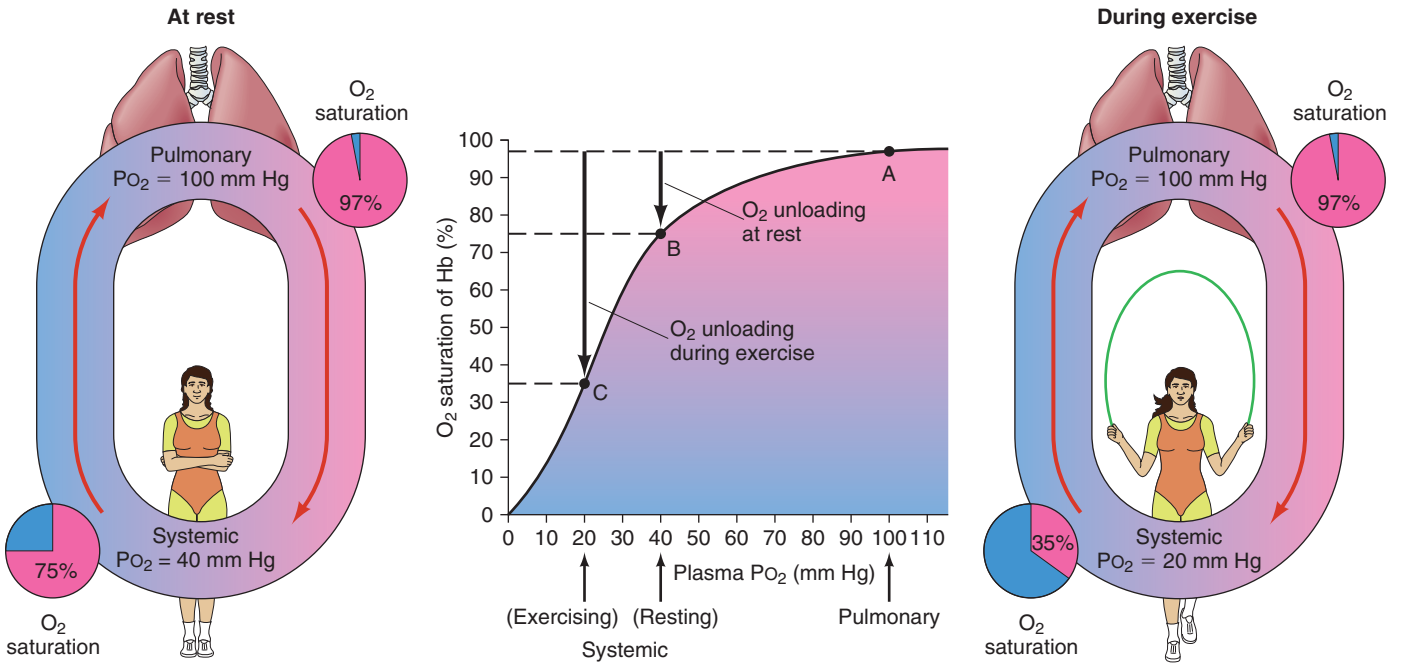

FIGURE 15-21 Oxygen (O_2) unloading at rest and during exercise. At rest, fully saturated hemoglobin (Hb) unloads almost 25% of its O_2 when it reaches the low partial pressure of oxygen (P_{O_2}) environment (40 mm Hg) in systemic tissues *(left inset)*. During exercise, the tissue P_{O_2} is even lower (20 mm Hg). Consequently, fully saturated Hb unloads about 70% of its O_2 *(right inset)*. As the graph shows, a slight drop in the tissue P_{O_2} (from *B* to *C*) greatly increases O_2 unloading. (Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 7, St Louis, 2007, Mosby.)

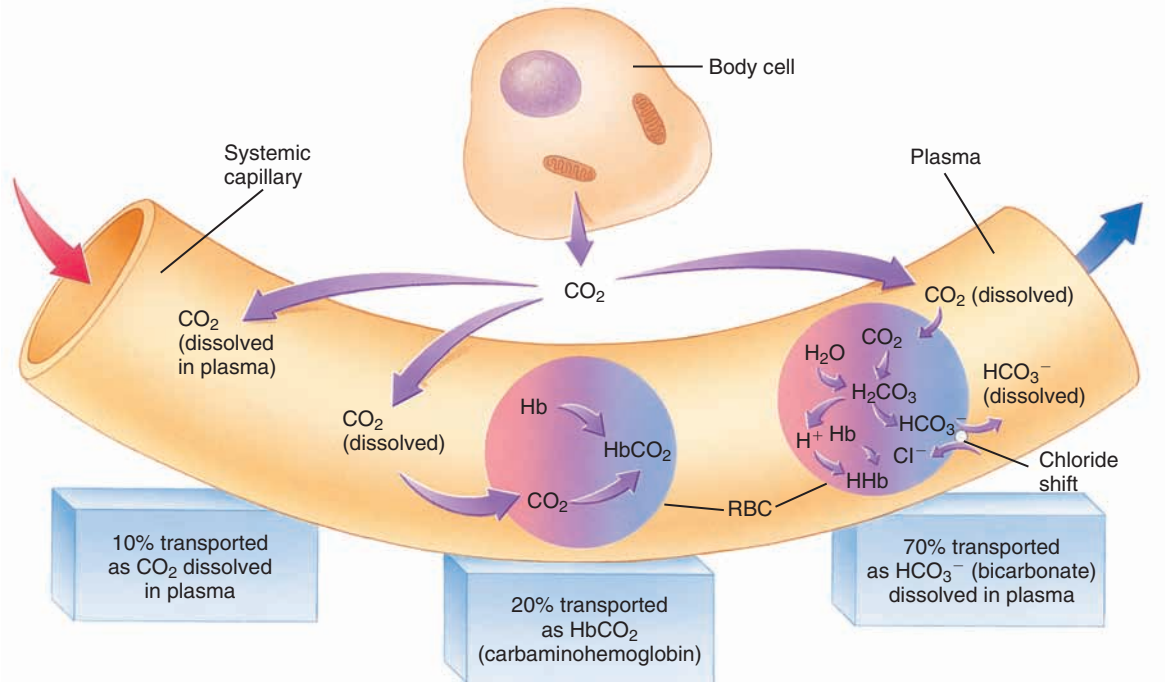

FIGURE 15-22 Interaction of the partial pressure of oxygen (P_{O_2}) and the partial pressure of carbon dioxide (P_{CO_2}) on gas transport by the blood. An increase in the P_{CO_2} in systemic tissues decreases the affinity between hemoglobin (Hb) and oxygen (O_2). This appears as a right shift of the oxygen-hemoglobin dissociation curve. The phenomenon is known as the *Bohr effect*. A right shift can also be caused by a decrease in the plasma pH. (Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 7, St Louis, 2007, Mosby.)

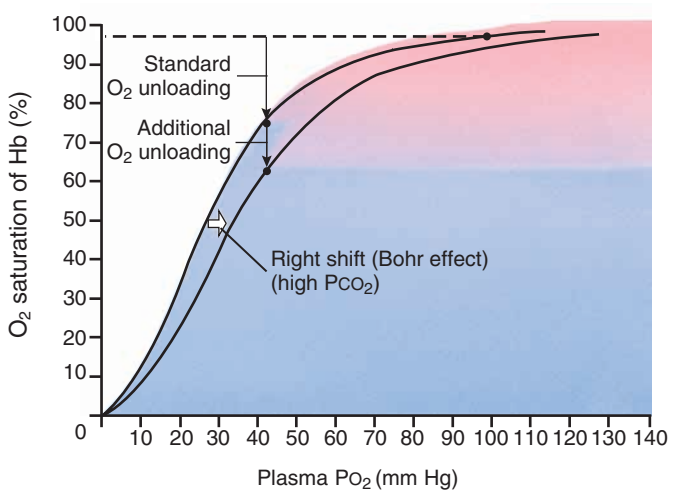

FIGURE 15-23 Carbon dioxide transport in the blood. Carbon dioxide (CO_2) dissolves in the plasma. Some of the dissolved CO_2 enters red blood cells (RBCs) and combines with hemoglobin (Hb) to form carbaminohemoglobin ($HbCO_2$). Some of the CO_2 enters RBCs and combines with water (H_2O) to form carbonic acid (H_2CO_3); this process is facilitated by an enzyme (carbonic anhydrase) present inside each cell. Carbonic acid then dissociates to form hydrogen ion (H+) and bicarbonate (HCO_3^-). The H+ combines with the hemoglobin. The HCO_3^- diffuses down its concentration gradient into the plasma. As HCO_3^- leaves each red blood cell, chloride (Cl^-) enters. This phenomenon is known as the *chloride shift*. It prevents an imbalance in charge. (Patton KT, Thibodeau GA: *Anatomy and physiology*, ed 7, St Louis, 2007, Mosby.)

diffuses into red blood cells binds to hemoglobin to form carbaminohemoglobin (HbNHCOOH). The remainder of the carbon dioxide reacts with water to form carbonic acid. Bicarbonate, in contrast to carbon dioxide, is very soluble in water. Venous blood rich in carbon dioxide is returned to the lungs. Because the blood P_{CO_2} is greater than that in the alveoli, carbon dioxide from the blood diffuses into the alveoli. From there it is exhaled and eliminated from the body (Figure 15-23).

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 225-227.

Factors That Influence Blood Oxygenation

In healthy people, the process of breathing fully oxygenates the blood at the alveolar-capillary level. It also allows carbon dioxide to be eliminated. The movement and utilization of oxygen in the body to perfuse tissues can be described by the Fick principle. (This is a method also used to measure cardiac output.) According to the **Fick principle,** the amount of oxygen the lungs deliver to the blood is directly related to the amount of oxygen the body consumes. The movement and utilization of oxygen are based on the following conditions[9]:

1. An adequate amount of oxygen must be available to saturate the hemoglobin on red blood cells as they pass by alveolar membranes in the lungs. This requires adequate ventilation of the lungs through the patient's airway, a high partial pressure of oxygen in inspired air (F_{IO_2}), and minimal obstruction to the diffusion of oxygen across the alveolar-capillary membrane.
2. The red blood cells must be circulated to the tissue cells. This requires adequate cardiac function, an adequate volume of blood flow, and proper routing of blood through the vascular channels.
3. The red blood cells must be able to load oxygen in the pulmonary capillaries. They also must be able to unload the oxygen at the site of peripheral tissue cells. This requires normal hemoglobin levels, circulation of the oxygenated red blood cells to the tissues in need, close approximation of the cells to the capillaries to allow for diffusion of oxygen, and ideal conditions of pH, temperature, and other factors.

NOTE
In medical care, F_{IO_2} is the fraction of inspired oxygen in a gas mixture. It is expressed as a number from 0 (0%) to 1 (100%). For example, the F_{IO_2} of normal room air is 0.21 (21%). The F_{IO_2} can be manipulated with airway devices that provide supplemental oxygen.

Hypoxemia is a state of decreased oxygen content of the arterial blood. It may lead to **hypoxia** (decreased oxygen content at the tissue level). Some abnormal conditions can result in inadequate blood oxygenation (Box 15-2). These conditions are described later in this chapter and throughout this text by subject matter.

DID YOU KNOW?
Ventilation/Perfusion Ratio
In respiratory physiology, the ventilation/perfusion ratio (V/Q ratio) is a measurement used to assess the efficiency and adequacy of the matching of two variables: alveolar ventilation and pulmonary perfusion.[10]

V (ventilation)—the air that reaches the lungs

Q (perfusion)—the blood that reaches the lungs

These two variables constitute the main determinants of the blood oxygen concentration. The matching of these two variables is vital to life. The V/Q ratio can be affected by circulation disturbances in blood volume that may result from cardiorespiratory disease, trauma, and systemic illness.

The V/Q ratio is measured by using a ventilation/perfusion scan. This imaging test gauges the circulation of air and blood in a patient's lungs. The ventilation part of the test evaluates the ability of air to reach all parts of the lungs. The perfusion part

*Ventilated alveoli that are not perfused or perfused alveoli that are not ventilated.

of the test evaluates how well the blood circulates within the lungs. Normally, alveolar ventilation is about 4 L/minute, and pulmonary capillary blood flow (perfusion) is about 5 L/minute. Therefore, the normal V/Q ratio is 4:5, or 0.8. An area with no ventilation (V/Q = 0) is called a *shunt.* An area with no perfusion (V/Q of infinity) is called *dead space.* An increased V/Q ratio is seen with disorders in which ventilation is greater than perfusion (increased partial pressure of arterial oxygen [PaO_2], decreased partial pressure of arterial carbon dioxide [$PaCO_2$]). Examples of such disorders include pulmonary embolism and pneumothorax. A decreased V/Q ratio is seen with disorders in which perfusion is greater than ventilation and there is an increased shunting of blood. Examples of these disorders include obstructive lung diseases that cause alveolar hypoventilation.

Although the V/Q ratio is not a prehospital evaluation tool, it is important that paramedics understand the relationship between alveolar ventilation and pulmonary perfusion. It also is important that they understand the way ventilation/perfusion mismatching (ventilated alveoli that are not perfused or perfused alveoli that are not ventilated) can affect patients with respiratory compromise.

Blood Volume Circulation Disturbances

Disturbances in the effective circulation of blood can affect the body's ability to nourish the tissues and maintain adequate cellular oxygenation. These circulation disturbances can result from cardiac disease, trauma, and problems with systemic vascular resistance[11]: The heart rate must be capable of circulating blood through the vascular system for adequate tissue perfusion (Box 15-3). Conditions that can negatively affect this include conduction disturbances, tachycardia, bradycardia, and inadequate preload that diminishes stroke volume. The role of the autonomic nervous system and medications that affect alpha and beta stimulation of the heart also are important for adequate cardiac function.

Finally, vascular resistance in the systemic circulation *(total peripheral resistance)* must be adequate to maintain blood pressure and cardiac output. One factor that affects total peripheral resistance is the capacitance of blood vessels (functioning precapillary arterioles). Another is the smooth muscle effects initiated by alpha and beta cholinergic receptors. As described in Chapter 11, total peripheral resistance can be affected by hypoxia, acidosis and the effectiveness of the buffer systems, temperature changes, neural factors, and catecholamines.

BOX 15-3 Blood Volume Circulation Disturbances

Blood volume circulation disturbances can occur as a result of conditions that affect vascular resistance, cardiac disease that affects cardiac output, injury, and systemic illness.[11]

Changes in Vascular Resistance
Orthostatic hypotension
Oncotic fluid pressure
Hydrostatic fluid pressure
Capacitance of the venules and veins

Cardiac Disease Affecting Cardiac Output
Heart rate (tachycardia, bradycardia)
Stroke volume (preload, afterload)
Alpha and beta stimulation of the heart
Conduction disturbances
Congestive heart failure

Injury
Head, chest, and spinal trauma
Blood loss
Shock

Systemic Illness
Acid-base disturbances
Anemia
Infection
Renal disease
Respiratory disease

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 238-240.

REGULATION OF RESPIRATION

Respiration is controlled by a number of factors. When paramedics evaluate a patient, key elements they must consider include the various mechanisms responsible for rhythmic ventilation. The rate and depth of breathing are also crucial factors.

Voluntary Control of Respiration

Breathing is mainly an involuntary process. Within limits, however, the pattern of respiration can be consciously altered. For example, voluntary hyperventilation can lead to a decrease in the blood P_{CO_2}, vasodilation of the peripheral blood vessels, a decrease in blood pressure, or a combination of these effects. Hyperventilation causes excessive loss of exhaled carbon dioxide, which produces **hypocarbia,** resulting in cerebral vascular constriction, reduced cerebral perfusion, paresthesia (tingling sensation), dizziness, or even feelings of euphoria.

Breathing also can be affected by voluntary apnea. An example of this is when children hold their breath. In such cases the arterial blood P_{CO_2} increases, whereas the P_{O_2} decreases. As the apneic period continues, the abnormal levels of P_{CO_2} and P_{O_2} trigger the respiratory centers. These changes in the levels override the child's conscious control of breathing. If loss of consciousness occurs, the respiratory center resumes normal function.

CRITICAL THINKING
If a prolonged, deep breath is held, what vagal effects might the patient experience?

Nervous Control of Respiration

The inspiratory muscles are the diaphragm and intercostal muscles. These are composed of skeletal muscle. They cannot contract unless they are stimulated by nerve impulses. The two phrenic nerves responsible for moving the diaphragm originate from the third, fourth, and fifth cervical spinal nerves. The 11 pairs of intercostal nerves originate from the first through the eleventh thoracic spinal nerves. The nerve impulses that control these respiratory muscles originate in neurons of the medulla. This inspiratory and expiratory center is influenced by the pons, hypothalamus, the reticular activating system (RAS), and the cerebral cortex. The center is innervated by afferent activity in the vagus, glossopharyngeal, and somatic nerves (Figure 15-24).

NOTE
The respiratory center in the medulla is bilateral. Each lateral area is made up of two groups of neurons: the *dorsal respiratory group (DRG)* and the *ventral respiratory group (VRG).* The DRG is involved in the generation of respiratory rhythm. This group is primarily responsible for inspiration. The VRG has both inspiratory and expiratory neurons. This group plays a secondary role in inspiratory activity, after the DRG. The neurons in the VRG remain almost inactive during normal quiet respiration. When the respiratory drive for increased pulmonary ventilation becomes greater than normal, respiratory signals spill over into the VRG from the DRG area. The VRG then contributes to the respiratory drive. The VRG is responsible for motor control of inspiratory and expiratory muscles during exercise. Together, these two groups of neurons are responsible for the basic rhythm of ventilation.

The inspiratory center neurons are spontaneously active. They exhibit a pattern of activity followed by fatigue and then activity again. When active, they send impulses along the spinal cord to the phrenic and intercostal nerves. This stimulates the muscles of inspiration. (Head and spinal trauma, stroke, and some diseases can interrupt nervous control.)

The expiratory center is inactive during quiet respiration. The exact nervous system mechanisms that control the activity of this center are unknown. However, the

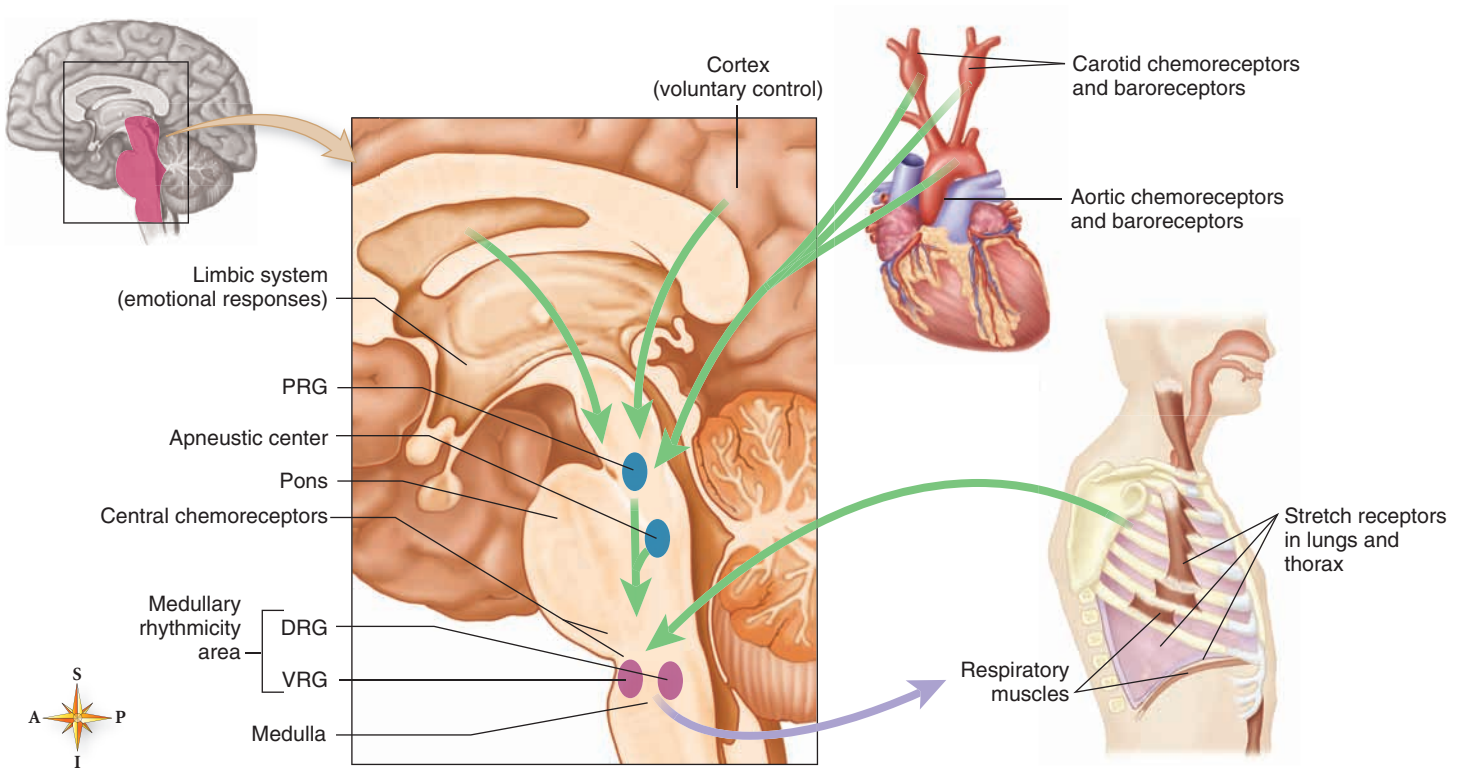

FIGURE 15-24 Regulation of breathing. The dorsal respiratory group (DRG) and ventral respiratory group (VRG) of the medulla represent the medullary rhythmicity area. The pontine respiratory group (PRG, or pneumotaxic center) and apneustic center of the pons influence the basic respiratory rhythm by means of neural input to the medullary rhythmicity area. The brainstem also receives input from other parts of the body; information from chemoreceptors, baroreceptors, and stretch receptors can alter the basic breathing pattern, as can emotional (limbic) and sensory input. Despite these subconscious reflexes, the cerebral cortex can override the "automatic" control of breathing to some extent to allow such activities as singing or blowing up a balloon. Green arrows show flow of information to the respiratory control centers. The purple arrow shows the flow of information from the control centers to the respiratory muscles that drive breathing. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

expiratory center appears to be stimulated when the activity of the inspiratory center increases. (For example, this may occur during heavy or labored breathing.) When activated, the expiratory center counters the inspiratory center, responding to a forceful inspiration with a forceful expiration.

Two distinct neural mechanisms are responsible for the basic respiratory rhythm established by the inspiratory and expiratory centers: the **Hering-Breuer reflex** and the pneumotaxic center. The vagus nerve conveys sensory information from the thoracic and abdominal organs. Some of the vagus nerve fibers end in stretch or inflation receptors in the walls of the bronchi, bronchioles, and lungs. When the stretch receptors are stimulated by expansion of the lungs, information is communicated by the vagus nerve to the medulla. The medulla produces discharges of inhibitory impulses. This, in turn, causes inspiration to stop *(inflation reflex)*. The cessation of inspiration is followed by expiration or deflation of the lungs. As expiration continues, the stretch receptors are no longer stimulated. This allows the inspiratory center to become active again *(deflation reflex)*. Thus the Hering-Breuer reflexes limit inspiration and prevent overinflation of the lungs.

The **pneumotaxic center** is located in the pons above the respiratory center in the medulla. It has an inhibitory effect on the inspiratory center. When the activity of the inspiratory center stops, inhibitory impulses from the pneumotaxic center stop. When this occurs, the inspiratory center is free to send impulses to initiate inspiration again. The pneumotaxic center appears to be active only in labored breathing. In quiet breathing the stretch receptors are the main control mechanisms for rhythmic breathing.

The **apneustic center** is located in the lower portion of the pons. Nerve impulses from this area stimulate the inspiratory center. The apneustic center neurons are constantly active during normal respiratory rates. However, they are overridden by the pneumotaxic center when the demand for increased ventilation arises.

CRITICAL THINKING
What change in breathing would you expect in a patient who has an injury affecting the pons?

Chemical Control of Respiration

The activities of the respiratory centers are determined by changes in oxygen and carbon dioxide concentrations. They also are determined by the hydrogen ion concentration (pH) of body fluids. (An example of such a fluid is cerebrospinal fluid.) The partial pressure of carbon dioxide is the major factor that controls respiration.[12]

The chemoreceptive area in the medulla has neurons that are sensitive to changes in carbon dioxide and pH. An increase or decrease in the plasma P_{CO_2} is accompanied by changes in pH. An increase in the P_{CO_2} and the resulting decrease in pH adversely affect cellular metabolism. Excess carbon dioxide must be eliminated to return the pH to normal. For example, the body responds to an increase in P_{CO_2} of 5 mm Hg with an increase in ventilation of 100%. On the other hand, a decrease in P_{CO_2} inhibits ventilation. The carbon dioxide created by normal metabolism is allowed to accumulate and return the P_{CO_2} to normal. Through these adaptive measures, the P_{CO_2} is kept within a normal range of 35 to 45 mm Hg (Figure 15-25).

Compared with the body's sensitivity to pH and carbon dioxide levels, oxygen plays a fairly small part in regulating respiration. However, if the P_{O_2} levels in the arterial blood fall and the pH and P_{CO_2} are held constant, ventilation increases.

Chemoreceptors monitor the arterial P_{O_2}. They are located in the medulla and peripherally at the bifurcation of the common carotid arteries and in the arch of the aorta. These peripheral receptors are known as the **carotid and aortic bodies.** The carotid and aortic bodies are in intimate contact with the arterial blood of the great vessels. Thus their blood supply is greater than their use of oxygen. Moreover, the P_{O_2} of their tissues is very close to that of arterial blood. The nerve fibers from these bodies enter the brainstem. There they synapse with the neurons of the medulla and initiate a respiratory response.

Carbon dioxide and hydrogen ion concentrations are the major regulators of respiration. However, a reduced P_{O_2} in the arterial blood can play a part in regulating respiration. When a patient is hypotensive (e.g., in shock), the P_{O_2} in the arterial blood may fall to low levels. This stimulates the sensory receptors in the carotid and aortic bodies. This, in turn, leads to an increased rate and depth of ventilation. This can occur without a significant change in the blood P_{CO_2}. However, it usually is accompanied by metabolic acidosis, which occurs secondary to anaerobic metabolism[12] (as described in Chapter 11).

LOOK AGAIN
See Chapter 11: General Principles of Pathophysiology, pp. 228-230.

P_{O_2} plays a role in respiratory regulation at high altitudes. At these altitudes, the barometric pressure is low. This causes the P_{O_2} in the arterial blood to drop. The low P_{O_2} levels stimulate the carotid and aortic bodies. Lowered barometric pressure does not affect the body's ability to eliminate carbon dioxide. The increase in ventilation (triggered by the lowered arterial P_{O_2}) results in a drop in the carbon dioxide levels in the blood.

Patients with severe emphysema or chronic bronchitis have chronically elevated P_{CO_2} levels. These patients may rely on the low P_{O_2} as the stimulus for ventilation **(hypoxic drive).** In diseases with chronic elevation of P_{CO_2}, the chemoreceptors become less sensitive to a high carbon dioxide level. They fail to be stimulated by it. Over time, hypoxia becomes the only remaining respiratory drive.

Control of Respiration by Other Factors

A number of other factors may play a role in the control of respiration. These include body temperature, drugs and medications, pain, emotion, and sleep.

An increase in body temperature can affect the respiratory center neurons. Such an increase may be caused by a febrile illness or an increase in physical activity. The increase can cause an increase in ventilation. On the other hand, major decreases in body temperature can lower the ventilation rate. An extreme example of this can occur during severe hypothermia. With this, patients can appear almost apneic (see Chapter 45).

Some drugs, such as ***epinephrine,*** stimulate ventilation. They do this by promoting cellular metabolism during stressful events and vigorous exercise. However, drugs such as ***diazepam*** and ***morphine*** may reduce ventilations. A person who takes an overdose of narcotics or barbiturates can become apneic.

Pain anywhere in the body may produce a reflex stimulation of ventilation. Examples include performing a sternal rub on a patient or stepping into a cold shower. Also, certain emotions, such as laughing or crying, require an increase in the movement of air into and out of the lungs. Situations involving fear and anger cause rapid breathing.

As the body's activity and metabolism slow, so does the formation of impulses to stimulate the respiratory centers. During times of decreased activity, ventilation also decreases.

Modified Forms of Respiration

The cough reflex and the sneeze reflex are protective mechanisms. The function of each is to dislodge foreign matter or irritants from the respiratory passages. Coughing generally is preceded by an inspiration of greater than normal force (about 2.5 L of gas). The glottis then closes, and the muscles of the thorax contract forcibly. This causes an increase in intrapulmonic pressure. The pressure change in the lungs increases to about 100 mm Hg.[13] When this pressure is reached, the vocal cords part, and air escapes from the lungs at high velocity. This air carries foreign materials and particles of mucus out of the lungs.

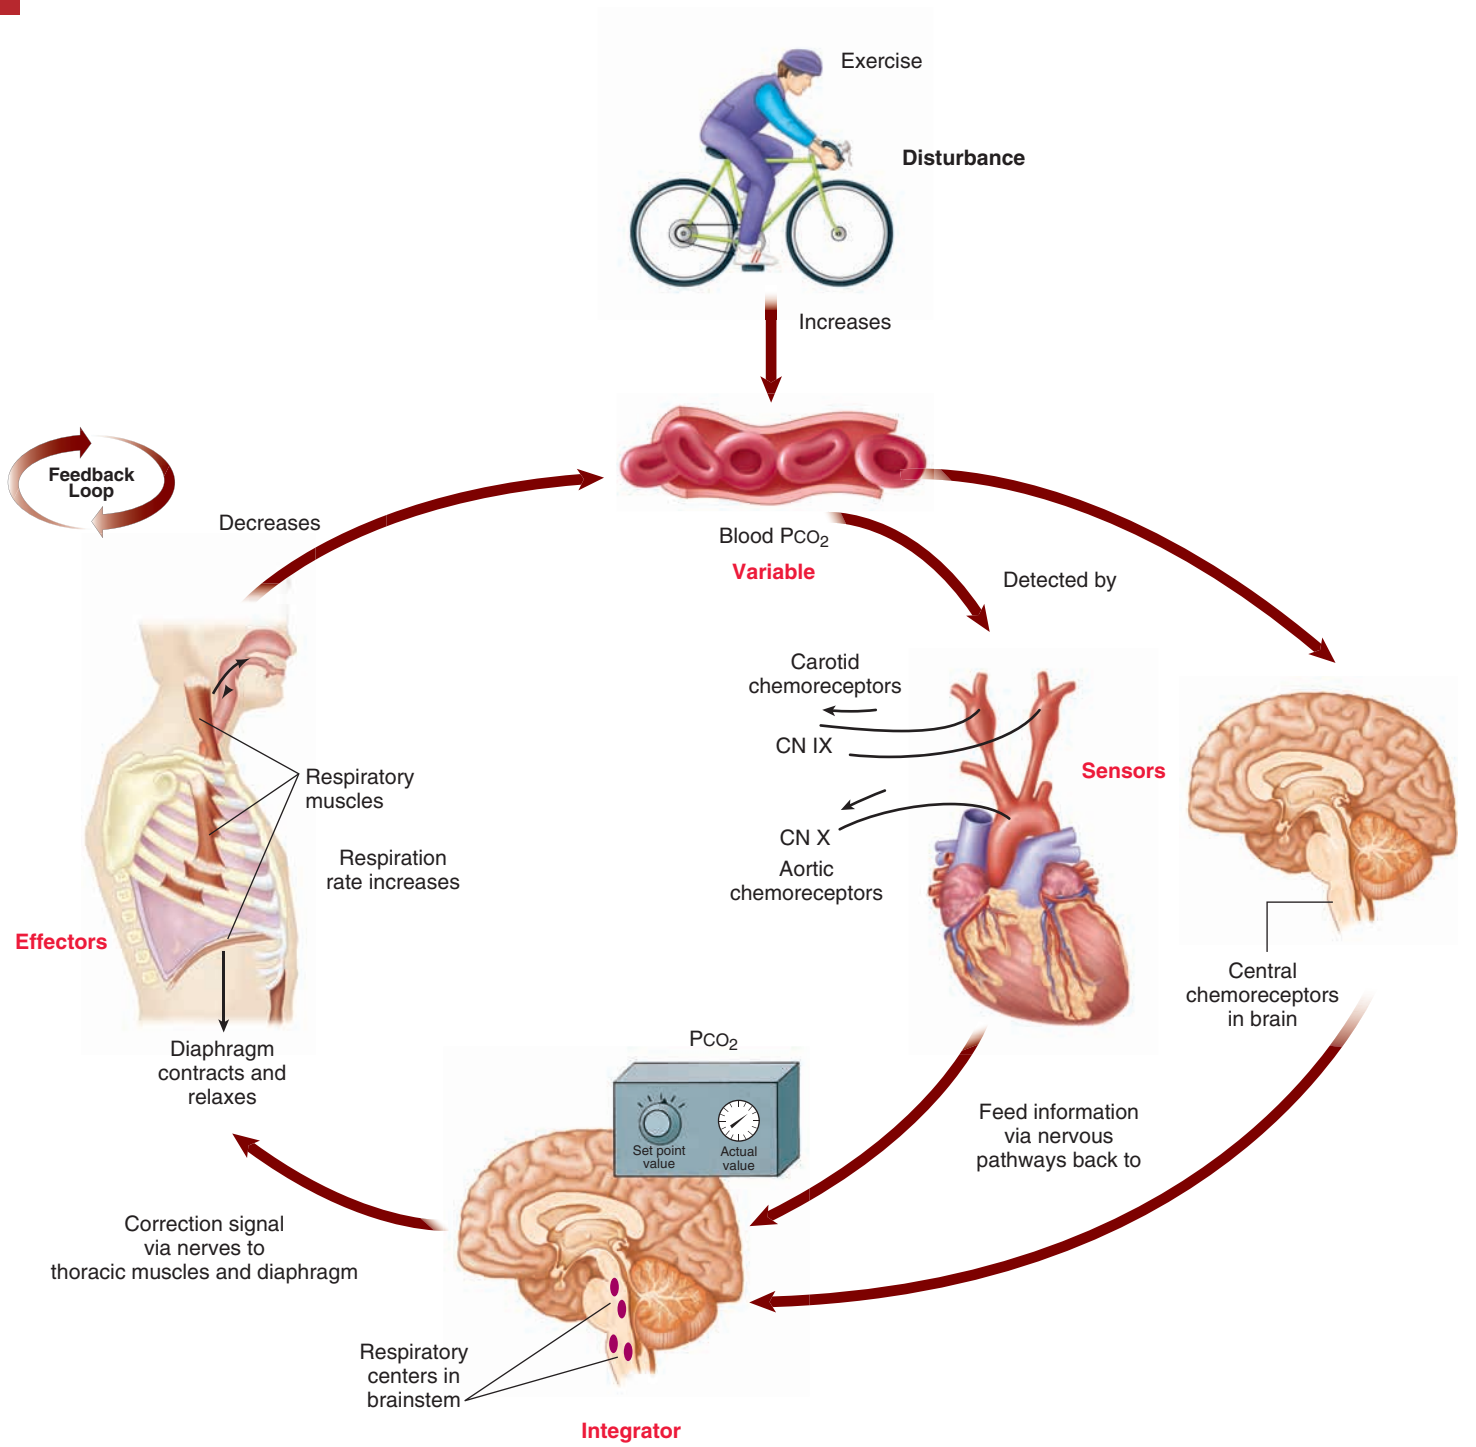

FIGURE 15-25 Negative feedback control of respiration. The diagram summarizes the feedback loop by which the respiratory rate is increased in response to a high plasma partial pressure of carbon dioxide (P_{CO_2}). Increased cellular respiration during exercise causes a rise in the plasma P_{CO_2}. This is detected by central chemoreceptors in the brain and perhaps by peripheral chemoreceptors in the carotid sinus and aorta. Feedback information is relayed to integrators in the brainstem. These respond to the increase in P_{CO_2} above the set point by sending nervous correction signals to the respiratory muscles, which act as effectors. The effector muscles increase their alternating contraction and relaxation, thereby increasing the rate of respiration. As the respiration rate increases, the rate of CO_2 loss from the body increases and the P_{CO_2} drops accordingly. This brings the plasma P_{CO_2} back to its set point value. (Patton KT, Thibodeau GA: *Anatomy and physiology,* ed 7, St Louis, 2007, Mosby.)

Sneezing is a violent expulsion of gas. The gas is forced or directed through the nasal cavity. It may occur as a result of nasal irritants, stimulation of the fifth cranial nerve (trigeminal nerve) in the nose, or exposure to bright lights. During the sneeze reflex, the uvula and the soft palate are depressed to direct air through both the nasal passages and the oral cavity.

Other forms of modified respiration include the sigh and the hiccough (in rare cases, these are chronic disorders). Sighing is a slow, deep inspiration followed by a prolonged expiration. This modified respiratory effort is thought to be a protective reflex to hyperinflate the lungs and to reexpand alveoli that might have been collapsed (atelectasis).

The hiccough results from a spasmodic contraction of the diaphragm with the sudden inspiration cut short by the closure of the glottis. Hiccoughs serve no known useful physiological purpose. They usually stop with time. However, they may indicate a pathological condition.

Special Considerations in Older Patients

Respiratory disorders create distinctive problems for the older patient. As a result of aging, the respiratory function of older patients may be compromised. Pulmonary changes that occur as a result of aging reduce vital capacity (Figure 15-26). They also increase the physiological dead space.

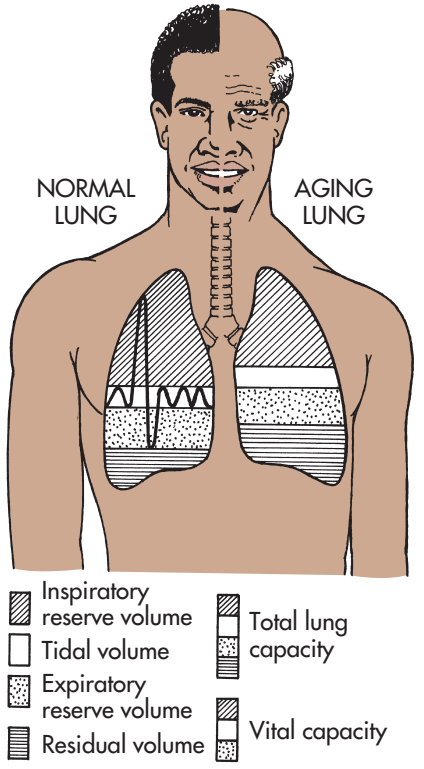

FIGURE 15-26 Changes in lung volumes with aging. Note particularly the decrease in vital capacity and the increase in residual volume that occur with aging. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2009, Mosby.)

Ventilation/perfusion mismatching also tends to increase. This leads to a gradually lowered P_{O_2}. The changes in pulmonary physiology include the following[14]:

1. Alterations in lung and chest wall compliance
   - Increased thoracic rigidity
   - Decreased elastic recoil (total lung capacity remains unchanged because of opposing loss of chest wall compliance and weakened respiratory muscles)
2. Enlarged alveolar ducts and sacs
   - Fewer alveoli
   - Less alveolar surface for gas exchange

The aging process also changes the body's ventilatory control mechanisms. As a person grows older, for example, the body's arterial P_{O_2} falls. Yet no significant change in arterial P_{CO_2} occurs. Several methods have been developed to calculate the expected P_{O_2} in older people. One method is to keep in mind that a person who is 70 years old is expected to have a P_{O_2} of 70 mm Hg. Using this value as a baseline, the expected change is a 1 mm Hg decrease in P_{O_2} for every year over 70 or a 1 mm Hg increase in P_{O_2} for every year under 70. For example, a person who is 75 years old would be expected to have a P_{O_2} of 65 mm Hg. A person who is 65 years old would be expected to have a P_{O_2} of 75 mm Hg.[15]

The functioning of the body's chemoreceptors also declines with age. This results in a diminished ventilatory response to hypoxia, hypercapnia, and similar conditions. It also may predispose the older individual to respiratory failure. It is important that older patients with respiratory compromise from any cause receive immediate intervention, oxygenation, and ventilatory support.

SECTION THREE
Respiratory Pathophysiology

Many conditions can cause respiratory compromise and hypoxia (Table 15-2). Some of these conditions are described in this chapter and throughout the text by subject matter.[11]

UPPER AIRWAY OBSTRUCTION

A common cause of poor ventilation is upper airway obstruction. In patients who are conscious, this type of obstruction typically is caused by inhalation of food, a foreign body, or fluid (vomitus, saliva, blood, neutral liquids). In any patient who has poor ventilation from any cause, the most critical lifesaving maneuvers a paramedic can perform are establishing and maintaining a clear airway. This should always be a first-order priority of patient care. Early detection, early intervention, and education of the general public in basic life support measures are major factors in preventing unnecessary deaths from airway compromise.

TABLE 15-2 Conditions That Can Cause Respiratory Compromise

Interruption of Nervous Control
Drugs
Trauma
Muscular dystrophy
Poliomyelitis
Neuromuscular junction blocking agent

Structural Damage to the Thorax
Chest trauma

Bronchoconstriction
Respiratory diseases

Disruption of Airway Patency
Infection
Trauma/burns
Foreign body obstruction
Allergic reaction
Unconsciousness (loss of airway tone)

Oxygen Deprivation
Suffocation
Strangulation
Oxygen-deficient atmosphere

External Respiration (Environmental Factors)
Altitude
Closed environment
Toxic or poisonous environment

Internal Respiration (Pathology Related to Changes in Alveolar-Capillary Gas Exchange)
Emphysema
Pulmonary edema
Pneumonia
Environmental/occupational exposure
Drowning

Ventilation Deficiencies
Tachypnea
Mechanical ventilation with noncompliant lungs
Breathing against an elevated diaphragm

Decreases in Lung Compliance
Pneumonia
Cystic fibrosis
Trauma

Ventilation/Perfusion Mismatch
Ventilation Defects
Pulmonary edema
Pneumonia
Atelectasis
Obstruction caused by mucous plugs
Increased dead space ventilation as a result of emphysema

Perfusion Defects
Pulmonary emboli
Disruption of normal chest architecture

Disruption in Oxygen Transport with Diminished Oxygen-Carrying Capacity
Anemia
Blood loss

Disruption in Effective Circulation
Shock
Blood loss
Diminished peripheral resistance
Cardiac failure
Emboli
Increased capillary permeability

Disruptions at the Cellular Level
Acid-base disturbances
Poisons/toxins
Blood sugar changes
Hormone effects
Drugs
Hypoxia

NOTE
Brain damage may occur 4 to 6 minutes after interruption of breathing and circulation. After 6 minutes of circulatory arrest, brain damage almost always occurs. After 10 minutes of circulatory arrest, some portions of the brain have been irreversibly damaged to the point of death.[2]

Foreign Body Airway Obstruction

About 3000 deaths each year result from foreign body obstruction of the airway.[16] Immediate removal of the obstruction might have prevented the resulting hypoxemia, unconsciousness, or cardiopulmonary arrest that caused these deaths. The management of foreign body airway obstruction by health care professionals, as recommended by the American Heart Association, is summarized in Table 15-3.

NOTE
Methods for relieving foreign body airway obstruction (FBAO) in an unconscious victim of any age have been simplified for lay rescuers. Lay rescuers should begin standard cardiopulmonary resuscitation (CPR) when an unrelieved, responsive choking victim becomes unresponsive or when an unresponsive person suspected of having an FBAO is encountered, evaluated, and treated. The only difference from regular CPR is that the lay rescuer should open the airway widely whenever ventilations are attempted. This is done to look for a foreign object and remove it if seen. Blind finger sweeps are not to be used by lay rescuers for victims of any age.

TABLE 15-3 Management of Foreign Body Airway Obstruction

Infant (<1 yr)	Objectives	Adult (>12 to 14 yr)	Child (1-12 to 14 yr)
Conscious victim	1. Assessment: Check for signs of severe airway obstruction.	Ask, "Are you choking?" Determine whether victim can cough or speak.	Observe for breathing difficulty.
	2. Act to relieve obstruction.	Perform subdiaphragmatic abdominal thrusts until object is expelled or patient loses consciousness.	Give five back blows. Give five chest thrusts until the object is expelled or the baby becomes unresponsive.
	3. Be persistent.		
	4. Position victim.		
Victim who loses consciousness		Turn on back as unit, supporting head and neck; position face up, arms by sides.	
	5. Check for foreign body.		
	6. Give rescue breaths.	Open airway with head-tilt chin-lift maneuver. Check for foreign body. Attempt rescue breathing (slow ventilations [1 sec]). If first ventilation attempt is unsuccessful, reposition head and reattempt ventilation.	
	7. Act to relieve obstruction.	Begin cardiopulmonary resuscitation (CPR). Check for foreign body each time airway is opened.	
		Repeat steps 6 through 7 until obstruction is relieved or until advanced procedures become possible (i.e., use of Kelly clamp or Magill forceps, or cricothyrotomy).	
Unconscious victim	1. Assessment: Determine unresponsiveness.	Tap or gently shake shoulder. Shout, "Are you okay?"	Tap or gently shake shoulder.
		Send someone to activate EMS.	
	2. Position victim.	Turn on back as unit, supporting head and neck; position face up, arms by sides.	
	3. Open airway.	Open airway with head-tilt chin-lift maneuver.	Open airway with head-tilt chin-lift maneuver without hyperextension.
	4. Assessment: Determine breathlessness.	Maintain an open airway. Place ear over mouth; observe chest. Look, listen, and feel for breathing (no longer than 10 seconds).	
	5. Give rescue breaths.	Seal mouth to mouth with barrier device or bag-valve device.	Seal mouth to nose/mouth with barrier device.
		Attempt rescue breathing (give 2 ventilations 1 sec each). If first ventilation is unsuccessful, reposition head and reattempt ventilation.	
	6. Act to relieve obstruction.	Begin CPR.	
	7. Check for foreign body.	Check for foreign object each time you open the airway.	
	8. Provide rescue breathing.		
	9. Be persistent.	Check for foreign object each time you open the airway until advanced procedures become possible (i.e., use of Kelly clamp or Magill forceps, or cricothyrotomy).	

Modified from American Heart Association: *Basic life support for healthcare providers,* Dallas, 2010, The Association.

AIRWAY OBSTRUCTION IN A CONSCIOUS PATIENT

Meat is the most common cause of foreign body airway obstruction in conscious adults. (However, a variety of other foods and foreign objects is responsible for obstruction in children and in some adults.) Factors associated with choking include large, poorly chewed pieces of food, an elevated blood alcohol level, and poorly fitting dentures. The patient often is middle-aged or older.

CRITICAL THINKING

How can you relieve a foreign body airway obstruction using only your hands?

Foreign bodies may cause partial or complete airway obstruction. A patient with a partly obstructed airway usually can speak. The person usually can cough forcefully in an effort to expel the object. If air exchange is adequate, the rescuer should not intervene.[17] A patient with a partial obstruction should be monitored closely. The person should be encouraged to persist with spontaneous coughing and breathing efforts. If the obstruction persists or air exchange becomes severely compromised (evidenced by a silent cough, also wheezing, increased respiratory difficulty, decreased air movement, and cyanosis), the patient should be managed as though a complete airway obstruction existed.

Patients with complete airway obstruction cannot speak *(aphonia),* exchange air, or cough. They often grasp the neck between the thumb and fingers. (This is a universal sign of choking.) These patients need immediate rescuer intervention. Complete airway obstruction causes hypoxemia. It can lead to an acute myocardial infarction in patients with atherosclerotic cardiovascular disease. Airway obstruction inevitably leads to cardiac arrest in all patients if not corrected within minutes.

AIRWAY OBSTRUCTION IN AN UNCONSCIOUS PATIENT

Although upper airway obstruction may lead to loss of consciousness and cardiopulmonary arrest, more often the obstruction is caused by unconsciousness and cardiopulmonary arrest.[17] The primary source of upper airway obstruction in an unconscious patient is the tongue.

The tongue is attached to the mandible by the muscles that form the floor of the mouth. The normal tone of these muscles allows for air exchange by keeping the posterior pharynx open. If a patient is unconscious or has neuromuscular dysfunction, relaxation of these muscles may cause the airway to be blocked by the tongue. Airway obstruction by the tongue is common in the following situations:

- Cardiac arrest
- Trauma
- Stroke
- Intoxication with alcohol, barbiturates, or psychotropic drugs
- Paralysis caused by muscle relaxants
- Myasthenia gravis
- Fractured facial and nasal bones

SHOW ME THE EVIDENCE

Soroudi and colleagues performed a retrospective review of prehospital records for a 17-month period (2003 to 2005). They evaluated calls involving adult foreign body airway obstruction that were received by a California EMS service with a call volume of 250,000 per year. Of the 513 calls identified, 17 patients died. The mean patient age was 65 years. Meat and medications were the most common cause of obstruction. Performance of the Heimlich maneuver improved the patient's condition in 86.5% of cases. Direct laryngoscopy with use of Magill forceps was successful in three patients.

Soroudi A, Shipp H, Stepanski B, et al: Adult foreign body airway obstruction in the prehospital setting, *Prehosp Emerg Care* 11:25-29, 2007.

Laryngeal Spasm and Edema

Spasmodic closure of the vocal cords often is caused by an aggressive intubation technique. (Endotracheal intubation is discussed later in this chapter.) It also may occur during **extubation** (removal of the ET tube). This may be the case especially if the patient is semiconscious. Laryngeal spasm is best managed with aggressive ventilation and a forceful upward pull on the jaw. At times it may require the use of muscle relaxants. Maintaining steady pressure against the cords with the ET tube sometimes overcomes the spasmodic closure.

Swelling of the glottic and subglottic tissues of the airway can close off the larynx. The formation of edema may result from inflammatory or mechanical causes such as epiglottitis, croup, allergic reaction, thermal injuries, strangulation, blunt trauma, or drowning. Associated swelling may partly or completely obstruct the airway. Aggressive airway management (including the consideration for cricothyrotomy) is required for the patient's survival when this occurs.

Fractured Larynx

The most common cause of external trauma to the larynx is a motor vehicle crash. If a trauma patient has localized laryngeal pain on palpation or swallowing, stridor, hoarseness, difficulty with speech *(dysphonia),* or hemoptysis (coughing up blood), a fracture of the larynx should be suspected. Laryngeal injury can result in a lack of support for the vocal cords. This may cause them to collapse into the tracheal-laryngeal opening, obstructing the airway. Subcutaneous emphysema, dysphagia (difficult swallowing), and throat discomfort that increases with coughing or swallowing indicate the possibility of an impending airway obstruction as a result of a fracture. The paramedic should remain alert to the possibility of laryngeal fracture. This is important because laryngeal edema can rapidly close off the airway.

Certain types of injury may cause laryngeal fracture. Examples include a clothesline injury and blunt trauma to the neck. A laryngeal fracture requires rapid intervention. Cricothyrotomy may be required. The paramedic must secure an open airway before laryngeal edema and hemorrhage cause complete closure.

Tracheal Trauma

Trauma to the trachea is rare but serious. The most common site of tracheal injury is the area bordered by the cricoid cartilage and the third tracheal ring. This injury seldom occurs as an isolated event. More often it is associated with injuries to the surrounding esophagus and cervical spine. Central nervous system (CNS) injuries and abdominal and thoracic trauma also usually accompany tracheal injury. (Tracheal trauma is described in more detail in Chapter 40.)

ASPIRATION BY INHALATION

Aspiration is the active inhalation of food, a foreign body, or fluid (e.g., vomitus, saliva, blood, neutral liquids) into the airway. Depending on the type and degree of aspiration, the syndrome may cause spasm, mucus production, atelectasis, a change in pH (if the substance is acidic), or coughing. Prevention of aspiration is far superior to any known treatment. Aspiration is prevented mainly by controlling and maintaining the airway. Paramedics should always be prepared for the chance of aspiration in patients with a diminished level of consciousness.

About 80% of the approximately 3000 deaths each year from foreign body aspiration occur in children.[16] Running with food or other objects in the mouth, seizures, and forced feeding are among the risk factors in this age group. Hot dogs and peanuts are foods children commonly aspirate. In adults, obstruction may be caused by dental or nasal surgery, loss of consciousness, swallowing of poorly chewed food, and alcohol intoxication.

Large food particles and other foreign bodies can block the airway. This may cause hypoventilation of lower lung segments. The size of the particle determines which airway is obstructed and to what extent.

Approximately 60% of foreign bodies are found in the right mainstem bronchus, 19% in the left, and 21% at the larynx or vocal cords.[18] (The left mainstem bronchus branches from the trachea at a 45- to 60-degree angle. Thus foreign body occlusion of this bronchus is less likely than of the right mainstem bronchus, which is shorter, wider, and more vertical.) When the larynx or trachea is completely obstructed, the victim can die of asphyxiation within minutes.

The average adult stomach has a capacity of 1.4 L. It manufactures an additional 1.4 L of gastric juices in each 24-hour period. Hydrochloric acid is manufactured by special cells in the gastric mucosa. With the assistance of a protein-dissolving enzyme (pepsin), this acid helps break down large pieces of food into smaller ones.

Vomitus contains not only partly digested food particles but also acidic gastric fluid. Saliva is a watery, slightly acidic fluid. It is secreted in the mouth by the major salivary glands and the smaller salivary glands in the mucous membranes that line the mouth. Saliva contains the digestive enzyme amylase. This enzyme helps break down carbohydrates. Saliva also contains a number of other substances. These include minerals (e.g., sodium, calcium, and chloride), proteins, mucin (the principal constituent of mucus), urea, white blood cells, debris from the lining of the mouth, and bacteria.

The consequences of aspiration of neutral liquids (liquids that are neither acidic nor basic) are easier to reverse with supportive therapy than the consequences of aspiration of acids or bases. Nonetheless, aspiration of a large volume of neutral liquids also is associated with a high mortality rate.

Pathophysiology of Aspiration

Two conditions are associated with a high risk of aspiration: (1) a diminished level of consciousness and (2) mechanical disturbances of the airway and gastrointestinal (GI) tract.

A diminished level of consciousness may be caused by trauma, alcohol or other drug intoxication, a seizure disorder, cardiopulmonary arrest, a stroke, or a CNS dysfunction. The common element of these conditions is depression or loss of the gag reflex, with or without a full stomach. The **gag reflex** is a normal neural reflex triggered by touching the soft palate or posterior pharynx.

Iatrogenic obstructions (i.e., those caused by medical procedures) are a common type of mechanical obstruction. This type of obstruction results from the use of various devices to control upper airway problems. Examples include removal of certain airway devices (risk of vomiting on removal), placement of a nasogastric tube (the artificial opening through the esophageal sphincter increases the risk of regurgitation and aspiration), and intubation, which requires an adequate seal at the tracheal orifice to prevent aspiration. These mechanical airway devices are discussed later in this chapter.

Other mechanical or structural problems that may lead to a high risk of aspiration include tracheostomy and esophageal motility disorders, such as hiatal hernia and esophageal reflux. Other individuals at risk include those with intestinal obstructions and those fed by gastric tube.

The chance of aspiration increases whenever vomiting occurs. Vomiting follows stimulation of the vomiting center of the medulla. This stimulation can result from irritation anywhere along the GI tract, from information passed to the medulla from the frontal lobes of the brain, or from disturbances in the balance mechanism (vestibular system) of the inner ear. Once this center is stimulated, the following seven events occur:

1. A deep breath is taken.
2. The hyoid bone and larynx are elevated. This opens the preesophageal sphincter.
3. The opening of the larynx closes.
4. The soft palate is elevated, closing the posterior nares.
5. The diaphragm and the abdominal muscles contract forcefully. This compresses the stomach and increases the intragastric pressure.
6. The lower esophageal sphincter relaxes. The stomach contents are propelled into the lower esophagus.
7. If the patient is unconscious or unable to protect the airway, pulmonary aspiration may occur.

Effects of Pulmonary Aspiration

The severity of pulmonary aspiration depends on the pH of the aspirated material, the volume of the aspirate, and whether particulate matter (e.g., food) and bacterial contamination are present in the aspirate. It generally is accepted that severe pulmonary damage occurs when the pH of an aspirated material is 2.5 or lower. When the pH is below 1.5, the patient usually dies. The mortality rate among patients who aspirate grossly contaminated material (as occurs in bowel obstruction) approaches 100%.

The toxic effects on the lungs of gastric acid (which has a pH below 2.5) can be equated with those of chemical burns. These are severe injuries that produce pulmonary changes such as destruction of surfactant-producing alveolar cells, alveolar collapse and destruction, and destruction of pulmonary capillaries. The permeability of the capillaries increases with massive flooding of the alveoli and bronchi with fluid. The resulting pulmonary edema creates areas of hypoventilation, shunting, and severe hypoxemia. The massive fluid shift from the intravascular area to the lungs

also may produce hypovolemia severe enough to require volume replacement.

NOTE
The risk of pulmonary aspiration can be minimized by continuously monitoring the patient's mental status, properly positioning the patient to allow for drainage of secretions, limiting ventilatory pressures to prevent gastric distention, and using suction devices and esophageal or endotracheal (ET) intubation. Airway protection should be provided if the risk of aspiration exists. It also should be provided promptly after an occurrence of aspiration.

SECTION FOUR
Ventilation

ESSENTIAL PARAMETERS OF AIRWAY EVALUATION

Evaluation of the respiratory system is presented in depth in Chapter 20. This discussion is limited to essentials of airway evaluation that are used to identify immediate signs of life-threatening airway compromise. The essential parameters of airway evaluation are rate, regularity, and effort, in addition to recognition of airway problems that might indicate respiratory distress.

NOTE
This section serves as a review of techniques of airway assessment and airway management used by emergency medical responders (EMRs), emergency medical technicians (EMTs), and advanced emergency medical technicians (AEMTs). It also addresses advanced procedures used by paramedics.

Rate, Regularity, and Effort

The normal respiratory rate in a resting adult is 12 to 24 breaths/minute. Regularity is defined as a steady inspiratory and expiratory pattern. Breathing at rest should be effortless. It also should be marked by only subtle changes in rate or regularity.

Patients in respiratory distress often compensate for their inability to breathe easily by sitting upright with the head tilted back *(upright sniffing position),* by leaning forward on the arms *(tripod position),* or by lying down with the head and thorax slightly elevated *(semi-Fowler's position).* These patients frequently avoid lying flat, or supine.

CRITICAL THINKING
Why would lying flat on the back (i.e., in the supine position) most likely worsen respiratory distress?

Recognition of Airway Problems

Respiratory distress may be caused by upper or lower airway obstruction, inadequate ventilation, impairment of the respiratory muscles, ventilation/perfusion mismatching, diffusion abnormalities, or impairment of the nervous system. Dyspnea often is associated with hypoxia.

NOTE
Recognition and management of respiratory failure are crucial to the patient's survival. The brain can survive only a few minutes of anoxia. All therapies will fail if the airway is not adequate.

OBSERVATION TECHNIQUES

Visual clues can aid the recognition of airway problems. Paramedics should note the patient's preferred position to facilitate breathing. They also should assess the rise and fall of the patient's chest. Other visual clues to respiratory distress include the following:

- Gasping for air
- Cyanosis
- Nasal flaring
- Pursed-lip breathing
- Retraction of the intercostal or subcostal muscles, suprasternal notch, and supraclavicular fossa during respirations (Figure 15-27)

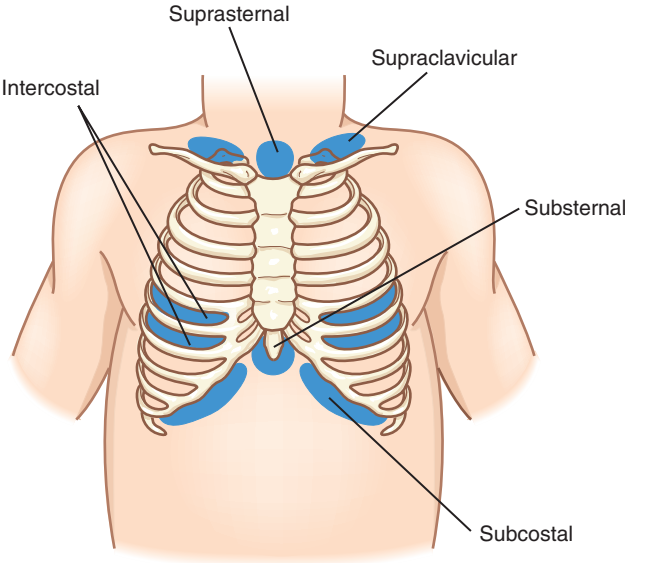

FIGURE 15-27 Areas of chest muscle retraction. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2009, Mosby.)

NOTE

Pulsus paradoxus is an exaggeration of the normal blood pressure variation that occurs with breathing. It is defined as a fall in systolic pressure of 10 mm Hg or more on spontaneous inspiration. At times it is associated with a change in the quality of the pulse. The condition occasionally is observed in patients with asthma or chronic obstructive pulmonary disease (COPD) and in victims of blunt or penetrating chest trauma (see Chapter 42). Pulsus paradoxus is difficult to measure. The paramedic should rely on more obvious signs and symptoms of respiratory distress.

AUSCULTATION, PALPATION, AND PERCUSSION TECHNIQUES

Air movement can be evaluated by listening to respirations without using a stethoscope (Figure 15-28) or by using a stethoscope to assess bilateral lung fields. Palpation of the chest wall helps determine the presence or absence of paradoxical (contrary) motion of the chest wall, inspiration, expiration, and any retraction of accessory muscles. Percussion may be helpful in some circumstances. This technique can be used to help determine the presence of air or blood in the chest cavity when diminished breath sounds or unequal chest wall movement is present (see Chapter 20).

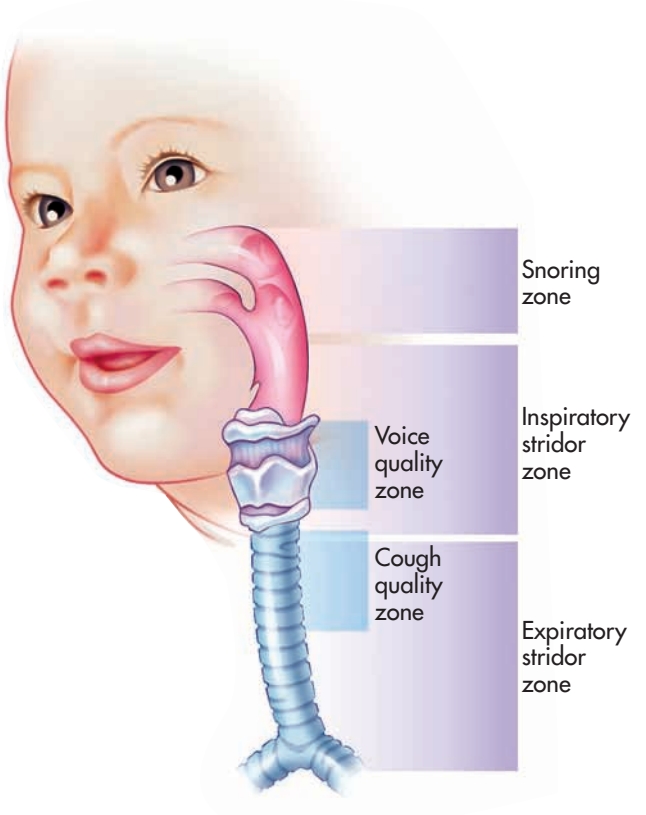

FIGURE 15-28 A loud, gasping snore suggests enlarged tonsils or adenoids. With inspiratory stridor, the airway is compromised at the level of the supraglottic larynx, vocal cords, subglottic region, or upper trachea. Expiratory stridor, or central wheeze, results from narrowing or collapse of the lower trachea or bronchi. Airway noise during both inspiration and expiration often represents a fixed obstruction of the vocal cords or subglottic space. Hoarseness or a weak cry is a byproduct of obstruction of the vocal cords. If a cough is croupy or low pitched, a tracheal disorder should be suspected. (McCance KL, Huether SE: *Pathophysiology: the biologic basis for disease in adults and children,* ed 6, St Louis, 2009, Mosby.)

OTHER SIGNS OF RESPIRATORY DISTRESS

Other signs that indicate possible causes of respiratory distress include resistance or changing compliance when assisting or delivering respirations with a bag-valve-mask (seen in asthma, chronic obstructive pulmonary disease [COPD], and tension pneumothorax), and the presence of pulsus paradoxus.

History

Obtaining a history to determine the progression and duration of the dyspneic event also helps guide the direction of patient care. For example, the paramedic should ask whether the event was sudden in onset or occurred over time. If it occurred over time, the length of that period should be determined. The paramedic also should ask whether any known causes or triggers initiated the difficulty breathing and if the respiratory distress is continuous or recurring. Other questions that should be asked in obtaining a patient's history include the following:

- What makes it better?
- What makes it worse?
- Do any other symptoms occur at the same time (e.g., cough, chest pain, fever)?
- Has any treatment with drugs been attempted?
- Has the patient taken all medications and treatments as prescribed?

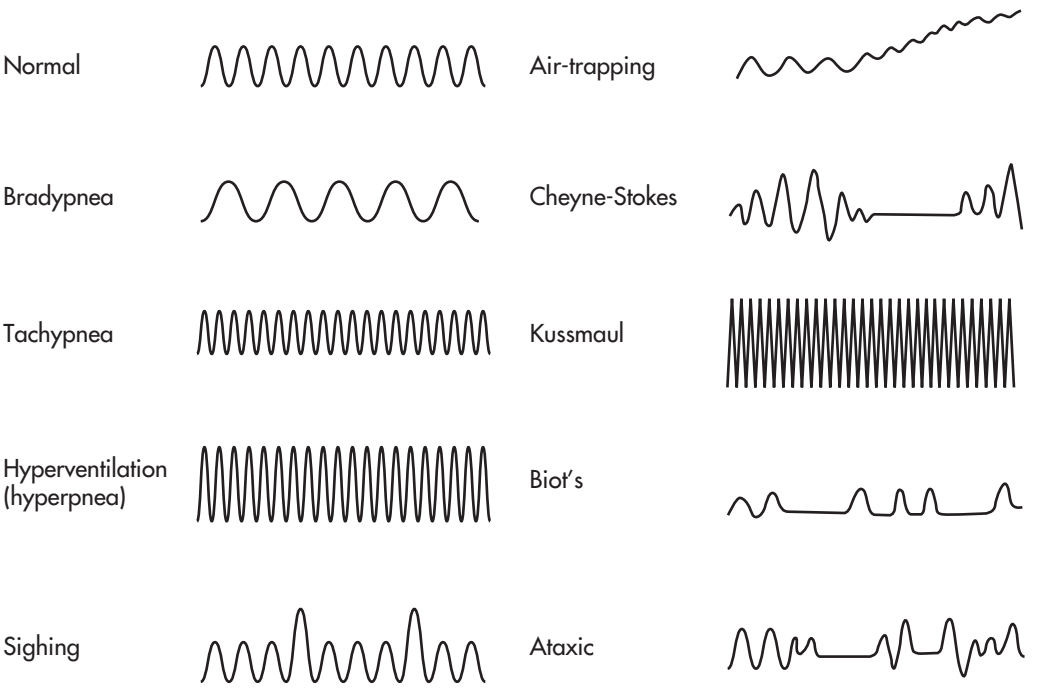
It also is crucial to determine whether the patient has been previously evaluated or hospitalized for this condition and whether the person has ever been intubated because of respiratory problems.

Changes in the Respiratory Pattern

As previously stated, the breathing process should be comfortable, regular, and performed without distress. Abnormal respiratory patterns are commonly seen in ill or injured patients (Figure 15-29 and Box 15-4). Recognizing these patterns may help paramedics determine the proper patient care.

Inadequate Respiration

Inadequate respiration can occur when the body cannot compensate for increased oxygen demand or cannot maintain a normal range of oxygen/carbon dioxide balance. Numerous factors can cause inadequate ventilation and respiration, including infection, trauma, brainstem injury, and a noxious or hypoxic atmosphere. A patient with respiratory compromise may have a number of symptoms and various respiratory rates and breathing patterns. Some medical experts distinguish between inadequate ventilation



Some influences on the rate and depth of breathing
The rate and depth of breathing will

Increase with	*Decrease with*
Acidosis (metabolic)	Alkalosis (metabolic)
Anxiety	Central nervous system lesions (cerebrum)
Aspirin poisoning	Myasthenia gravis
Oxygen need (hypoxemia)	Narcotic overdoses
Pain	Obesity (extreme)
Central nervous system lesions (pons)	

FIGURE 15-29 Patterns of respiration. The horizontal axis indicates the relative rate; the vertical swings indicate the relative depth.

caused by a problem in the mechanics of breathing (usually defined by the P_{CO_2}) and inadequate oxygenation but normal ventilation, as seen in pulmonary embolus and often pneumonia.

SUPPLEMENTAL OXYGEN THERAPY

Supplemental oxygen therapy may be provided for two reasons: (1) enriched oxygen in the atmosphere increases the oxygen content in pulmonary capillary blood; and (2) increasing the available oxygen allows the patient to compensate without increasing the work of breathing.

Oxygen Sources

The most common form of oxygen used in the prehospital setting is pure oxygen gas, delivered in liters per minute (LPM). This gas is stored under pressure in stainless steel or lightweight alloy cylinders (Figure 15-30). These cylinders have been color coded by the U.S. Pharmacopeia to distinguish various compressed gases. Steel green and white cylinders have been assigned to all grades of oxygen. Stainless steel and aluminum cylinders are not painted. Common sizes of oxygen cylinders (and their factors) used in emergency care include the following (Box 15-5):

Cylinder	Factor
D cylinder (425 L of oxygen)	0.16
Jumbo D cylinder (640 L of oxygen)	0.28
E cylinder (680 L of oxygen)	0.28
M cylinder (3450 L of oxygen)	1.56

Oxygen cylinders are filled under a pressure of 2000 to 2200 pounds per square inch (psi). Therefore, safety is critical when this equipment is handled. The paramedic should make sure the correct regulator is firmly attached before moving an oxygen cylinder. Also, a cylinder should never be

BOX 15-4 Abnormal Respiratory Patterns

Agonal respiration: A type of breathing that usually follows a pattern of gasping succeeded by apnea. It generally indicates the onset of respiratory arrest or the breathing pattern of a dying person.

Ataxic pattern: A type of cluster or irregular breathing pattern characterized by a series of inspirations and expirations. Ataxic respiration usually is associated with a structural or compressive lesion in the medullary respiratory centers.

Biot pattern: A respiratory pattern involving irregular respirations varying in depth and interrupted by intervals of apnea (absence of breathing). Although similar to Cheyne-Stokes respiration, this pattern lacks the repetitiveness of that type and often is irregular. Biot respiration usually is seen in patients with head injuries who have increased intracranial pressure. Unlike Cheyne-Stokes respiration, the Biot ataxic pattern frequently produces ventilatory failure and may lead to apnea.

Bradypnea: A persistent respiratory rate slower than 12 breaths/minute. This abnormal rate may be a result of the patient guarding against respiratory discomfort caused by chest wall injury, respiratory failure, cerebrovascular accident (CVA), pulmonary infection, or narcotic poisoning. However, bradypnea is more commonly caused by respiratory drive depression that occurs secondary to neurological disturbances.

Central neurogenic hyperventilation: A pattern of breathing marked by rapid and regular ventilations at a rate of about 25 breaths/minute. Increasing regularity, rather than rate, is an important diagnostic sign, because it indicates an increasing depth of coma.

Cheyne-Stokes respiration: A regular, periodic pattern of breathing with equal intervals of apnea followed by a crescendo-decrescendo sequence of respirations. Cheyne-Stokes respirations are thought to represent a level of cortical dysfunction of the brain. Although some children and older adults breathe in this pattern during sleep, it is usually seen in patients who are seriously ill or injured.

Eupnea: Normal breathing.

Hyperventilation: A persistent, rapid, deep respiration that often results in hyperpnea. Compared with tachypnea, hyperpnea usually is slower and much deeper. Its causes include exercise, anxiety, metabolic disturbances (e.g., diabetic ketoacidosis), and central nervous system illness.

Kussmaul respiration: An abnormally deep, very rapid sighing respiratory pattern characteristic of diabetic ketoacidosis or other metabolic acidosis.

Tachypnea: A persistent respiratory rate that exceeds 20 breaths/minute. It may be common in patients who are in pain, frightened, or anxious. The many other causes of tachypnea include fractured ribs, pneumonia, pneumothorax, pulmonary embolus, and pleurisy.

FIGURE 15-30 Oxygen cylinders: M, E, jumbo D, and D.

BOX 15-5 Calculating Oxygen Tank Life

This method can be used to estimate the amount of oxygen available in an oxygen cylinder. First, subtract the safe residual pressure (200 psi) from the tank pressure. Second, multiply the result by the tank's factor (cylinder constant). This equals the volume of gas. Third, divide the volume of gas by the liters per minute (LPM) delivery. This equals the tank life in minutes.

Example

The tank pressure in an E cylinder is 650 psi. You are delivering 6 L/minute of oxygen to the patient.

Step **1**. Subtract the safe residual pressure from the tank's psi:

$$650 - 200 = 450$$

Step **2**. Multiply the result by the E cylinder factor to obtain the volume of gas:

$$450 \times 0.28 = 126$$

Step **3**. Divide the volume of gas by the LPM delivery to determine the tank life in minutes:

$$126 \div 6 = 21 \text{ minutes}$$

handled by the neck assembly alone. Most oxygen cylinders are considered "empty" at 200 psi. (This is the safe residual pressure.) As a rule, tanks with less than 500 psi are too low to keep in service.

LIQUID OXYGEN

Liquid oxygen (LOX) has been cooled to its aqueous state. However, it converts to a gaseous state when warmed. The liquid form is used by some air medical services and by other EMS agencies when the weight and space that a standard oxygen system occupies must be considered. The main advantage of liquid oxygen is that a much larger volume of gaseous oxygen can be stored in an aqueous state. One disadvantage of liquid oxygen is the cost. (LOX is more expensive than pressurized oxygen.) Another is the fact that the units generally require upright storage. Finally, special requirements are necessary for large-volume storage and cylinder transfer.

REGULATORS

High-pressure regulators are used to transfer cylinder gas from tank to tank. They are attached to cylinder stems and allow cylinder gas to be delivered under high pressure. *Therapy regulators* are used to deliver a safe pressure of oxygen to patients (Figure 15-31). They are attached to the cylinder stem. Therapy regulators work through a regulator mechanism whereby 50 psi escape pressure is reduced ("stepped down") to 30 psi for safe delivery to the patient.

NOTE
Therapy regulators (used for delivery of oxygen to patients) are attached to smaller oxygen cylinders by a yoke assembly with a pin index safety system. This system prevents the paramedic from using a regulator with the wrong type of gas. It requires that the yoke pins match the corresponding holes in the valve assembly for oxygen to be delivered. Larger oxygen cylinders have valve assemblies with a threaded outlet specific to medical oxygen.

FLOWMETERS

Flowmeters control the amount of oxygen delivered to the patient (Figure 15-32). These devices are connected to the pressure regulator. They are adjusted to deliver oxygen at a set number of liters per minute. Some EMS agencies attach disposable humidifiers to the flowmeter. This provides moisture to the dry oxygen coming from the supply cylinder. Humidified oxygen is desirable for long-term oxygen administration and for patients with croup, epiglottitis, or bronchiolitis (see Chapter 24).

Oxygen Delivery Devices

Patients who have spontaneous respirations can receive supplemental oxygen through several different oxygen delivery devices. These include a nasal cannula, simple face mask, partial rebreather mask, nonrebreather mask, and Venturi mask (Table 15-4). Each of these devices has advantages and disadvantages.

NASAL CANNULA

The nasal cannula (Figure 15-33) delivers low-concentration oxygen through two small plastic prongs placed into the nostrils. Nasal cannulas should not be used in patients with poor respiratory effort, severe hypoxia, or apnea. They also should not be used in patients who breathe primarily through the mouth. As a rule, the nasal cannula is well

TABLE 15-4 Oxygen Delivery Devices

Device	Flow Rate (L/min)	Oxygen (O_2)% Delivered
Nasal cannula	1-6	24-44
Simple face mask	6-10	35-60
Partial rebreather mask	6-10	35-60
Nonrebreather mask	10-15	80-95
Venturi mask	4-8	24-50

TABLE 15-5 Approximate Oxygen Concentration for Liters Per Minute Flow

Liters Per Minute	Oxygen Concentration
1	24%
2	28%
3	32%
4	36%
5	40%
6	44%

tolerated. However, it does not deliver high-volume/high-concentration oxygen. The relationship of approximate oxygen concentrations to liter per minute flow is listed in Table 15-5.

Obtaining oxygen concentrations greater than 30% to 35% is difficult with a nasal cannula. This is because the patient continues to breathe through the mouth during oxygen administration. The mouth breathing reduces the concentration of oxygen inspired through the nose. The device also is ineffective if the patient's nose is blocked by blood or mucus. For these reasons, use of the nasal cannula is limited to patients who would benefit from low-concentration oxygen delivery. This may include some patients with chest pain and patients with chronic pulmonary disease. The maximum oxygen flow rate for a nasal cannula is 6 L/min.

SIMPLE FACE MASK

The simple face mask (Figure 15-34) is a soft, clear plastic mask that conforms to the patient's face. Small perforations in the mask allow atmospheric gas to be mixed with oxygen during inhalation. They also permit the patient's exhaled air to escape. Oxygen concentrations of 35% to 60% can be delivered through this device with a flow rate of 6 to 10 L/min. A flow rate of less than 6 L/minute can produce an accumulation of carbon dioxide in the mask; therefore, oxygen delivery through any face mask should always exceed this minimum. Flow rates above 10 L/minute do not enhance oxygen concentration. All masks must be well fitted to the patient's face for optimal benefit. Leaks reduce the oxygen concentration.

FIGURE 15-34 Simple face mask.

FIGURE 15-35 Partial rebreather mask.

PARTIAL REBREATHER MASK

The partial rebreather mask (Figure 15-35) has an attached oxygen reservoir bag. The bag should be filled before the patient uses the mask. This device has vent ports covered by one-way disks. These allow a portion of the patient's exhaled gas to enter the reservoir bag and be reused. The remainder of the carbon dioxide–loaded gas escapes into the atmosphere. Oxygen concentrations of 35% to 60% can be delivered with a flow rate that prevents the reservoir bag from collapsing completely on inspiration. Partial rebreather masks should not be used in patients with apnea or poor respiratory effort. As with the simple face mask, delivery of volumes above 10 L/minute with this device does not enhance oxygen concentration.

NONREBREATHER MASK

The nonrebreather mask (Figure 15-36) is similar in design to the partial nonrebreather mask. However, a flutter valve assembly in the mask piece stops the patient's exhaled air

FIGURE 15-36 Nonrebreather mask.

FIGURE 15-37 Venturi mask.

from returning to the reservoir bag. This device delivers oxygen concentrations up to and above 95%. The flow rate must be adequate to keep the reservoir bag partly inflated during inspiration. (Patients with severe respiratory distress may need up to 20 L/minute to maintain inflation of the reservoir bag.) Paramedics should make sure the mask is seated firmly over the patient's mouth and nose. They also should make sure the reservoir bag is never less than two-thirds full. This device most often is used in patients who need high-concentration oxygen delivery (10 to 15 L/minute). As with other masks, it should not be used in patients with apnea or poor respiratory effort.

CRITICAL THINKING
What could happen if the oxygen source is disconnected from a nonrebreather mask?

VENTURI MASK

The Venturi mask (Figure 15-37) is a high-airflow oxygen entrainment delivery device. It delivers a precise fraction of inspired oxygen (FiO_2) at typically low concentrations. The device originally was designed to deliver 30% to 40% concentrations. However, it since has been adapted to deliver higher oxygen percentages. The Venturi mask uses "jet mixing" of atmospheric gas and oxygen to achieve the desired mixture.

Color-coded adapters in various sizes are attached to the mask to control the oxygen flow rate. (Standard-size adapters are 3, 4, and 6 L/minute.) The color codes and adapters state the exact liter flow to use to obtain the precise FiO_2. Choosing a different liter flow greatly alters the FiO_2 delivered. The various Venturi masks deliver 24% to 50% oxygen. They are advised for patients who rely on a hypoxic respiratory drive. This includes, for example, patients with COPD. The main benefit of the Venturi mask is that it allows precise regulation of the FiO_2. It also permits the paramedic to titrate oxygen for the patient with COPD so as not to exceed the patient's hypoxic drive while allowing enrichment of supplemental oxygen. Care must be taken to match the proper FiO_2 to the correct flow rate. Otherwise, the Venturi mask does not deliver the indicated FiO_2.

AUGMENTING PATIENT VENTILATIONS

Some patients who have spontaneous breathing but who also have dyspnea or respiratory compromise need assistance to improve airflow and oxygenation. Methods to improve a patient's arterial oxygenation include continuous positive airway pressure (CPAP) and biphasic positive airway pressure (BiPAP). CPAP and BiPAP can improve oxygenation through positive pressure during spontaneous breathing, reduce the work of breathing, prevent atelectasis, and allow for drug administration. These methods also may prevent the need for intubation and the risks and complications associated with invasive airway procedures. Indications and contraindications for CPAP and BiPAP are presented in Box 15-6.

Continuous Positive Airway Pressure

Continuous positive airway pressure (CPAP) transmits positive pressure into the airways of a spontaneously breathing patient throughout the respiratory cycle. The increase in airway pressure allows for better diffusion of gases and reexpansion of collapsed alveoli. This results in improvement of gas exchange and a reduction in the work of breathing. CPAP can be applied invasively in a patient with spontaneous breathing (through an ET tube). It also can be applied noninvasively through a face or nose mask. Mask CPAP is provided through a tight-fitting face mask that is connected to a battery-operated or oxygen-driven breathing circuit. This breathing circuit may have a fixed or an adjustable FiO_2 and a fixed or an adjustable pressure valve that delivers pressures of 5 to 10 cm H_2O or more

BOX 15-6 Indications and Contraindications for CPAP and BiPAP

Indications

Acute respiratory distress syndrome (ARDS)
Asthma
Chronic obstructive pulmonary disease (COPD)
Congestive heart failure (CHF)
Pneumonia
Pulmonary edema
Submersion (near-drowning) incidents

Contraindications

Patients who are unconscious
Children under 14 years of age
Upper airway trauma
Hypotension or shock
Facial/chest trauma
Pneumothorax
Barotrauma
Inability to breathe spontaneously
Inability to maintain mask seal
Stoma or tracheotomy
Serious dysrhythmias
Nausea or vomiting
Gastrointestinal (GI) bleeding or recent GI surgery

(Figure 15-38). (A normal protocol for most EM services is 7 to 10 cm H_2O.)

NOTE

Continuous positive airway pressure (CPAP) is generally well tolerated by patients. However, CPAP may have adverse effects on the circulation or pulmonary system, especially at higher pressures. Such effects include decreased venous return, decreased cardiac output, and pulmonary barotrauma. All patients should be closely monitored for signs and symptoms of adverse effects. If CPAP is used, start with low pressures (5 to 7.5 cm H_2O) and increase in increments of 2 cm H_2O as tolerated by the patient. Respiratory goals may include an exhaled tidal volume greater than 7 mL/kg, a respiratory rate of less than 25, oxygen saturation greater than 90%, and perhaps most important, patient comfort.[19]

CPAP lowers the mean airway pressure. In addition to its use in patients with pulmonary edema, CPAP also may benefit patients with obstructive airway disease.[3] (Nasal CPAP is used in the home for patients with a history of sleep apnea.) Patients who receive CPAP usually are quite anxious. About 5 minutes after the mask is applied, the patient should be observed for signs and symptoms of improvement. These include reduced effort of breathing, increased ease in speaking, slowing respiratory and heart rate, and increased PaO_2. The patient is likely to require

FIGURE 15-38 CPAP machine.

extensive coaching and reassurance from the paramedic. Use of CPAP with standard drug therapy to treat pulmonary edema has been shown to reduce the need for intubation.[21] (Early hospital notification allows for CPAP to be available on arrival at the emergency department [ED].)

SHOW ME THE EVIDENCE

From 2002 to 2006, Thompson and coworkers compared the outcomes for 71 patients in severe respiratory distress who had no chest pain. Two groups were randomized for treatment, either with standard care or with standard care and continuous positive airway pressure (CPAP). The researchers found that patients treated with CPAP were less likely to require endotracheal intubation and less likely to die.

Thompson J et al: Out-of-hospital continuous positive airway pressure ventilation versus usual care in acute respiratory failure: a randomized controlled trial, *Ann Emerg Med* 52:232-241, 2008.

BIPHASIC POSITIVE AIRWAY PRESSURE

Biphasic positive airway pressure (BiPAP), also known as *bi-level positive airway pressure,* combines partial ventilatory support and CPAP. This allows the pressure to vary during each breath cycle. When the patient inhales, the pressure is similar to CPAP. When the patient exhales, the pressure drops, making it easier to breathe. BiPAP is applied by face mask or nose mask through a noninvasive ventilator device with two settings (Figure 15-39). The device provides a 5 cm H_2O pressure difference between *inspiratory positive airway pressure (IPAP)* and *expiratory positive airway pressure (EPAP).* BiPAP is a leak-tolerant system; that is, the unit can respond and adjust to leaks. CPAP is not a leak-tolerant system. It allows IPAP and EPAP settings to be titrated (adjusted) to reach a desired range of positive end-expiratory pressure (described later). In selected patients with

FIGURE 15-39 BiPAP machine. (Shade BR et al: *Mosby's EMT-Intermediate textbook for the 1999 National Standard Curriculum,* ed 3, St Louis, 2007, Mosby.)

respiratory distress caused by COPD, pulmonary edema, pneumonia, or asthma, BiPAP may eliminate the need for endotracheal intubation.

NOTE

With biphasic positive airway pressure (BiPAP), the inspiratory positive airway pressure (IPAP) setting may range from 4 to 24 cm H_2O, and the expiratory positive airway pressure (EPAP) setting may vary from 2 to 20 cm H_2O. Typical initial settings for BiPAP are 8 to 10 cm H_2O IPAP and 2 to 4 cm H_2O EPAP. These settings presume that the lower pressures allow patient tolerance and training. When using BiPAP, the paramedic should remember that the inspiratory pressure must be maintained higher than the expiratory pressure at all times to ensure biphasic flow. In addition, the flow must be synchronized with the patient's respiratory efforts.[22]

PROCEDURE FOR ADMINISTERING CONTINUOUS POSITIVE AIRWAY PRESSURE

Methods for delivering continuous positive airway pressure vary by device and by the manufacturer's guidelines. The following are general guidelines.

1. Treat the patient's underlying conditions as needed.
2. Assess for indications and contraindications.
3. Place the patient in a sitting position or similar position of comfort.
4. Assess vital signs and lung sounds before and during therapy. (The systolic pressure should be above 90 mm Hg.) Vital signs should be assessed every 5 minutes.
5. Attach an electrocardiograph (ECG) and pulse oximeter.

FIGURE 15-40 PEEP valve.

6. Explain the procedure to the patient.
7. Anticipate and control anxiety (consider sedation with benzodiazepines, per protocol).
8. Provide coaching as needed.
9. Connect CPAP to oxygen source; begin CPAP pressure at 5 to 7.5 cm H_2O.
10. Apply the mask and check for air leaks. Use head straps if needed and if tolerated by the patient.
11. Administer nebulized medications as indicated.
12. Treatment should be given continuously throughout transport to the ED. (CPAP therapy should be continued until arrival in the ED.) CPAP may be stopped if the patient cannot tolerate the mask; if the airway requires suctioning or intervention; if respiratory distress worsens; or if a pneumothorax is suspected.

Note: Intermittent positive pressure ventilation and/or intubation should be considered if the patient is removed from CPAP therapy in the prehospital setting. Some patients require intubation in the prehospital setting even with CPAP therapy. Intubation should be considered with:

- Deterioration of mental status
- Increase in $EtCO_2$
- Decrease in SpO_2
- Progressive fatigue
- Ineffective tidal volume
- Respiratory or cardiac arrest

POSITIVE END-EXPIRATORY PRESSURE

As do CPAP and BiPAP, **positive end-expiratory pressure (PEEP)** maintains a degree of positive pressure at the end of exhalation. PEEP is given to patients who have been intubated and who are receiving mechanical ventilation. (PEEP is considered an invasive procedure.) Positive pressure at the end of exhalation keeps the alveoli open and pushes fluid from the alveoli back into the interstitium or capillaries.

In the prehospital setting, ventilatory support with PEEP can be provided through a PEEP valve. These valves are hollow cylinders that have a weight in the lumen (e.g., a Boehringer valve or other special PEEP delivery device) (Figure 15-40). The PEEP device is connected to the expiratory port of a bag-valve device. The valve is available in pressures of 5, 10, and 15 cm H_2O. It creates PEEP by forcing the patient to exhale against the weight of the metal ball. Some transport ventilators have built-in PEEP controls.

RESCUE BREATHING AND MECHANICAL VENTILATION

Ventilation of a patient can be provided by several methods in the prehospital setting. These include rescue breathing (mouth to mouth, mouth to nose, mouth to stoma), mouth-to-mask breathing, bag-mask devices, and automatic transport ventilators. The following discussion of ventilation methods follows the recommendations of the American Heart Association.[23]

NOTE
Providing ventilations with barrier protection should always be a priority when performing rescue breathing. Even so, mouth-to-mouth, mouth-to-nose, and mouth-to-stoma ventilations are presented here for a complete discussion.

Rescue Breathing

As discussed previously, inspired air has an oxygen concentration of about 21%. Of this 21%, about 4% is used by the body. The remaining 17% is exhaled. Ventilation by rescue breathing can provide adequate oxygenation to a patient with respiratory insufficiency.

Rescue breathing has some advantages: no equipment is needed, and it is immediately available. However, it also has disadvantages. One disadvantage is the limitation of the vital capacity of the rescuer. (About 500 to 600 mL is needed to ventilate an adult.) Another drawback is the low amount of oxygen delivered in expired air compared with other methods of ventilation with supplemental oxygen. Also, a rescuer may have difficulty forcing air past any obstructions in the airway. Transmission of a disease through direct body fluid contact is a risk. Another risk is the transmission of an unknown communicable disease at the time of the event. Complications common to all rescue breathing techniques include the following:

- Hyperinflation of the patient's lungs
- Gastric distention
- Blood/body fluid contact concerns
- Rescuer hyperventilation

NOTE
Rescuer hyperventilation is also known as **inadvertent hyperventilation.** This commonly occurs during the delivery of cardiopulmonary resuscitation (CPR) when a patient in cardiac arrest is ventilated excessively. Excessive ventilation is thought to result in increased intrathoracic pressure that causes decreased venous return and decreased coronary perfusion pressure. Rescuer hyperventilation is believed to have a negative effect on survival rates for patients who have suffered cardiac arrest[24] (see Chapter 22). Impedance threshold devices (ITDs) with pressure-sensitive valves are available to limit the influx of air during chest wall compressions. The ITD also lowers intracranial pressure during the decompression phase of CPR. This, combined with increased cardiac output, may result in greater cerebral perfusion.[25] Studies, however, have yet to determine the relative contribution of the ITD to improved outcome.[23]

CRITICAL THINKING
What are two harmful effects of gastric distention during artificial ventilation?

MOUTH-TO-MOUTH METHOD

Paramedics should use the following guidelines in delivering ventilations mouth to mouth:

1. If no spinal injury is suspected, position the patient with optimum head tilt and chin lift. (If a spinal injury is suspected, maintain in-line stabilization and keep the airway open through the jaw-thrust maneuver without the head-tilt technique [described later in this chapter].) If this technique does not open the airway, use the head-tilt chin-lift maneuver. If necessary, clear the airway of vomitus, body fluids, and foreign objects.
2. Pinch the patient's nostrils closed.
3. Inhale a normal breath.
4. Seal your mouth over the patient's mouth, which should be slightly open.
5. Exhale into the patient's mouth over 1 second, until the chest rises visibly.
   Each adult ventilation is about 500 to 600 mL of air.
6. Break contact with patient's mouth and inhale another normal breath.
7. Deliver another breath (as described in step 5).
8. Continue rescue breathing at a rate of 10 to 12 breaths/minute (1 breath every 5 to 6 seconds) as needed. If an advanced airway is placed, reduce the rate to 8 to 10 breaths/minute (1 breath every 6 to 8 seconds).

Mouth-to-mouth breathing usually results in the exchange of saliva between the victim and the rescuer. Transmission of the hepatitis B virus (HBV) and the human immunodeficiency virus (HIV) during rescue breathing has not been documented. However, rare instances of herpes transmission during cardiopulmonary resuscitation (CPR) have been reported.[17] When possible, personal barrier protection devices should be used.

MOUTH-TO-NOSE METHOD

Mouth-to-nose ventilation is very similar to the technique described for mouth-to-mouth rescue breathing. The differences in the mouth-to-nose method are as follows:

- If no spinal injury is suspected, the rescuer must keep one hand on the patient's forehead to maintain an open airway while using the other hand to close the patient's mouth. (If a spinal injury is suspected, the jaw-thrust without head-tilt technique should be used. The rescuer's cheek is used to seal the patient's mouth.)
- The patient's nose is left open.
- The rescuer's mouth is placed over the patient's nose with as tight a seal as possible.
- During passive exhalation by the patient, the rescuer's mouth is removed from the patient's nose and the

patient's mouth is opened for exhalation. The head-tilt or jaw-thrust position must be maintained to ensure an open airway.

Mouth-to-nose ventilation may be appropriate for patients who have injuries to the mouth and lower jaw and for patients with missing teeth or dentures (which makes a tight seal around the mouth difficult). It also may overcome psychological barriers in having mouth-to-mouth contact with a patient.

VENTILATION OF INFANTS AND CHILDREN

To provide ventilations to infants and children, the paramedic should use the mouth-to-mouth-and-nose technique:

1. Position the patient with a *slight* head tilt and chin lift sufficient to open the airway. Hyperextension of a pediatric patient's neck may block the airway. (Use spinal precautions as needed [see Chapter 41]).
2. During ventilation, the rescuer's mouth should cover both the mouth and nose of the infant or small child up to 1 year of age.
3. Exhale into the patient's mouth until the chest rises.
4. When allowing for passive exhalation, break contact with the patient's mouth and nose.
5. Provide ventilations at a rate of 12 to 20 breaths/minute (1 breath every 3 to 5 seconds). When an advanced airway has been placed, reduce the rate to 8 to 10 breaths/minute (1 breath every 6 to 8 seconds).
6. Deliver each breath over 1 second.
7. Make sure the chest rises.

MOUTH-TO-STOMA METHOD

A *stoma* is a temporary or permanent surgical opening in the neck of a patient who has had a laryngectomy or tracheostomy (Figure 15-41). The airway of such a patient has been surgically interrupted. The larynx is no longer connected to the trachea (Box 15-7).

The stoma created by a laryngectomy is large and round; the edge of the tracheal lining can be seen attached to the skin. The stoma in tracheostomy patients usually is no more than several millimeters in diameter. It usually contains one or two concentric tubes (one fitting inside the other) made of plastic or metal. The method of ventilating these patients is the same, regardless of the type of stoma.

Stomas and breathing tubes may become clogged with secretions, encrusted mucus, and foreign matter, leading to inadequate ventilation. If cleaning is needed, wipe the neck opening with gauze. If the breathing tubes are clogged, they can be removed or suctioned. The tracheostomy tube or stoma is suctioned by passing a sterile suction catheter through the external opening into the trachea. *Do not insert the catheter more than 7 to 12 cm (3 to 5 inches) into the trachea.* Once the airway is partly open, begin ventilations by the mouth-to-stoma method (mouth-to-stoma ventilation is bacteriologically cleaner than the mouth-to-mouth method) by using a pediatric-size pocket mask over the top

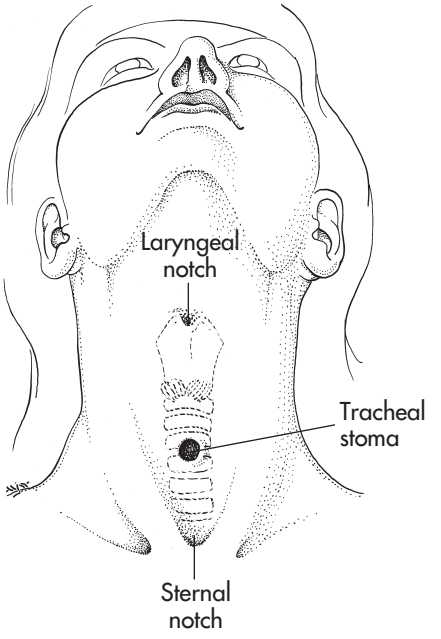

FIGURE 15-41 Stoma.

BOX 15-7 Special Considerations for Patients Who Have Had a Laryngectomy

When providing care for a patient who has had a laryngectomy, paramedics sometimes may need to suction the tracheostomy tube or remove, clean, and replace a tube that has become obstructed by mucus. (Patients who have had a laryngectomy have a less effective cough. As a result, mucous plugs often obstruct breathing tubes.)

The steps for suctioning a breathing tube are as follows:

1. Preoxygenate the patient.
2. Inject 3 mL of sterile saline down the trachea.
3. Step 2 usually results in coughing. If it does not, instruct the patient to exhale.
4. Insert the suction catheter into the trachea until resistance is met (without negative pressure).
5. Step 4 usually results in coughing. If it does not, instruct the patient to cough or exhale.
6. Suction while withdrawing the catheter.

If the breathing tube cannot be cleared and requires replacement, follow these steps:

1. Lubricate a same-size tracheostomy tube or endotracheal (ET) tube (5 mm or larger).
2. Instruct the patient to exhale.
3. Gently insert the tube 1 to 2 cm (about ½ to ¾ inch) beyond the balloon cuff.
4. Inflate the cuff.
5. Confirm the patient's comfort and verify the patency and proper placement of the tube.

Stenosis (spontaneous narrowing of a stoma) may be life-threatening. It also makes replacing a tracheostomy tube difficult or impossible. When stenosis is a factor, an ET tube must be placed before total obstruction occurs.

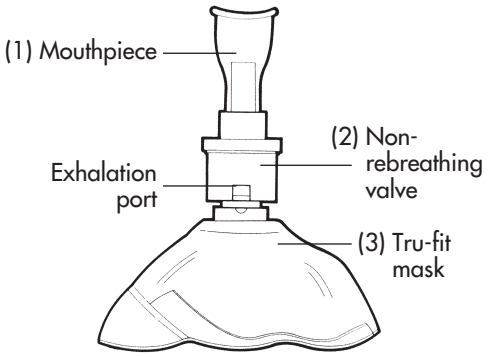

FIGURE 15-42 Mouth-to-mask device.

of the stoma or by securing the airway with an ET tube placed through the stoma.

The technique for stoma ventilation is basically the same as that for other methods of artificial ventilation. However, the patient's head should be kept straight (rather than tilted back), with the shoulders slightly elevated. This position allows more effective ventilation. If the patient's chest does not rise or if air is heard to escape through the patient's upper airway, the patient may be a "partial neck breather." These patients are able to inhale and exhale some air through their nose and mouth. If this occurs, the patient's nostrils must be pinched closed and the mouth sealed with the palm of one hand during ventilation.

Mouth-to-Mask Devices

Mouth-to-mask devices have become popular. They are used as an alternative to mouth-to-mouth methods of ventilation. These masks are constructed of a clear, flexible material. They are available with one-way valves, bacterial filters, and ports for supplemental oxygen delivery (Figure 15-42). They are made by a number of manufacturers and are available in a variety of sizes. The mouth-to-mask technique offers several advantages:

- It eliminates direct contact with the patient's mouth and nose.
- It provides more effective ventilation than the mouth-to-mouth method or a bag-valve-mask device.
- It reduces the risk of disease transmission.
- It allows delivery of supplemental oxygen.
- The one-way valve eliminates exposure to exhaled gases and sputum.
- The mask is easy to apply.

TECHNIQUE

The mask device can be used in patients with or without spontaneous respirations (Figure 15-43). To apply the mask, the paramedic should follow these steps:

1. If no spinal injury is suspected, position the patient with optimum head tilt and chin lift. Use an oropharyngeal or a nasopharyngeal airway if the patient is unconscious. (If a spinal injury is suspected, spinal precautions should be followed.)

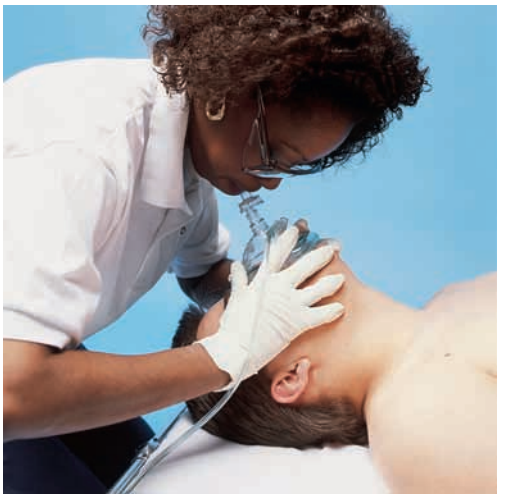

FIGURE 15-43 Mouth-to-mask ventilation technique (cephalic technique).

2. Connect the one-way valve to the mask. Oxygen tubing should be connected to the inlet port with an oxygen flow rate of 10 to 12 L/minute. Using supplemental oxygen provides a higher concentration of oxygen in the inspired air. An oxygen flow rate of 10 L/minute, combined with rescuer ventilations, can supply an oxygen concentration of 50%.
3. Position yourself at the patient's head (cephalic technique) or side (lateral technique). Clear the airway of secretions, vomitus, and foreign objects. Place the mask on the patient's face and create an airtight seal. Using the thumb side of the palm with both hands, apply pressure to the sides of the mask. If using the cephalic technique, apply upward pressure to the mandible just in front of the earlobes, using the index, middle, and ring fingers of both hands while maintaining head tilt. If using the lateral technique, seal the mask by placing the index finger and thumb of the hand closer to the top of the patient's head along the border of the mask and place the thumb of the other hand along the lower margin of the mask. Place the remaining fingers of the hand closer to the patient's feet and lift the jaw while performing a head-tilt chin-lift.
4. Blow into the opening of the mask, observing chest rise and fall. If available, a second rescuer may apply cricoid pressure (Box 15-8). Cricoid pressure may help prevent gastric inflation during positive pressure ventilation and reduce the chance of regurgitation and aspiration.
5. Remove the mask from the patient's face to allow for passive exhalation.

If oxygen is not available, the tidal volumes and inspiratory times for mouth-to-mask ventilation should be the same as for mouth-to-mouth breathing, assuring visible chest rise. If supplemental oxygen is used with the face mask, provide a minimum flow rate of 10 to 12 L/minute.

BOX 15-8 Application of Cricoid Pressure

Applying pressure to the solid ring of the cricoid cartilage (Sellick maneuver) can occlude the esophagus and may reduce the risk of regurgitation and aspiration. This type of pressure also can help minimize gastric distention during bag-mask ventilation, and may improve visualization of the vocal cords during intubation. Studies suggest that cricoid pressure can interfere with effective ventilation. It is no longer recommended for routine use during ventilation during adult cardiac arrest.[23]

Cricoid pressure should be used with caution if a cervical spine injury is suspected, because it may cause additional damage to the spine. Complications include laryngeal trauma with excessive force and esophageal rupture from unrelieved high gastric pressures.

FIGURE 15-44 Disposable and reusable adult and pediatric bag-mask devices.

Bag-Mask Devices

Bag-mask devices consist of a self-inflating bag and a nonrebreathing valve (Figure 15-44). They can be used with a mask, an ET tube, or another invasive airway device. An adequate bag-valve unit should have the following components:

1. A self-refilling bag that is disposable or easily cleaned or sterilized
2. A nonjam valve system that allows a minimum oxygen inlet flow of 15 L/minute
3. A non-pop-off valve
4. Standard 15 and 22 mm fittings
5. A system for delivering high-concentration oxygen through an inlet port at the back of the bag or by an oxygen reservoir
6. A nonrebreathing valve.[26]

The device also should perform in all common environmental conditions and under extremes of temperature. It should be available in both adult and pediatric sizes. The mask should be clear to detect vomiting early.

NOTE
All paramedics should be proficient in delivering effective oxygenation and ventilation with a bag-mask device to adults, children, and infants. This is the preferred method of ventilatory support, particularly if the transport time is short.[23]

When the bag-mask device is compressed, air is delivered to the patient through a one-way valve. The air inlet to the bag is closed during delivery. When the bag is released, the patient's expired gas passes through an exhalation valve into the atmosphere. This prevents the patient's exhaled air from reentering the bag-mask device. As the patient exhales, atmospheric air and supplemental oxygen from the reservoir refill the bag.

Use of the bag-mask device with a mask is difficult because of the problem of creating an effective seal between the mask and the patient's face while maintaining an open airway. For this reason, it has been recommended that two rescuers use the device. One should hold the mask and maintain the airway while the other compresses the bag with two hands. If three rescuers are available, one rescuer can be solely responsible for maintaining the mask seal while providing spinal precautions as indicated.

When properly used, the bag-mask device has many benefits. The rescuer can provide a wide range of inspiratory pressures and volumes to adequately ventilate patients of varying sizes and underlying pathological conditions. It can be used to assist patients with shallow respirations. It performs adequately in extremes of environmental temperatures. Oxygen concentrations ranging from 21% (room air concentration) to nearly 100% (using supplemental oxygen and a reservoir) can be achieved. In addition, manual compression of the bag can give the rescuer a sense of the patient's lung compliance, which is an advantage over mechanical methods of ventilation.

TECHNIQUE

Ventilation with the bag-mask device is best accomplished when the patient has been intubated with an ET tube or a supraglottic device (e.g., the esophageal-tracheal Combitube, King LT-D airway, or laryngeal mask airway, which are described later in this chapter). If the patient has not been intubated, the bag-mask device may be used with a mask. The following technique is recommended for use with the bag-mask device.

1. The rescuer is positioned at the top of the patient's head.
2. If no spinal injury is suspected, place the patient in the optimum head-tilt chin-lift position, with the patient's head elevated in extension. (If a spinal injury is suspected, spinal precautions should be used.) If the jaw-thrust maneuver does not produce an open airway, use the head-tilt chin-lift maneuver.

3. Clear the airway of secretions, vomitus, and foreign objects. If the patient is unconscious, insert an oropharyngeal or a nasopharyngeal airway. The patient's mouth should remain open under the mask.
4. Connect an oxygen source. Then flush the reservoir with high-concentration oxygen.
5. Place the mask on the patient's face, making a tight seal. This can be accomplished by placing the thumb on the nose area and an index finger on the chin and then spreading the remaining fingers along the mandible. The anterior displacement of the mandible must be maintained. To compress the bag, the rescuer's other hand presses the bag against his or her body (e.g., the thigh), or another rescuer compresses the bag with two hands as recommended by the American Heart Association (AHA). The bag should be compressed smoothly, delivering approximately 500 to 600 mL over 1 second (for the average adult) to produce visible chest rise.

PEDIATRIC CONSIDERATIONS

Smaller bag-mask devices are needed for infants and children. This helps to reduce the chances of overinflation and barotrauma. Bag-mask devices are used mainly for pediatric patients who are in respiratory arrest. Bag-mask devices are equipped with a fish mouth– or leaf flap–operated outlet valve should not be used to provide supplemental oxygen to an infant or a child breathing spontaneously. If the valve fails to open during inspiration, the child receives only the exhaled gases from within the mask itself. For this reason, bag devices for ventilation of full-term neonates, infants, and children should have a minimum volume of 450 to 500 mL.[20] An adult (1000 mL) bag may be needed to adequately ventilate older children. At least 10 to 15 L/minute of oxygen flow is needed to maintain an adequate oxygen volume in the reservoir of a pediatric bag (Figure 15-45). Adjust the flow rate to 15 L/min when using an adult bag.

FIGURE 15-45 Pediatric bag-mask device.

NOTE
A child's flat nasal bridge makes achieving a mask seal difficult. In addition, compressing the mask against the face may result in obstruction. The mask seal is best achieved with jaw displacement using two rescuers to provide bag-mask ventilation.

Technique. The following procedure is used to artificially ventilate a pediatric patient with a bag-mask device:

1. Make sure the mask fits properly by using a length-based resuscitation tape or by measuring from the bridge of the nose to the cleft of the chin.
2. Make sure the mask is properly positioned and sealed. Place the mask over the mouth and nose (do not compress the eyes). With one hand, place a thumb on the mask at the apex and place the index finger on the mouth at the chin (like a C clamp). With gentle pressure, push down on the mask to establish an adequate seal. Maintain the airway by lifting the bony prominence on the chin, with the remaining fingers placed on the mandible, forming an E. Avoid putting pressure on the soft area under the chin.
3. Provide ventilations at a rate of 12 to 20 breaths/minute.
4. Deliver each breath over 1 second; both rescuers should make sure it produces visible chest rise.
5. Assess bag-mask ventilation by observing adequate rise and fall of the chest, by listening for lung sounds at the third intercostal space and midaxillary line, and by checking for improvement in skin color or heart rate, or both (see Chapter 19).

CRITICAL THINKING
What should you do if you find that ventilating a nonintubated patient suddenly has become more difficult?

Automatic Transport Ventilators

Several types of time-cycled, gas-powered, automatic transport ventilators (ATVs) are available. One commonly used in prehospital emergency care is the Autovent (Figure 15-46). Other, more sophisticated ATVs are used for intrahospital transport of patients who require ventilatory support (see Appendix A, Advanced Practice Procedures for the Critical Care Paramedic.) Most ATVs consist of a plastic control module. This module is connected by tubing to any 50 psi gas source (e.g., air or different concentrations of oxygen, including 100% oxygen). Depending on the model, the exit valve of the control module is connected by one or two tubes to the patient valve assembly to deliver selected tidal volumes (400 to 1200 mL for adults, 200 to 600 mL for children). Another control selects respiratory rates of 8 to 22 breaths/minute for adults and 8 to 30 breaths/minute

FIGURE 15-46 Autovent 1000, 2000, and 3000.

for children. (Most ATVs are not to be used in children under 5 years of age.) Most units provide a 40 L/minute flow of oxygen. This flow remains constant despite changes in the patient's airway or lung compliance.

NOTE
Automatic transport ventilators (ATVs) should have a default rate of 10 breaths/minute for adults and 20 breaths/minute for children. The paramedic should be able to adjust the rate once the patient has been intubated with a tracheal tube or alternative airway.[23]

The volume of gas delivered by the automatic ventilator is determined by the length of time the manual trigger is depressed or by the inspiratory effort of the spontaneously breathing patient. Most units are designed to limit the inspiratory pressure to 60 to 80 cm H_2O. When this pressure is reached, an alarm sounds and excess gas flow is vented off, preventing possible lung damage. On a nonintubated patient, ATVs allow the paramedic to use both hands to obtain a tight face-to-mask seal. On an intubated patient, ATVs allow the paramedic to perform other tasks. Most ATVs should not be used in patients who are awake, who have an obstructed airway, and/or who have increased airway resistance (e.g., pneumothorax, asthma, pulmonary edema).

NOTE
As described earlier, spontaneous breathing produces negative intrathoracic pressure during inspiration. It also plays an important role in maintaining cardiac output. It does this by enhancing venous return to the heart. Ventilations that are assisted with positive pressure ventilation using automatic transport ventilators (ATVs) or bag-mask devices produce positive intrathoracic pressure during inspiration. This reduces venous return and cardiac output. That is, cardiac output decreases as air pressure increases. The paramedic should remember that assisted ventilations can impair cardiac output, even in patients with healthy hearts. This effect is exaggerated when the patient is ventilated at an excessive rate or tidal volume. The use of an impedance threshold device to limit the influx of air in the lungs should be considered.[27]

AIRWAY MANAGEMENT

Science and technology have produced many devices for providing airway management. However, the paramedic must not neglect basic airway management procedures. *A basic procedure that secures a safe and functional airway is better than a more technically difficult procedure.* Airway management should progress rapidly from the least to the most invasive procedures and devices (Figure 15-47). Paramedics also should make sure they are always equipped with the appropriate personal protective equipment for these procedures (Box 15-9).

NOTE
Unconscious patients lack the muscular tone and control to maintain a patent airway. For this reason, an airway must be established and maintained in the initial assessment of all unconscious patients. Most injuries severe enough to cause loss of consciousness are severe enough to cause spinal injury. Spinal precautions should be considered in trauma patients who need airway management or ventilatory support until an x-ray film of the spine has been made.

Manual Techniques for Airway Management

Manual techniques for airway management have been described by the AHA. These include the head-tilt chin-lift method, the jaw-thrust method, and the jaw-thrust without head-tilt method. The paramedic should not use manual maneuvers to open the airway in patients who are responsive or when attempts to open the patient's mouth are met with resistance. All such maneuvers are hazardous if spinal injury is a factor. In addition, none of these maneuvers protects against aspiration.

The head-tilt chin-lift maneuver (Figure 15-48) is preferred for opening the airway when a spinal injury is not suspected. The head tilt is performed by placing one hand on the victim's forehead and applying firm backward pressure with the palm to tilt the head back. The fingers of the other hand then are placed under the bony part of the lower jaw (near the chin) and lifted to bring the chin forward. These fingers support the jaw and help maintain the head-tilt position.

BOX 15-9 Personal Protective Equipment

The Centers for Disease Control and Prevention (CDC) recommend that health care workers, in addition to taking the normal precautions for personal protection from communicable diseases, use masks, eyewear (e.g., safety glasses and face shields), and gowns when splashing of blood or other body fluids is likely. During airway management, certain patient reactions may occur. These may include vomiting and coughing. Exposure to blood and other body fluids also is possible. Because of these possibilities, the paramedic should observe barrier precautions.

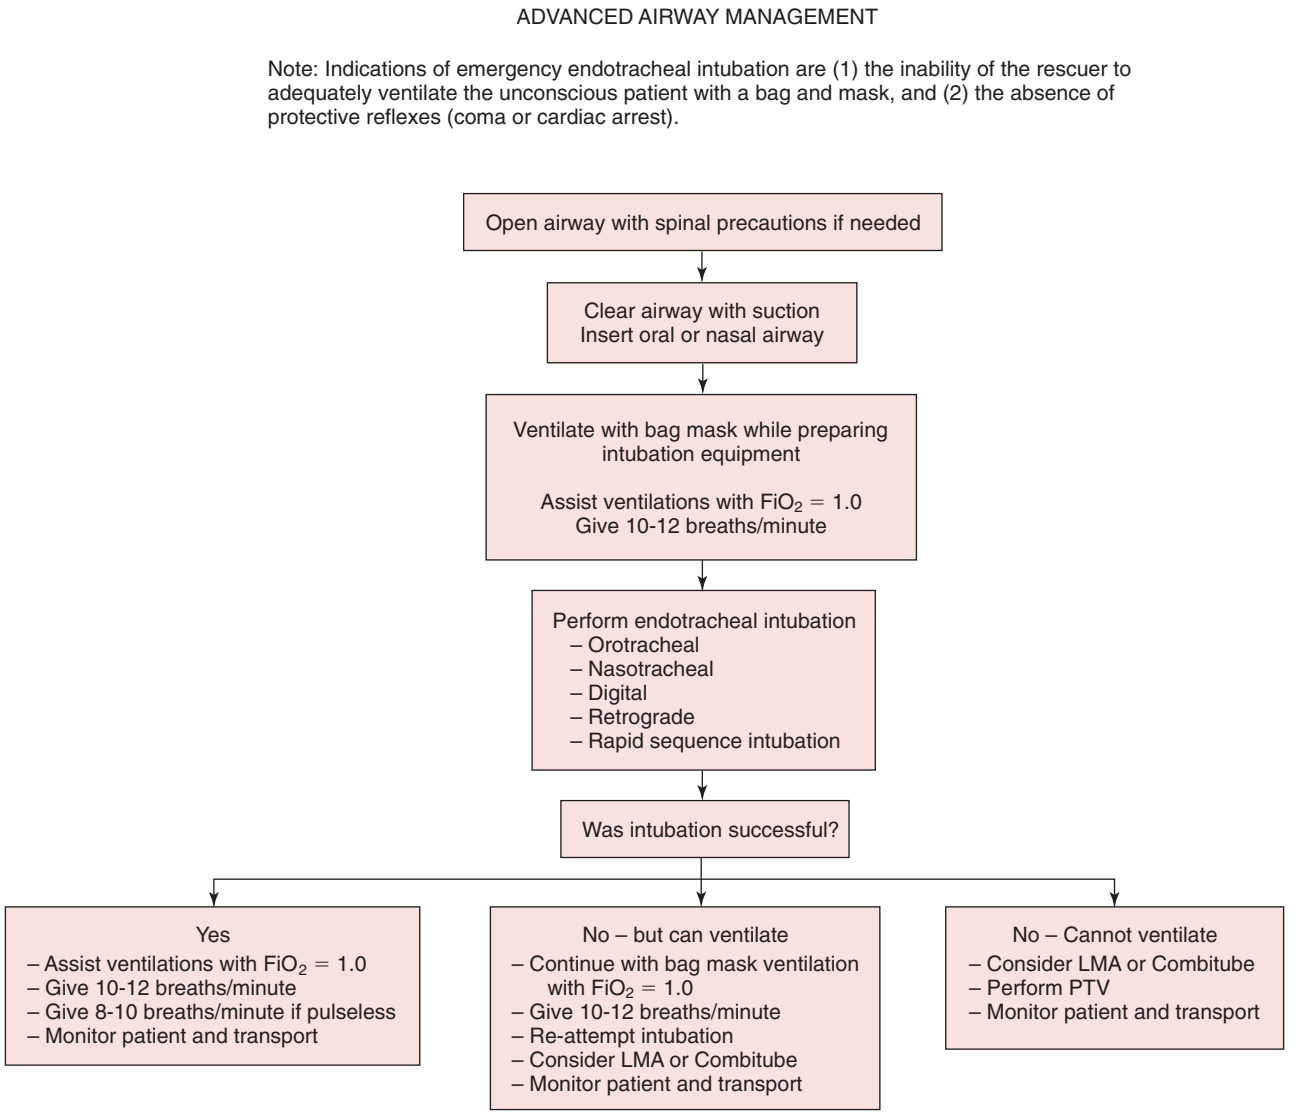

FIGURE 15-47 Advanced airway management.

The jaw-thrust maneuver (Figure 15-49) may be used to gain additional forward displacement of the mandible if no spinal injury is suspected. This is achieved by grasping the angles of the patient's lower jaw and lifting with both hands, one on each side. This displaces the mandible forward while tilting the head back. However, if the paramedic is unable to open the airway with the jaw thrust maneuver, the head-tilt chin-lift maneuver should be performed. An open airway remains the highest priority, even for an unresponsive trauma victim.

If a spinal injury is suspected, the jaw-thrust without head-tilt maneuver (Figure 15-50) should be used to open the airway. During this maneuver, the patient's head should be stabilized. Also, the cervical spine should be immobilized with neutral, in-line stabilization. The jaw-thrust maneuver should then proceed without extension of the neck.

SUCTION

Suction can be used to remove vomitus, saliva, blood, food, and other foreign objects that might block the airway or increase the likelihood of pulmonary aspiration by inhalation. Many factors can predispose a person to aspiration. For this reason, every patient should be considered a possible aspiration victim.

Suction Devices

Fixed and portable mechanical suction devices are available through a number of manufacturers. Fixed suction devices

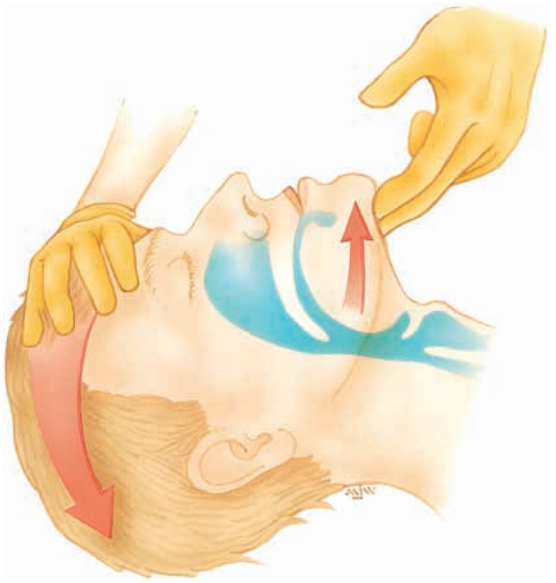

FIGURE 15-48 Head-tilt chin-lift maneuver.

FIGURE 15-49 Jaw-thrust maneuver.

FIGURE 15-50 Jaw-thrust without head-tilt maneuver.

FIGURE 15-51 Fixed suction unit.

FIGURE 15-52 Portable suction unit.

(Figure 15-51) are mounted in patient care areas of hospitals and nursing homes. They also are used in many emergency vehicles. These systems are electrically operated by vacuum pumps or powered by the vacuum produced by a vehicle engine manifold. Fixed suction devices furnish an air intake of at least 40 L/minute. They provide a vacuum of more than 300 mm Hg when the tube is clamped.

Portable suction devices may be oxygen or air powered, electrically powered, or manually powered (Figure 15-52). To operate effectively, these devices should furnish an air intake of no less than 20 L/minute.

Suction Catheters

Suction catheters are used to clear secretions and debris from the oral cavity and airway passages. The two broad classifications of catheters are whistle-tip suction catheters and tonsil-tip suction catheters.

The whistle-tip catheter is a narrow, flexible tube. It is used primarily for tracheobronchial suctioning to clear secretions through either an ET tube or the nasopharynx (Figure 15-53). This catheter is designed with molded ends and side holes to cause minimal trauma to the mucosa. It should be lubricated before insertion. A side opening in the proximal end is covered with the thumb to produce suction.

FIGURE 15-53 Soft (whistletip) suction catheter.

FIGURE 15-54 Rigid (tonsil tip, or Yankauer) suction catheter.

Using sterile technique, the paramedic advances the catheter to the desired location. Suction is applied intermittently as the catheter is withdrawn.

The tonsil-tip (Yankauer) suction catheter is a rigid pharyngeal catheter. It is used to clear secretions, blood clots, and other foreign material from the mouth and pharynx (Figure 15-54). The device is carefully inserted into the oral cavity under direct visualization. It then is slowly withdrawn while suction is activated.

Before any suctioning is begun, all equipment should be checked. Also, the suction should be set between −80 and −120 mm Hg. (Higher suction is needed for tracheobronchial suctioning.) If possible, the patient's lungs should be oxygenated with 100% oxygen for at least 2 minutes before suction is initiated. *Suction should never be applied for longer than 10 seconds in adult patients. It should never be applied for longer than 5 seconds in pediatric patients.* If more suctioning is needed, the patient's lungs should be reoxygenated first. Possible complications from suctioning include the following:

- Sudden hypoxemia that occurs secondary to decreased lung volume during the application of suction
- Severe hypoxemia that may lead to cardiac rhythm disturbances and cardiac arrest
- Airway stimulation that may increase arterial pressure and cardiac rhythm disturbances
- Coughing that may result in increased intracranial pressure with reduced blood flow to the brain and increased risk of herniation in patients with head injury
- Soft tissue damage to the respiratory tract

TRACHEOBRONCHIAL SUCTIONING

Before tracheobronchial suctioning is performed through an ET tube (Figure 15-55), the patient must be oxygenated with 100% oxygen for 5 minutes.[7] For tracheal suctioning, a Y- or T-piece or a lateral opening should lie between the suction tube and the source of the on-off suction control. Using sterile technique, the paramedic advances the catheter to the desired location (about the level of the carina.) Suction is applied intermittently by closing the side opening as the catheter is withdrawn in a rotating motion. The patient's cardiac rhythm should be monitored throughout the procedure. If dysrhythmias or bradycardia develops, suctioning should stop. The patient then should be manually ventilated and oxygenated. Before suctioning is resumed, the patient should be ventilated with 100% oxygen for about 30 seconds.

NOTE
It may be necessary to instill 3 to 5 mL of sterile saline down the endotracheal (ET) tube to loosen secretions before suctioning.

GASTRIC DISTENTION

Gastric distention results from the trapping of air in the stomach. As the stomach enlarges, it pushes against the diaphragm and interferes with lung expansion. The abdomen becomes more and more distended (especially in small children). Resistance may be felt to bag-mask ventilation.

Management. Management of gastric distention begins by slightly increasing the bag-mask ventilation inspiratory time. (Large-volume suction should be readily available.) If possible, the patient should be placed in a left lateral recumbent position. Gastric distention that cannot be managed with these techniques may require insertion of a gastric tube (Figure 15-56).

GASTRIC TUBES

Gastric distention is very common in patients who are ventilated but have not been intubated. Gastric decompression for gastric distention or vomiting control can be achieved through nasogastric (NG) or orogastric emptying or

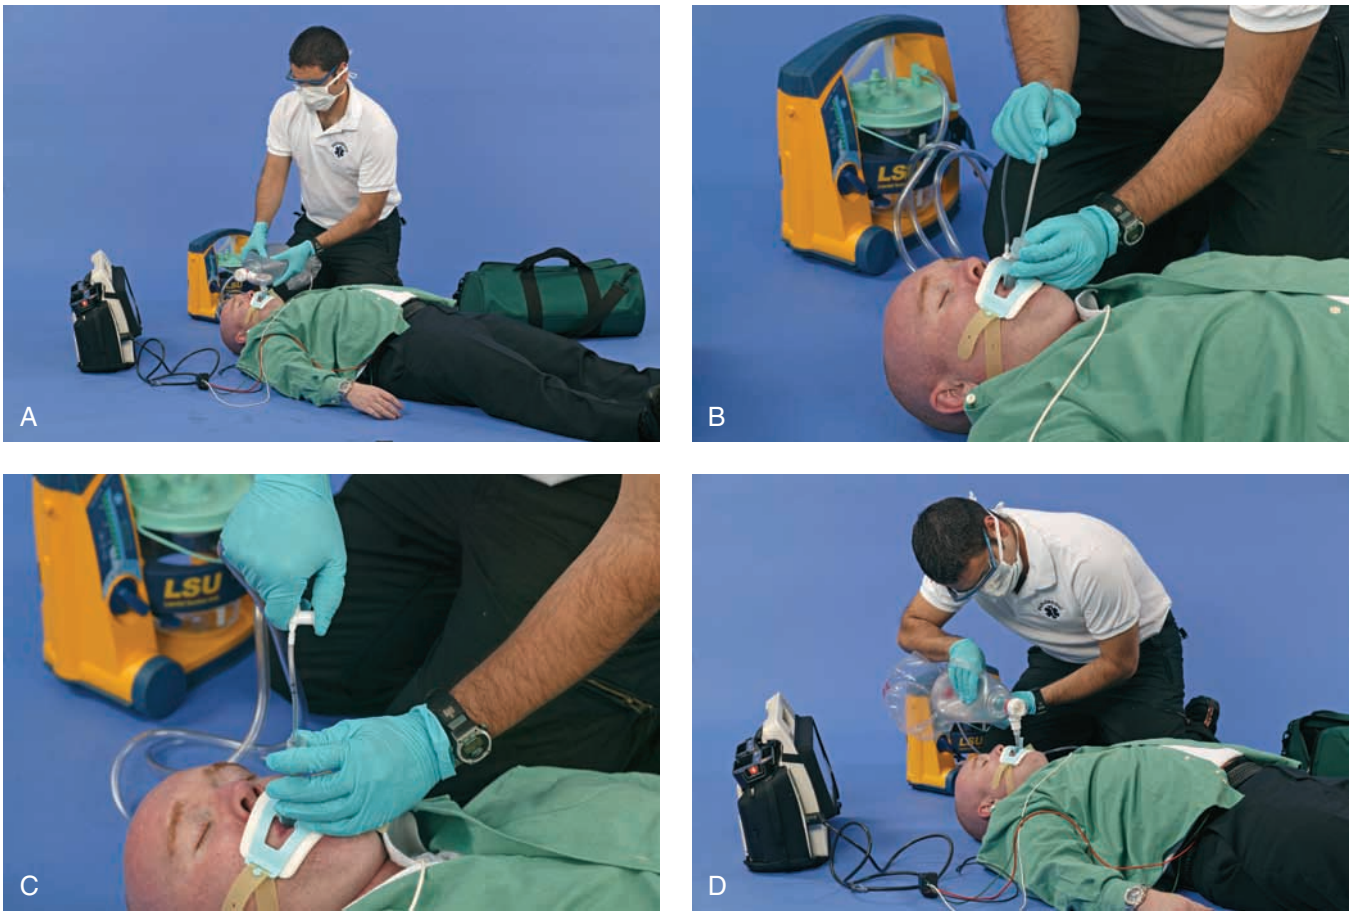

FIGURE 15-55 Tracheobronchial suctioning. **A**, Bag the intubated patient with a bag-valve device. **B**, Introduce the suction catheter through the endotracheal tube without suction. **C**, Withdraw the catheter with suction intermittently applied while observing the electrocardiographic (ECG) rhythm. **D**, Ventilate the patient and reevaluate the respiratory status.

FIGURE 15-56 *Top*, Nasogastric/orogastric tube. *Bottom*, Oral gastric lavage tube.

decompression of the stomach. Gastric decompression is done with extreme caution in patients who have esophageal trauma or esophageal disease. Gastric decompression should not be performed if an esophageal obstruction is present. NG decompression should not be attempted in a patient with facial trauma or esophageal varices (large, swollen veins in the esophagus that are susceptible to hemorrhage).

Nasogastric Decompression

1. Prepare the patient.
   (a) Place the head in a neutral position.
   (b) Preoxygenate.
   (c) Instill a topical anesthetic per protocol (check for allergies).
   (d) Locate the larger nostril.
2. Measure the NG tube from the patient's nose to the ear and from the ear to the xiphoid to determine the correct insertion length. Lubricate the tube with viscous

FIGURE 15-57 Insertion of a nasogastric tube. **A**, Position the patient. Measure the tube from the nose to the ear and from the ear to the xiphoid process. **B**, Lubricate the tube and insert it into the larger nostril. Advance the tube to the proper length. **C**, Verify correct placement of the tube by injecting 30 to 50 mL of air while auscultating over the epigastric area. **D**, Secure the tube and attach the suction unit.

lidocaine or water-soluble lubricant per protocol (Figure 15-57).

3. Advance the tube gently along the nasal floor and into the stomach. (Having the patient swallow during insertion may help advance the tube into the esophagus and prevent tracheal insertion.) If the patient is conscious and starts to cough vigorously, ask him or her to speak. If the patient is unable to do so, the tube likely has passed through the vocal cords.
4. Confirm placement per agency protocol.
   (a) Auscultate the epigastric region while injecting 30 to 50 mL of air.
   (b) Note gastric contents in the NG tube.
   (c) Make sure no reflux appears around the NG tube.
5. Secure the NG tube in place and attach to suction if indicated.

DID YOU KNOW?

Many clinical sites no longer use auscultation as a method to verify nasogastric (NG) tube placement. pH testing and radiographic verification are used instead. Aspiration of gastric contents provides a means of measuring fluid pH and of verifying placement of the tube tip in the gastrointestinal tract. The aspirate is obtained by attaching a catheter-tipped syringe to the end of the tube and pulling back gently on the syringe. (The aspirate usually is cloudy and green, off-white, tan, bloody, or brown.) The pH of the aspirate is measured with color-coded pH paper (Gastroccult), which is graded in whole numbers from 1 to 11. Gastric secretions usually are highly acidic (preferably a 4 or lower), compared with intestinal aspirates (usually greater than 4), or respiratory secretions (usually greater than 5.5).[28]

Orogastric Decompression

1. Prepare the patient and tube as described for NG insertion.
2. Introduce the orogastric tube down the midline of the oropharynx and into the stomach.
3. Confirm placement. Secure the orogastric tube as described for NG insertion.

Complications of Gastric Decompression. Whatever the method chosen, gastric decompression is uncomfortable for the patient. It may induce nausea and vomiting even when the gag reflex is suppressed. In addition, gastric tubes interfere with mask seals. They also interfere with visualization of airway structures during intubation. Complications of the procedures include nasal, esophageal, or gastric trauma; tracheal placement; and gastric tube obstruction.

MECHANICAL ADJUNCTS IN AIRWAY MANAGEMENT

The use of mechanical devices for airway management should never delay manual opening of the airway. These devices should be used only after efforts have been made to open the airway manually.

Nasopharyngeal Airway (Nasal Airway)

Nasal airways (Figure 15-58) are used to maintain an open airway passage in unconscious patients or in patients who are responsive but not alert enough to control their own airway. Insertion of a nasal airway may be useful as a temporary airway maintenance maneuver. It may be used to control the airway in patients with seizures or possible cervical spine injury. It also may be used before nasotracheal intubation (described later in this chapter). In addition, it can serve as a guide for insertion of an NG tube.

CRITICAL THINKING

Think about two or three specific patient conditions that would warrant the use of a nasal airway.

DESCRIPTION

Nasal airways are soft and pliable. They have a gentle curve, and the outer end is flared. Nasal airways are available in a variety of sizes to accommodate infants and adults. They range in length from 17 to 20 cm (about 7 to 8 inches) and in size from 12 to 36 French. (As with most other catheters, the French scale system is used to indicate internal diameter. Each unit of the scale equals about ⅓ mm. A 21 French catheter, for example, is 7 mm [about ⅓ inch] in diameter.)

To determine the correct size, the paramedic should choose an airway with a tube length equal to the distance from the tip of the patient's nose to the earlobe (Figure 15-59).

The following are recommended sizes of nasopharyngeal airways:

- Large adult: 8 to 9 mm (0.3 to 0.35 inch) internal diameter (24 to 27 French)
- Medium adult: 7 to 8 mm (about ⅓ inch) internal diameter (21 to 24 French)
- Small adult: 6 to 7 mm (about ¼ inch) internal diameter (18 to 21 French)

INSERTION

The nasal airway should be lubricated with a water-soluble lubricant. This helps ease the airway through the nasal cavity. The device is placed in the nostril with the beveled tip (designed to protect nasal structures) directed toward the nasal septum. The airway is gently passed close to the midline, along the floor of the nostril, following the natural curve of the nasal passage. The airway should not be forced. If resistance is encountered, rotating the tube slightly may help, or insertion can be attempted through the other nostril (Figure 15-60).

After insertion, the nasal airway rests in the posterior pharynx behind the tongue. If the patient begins to gag, the

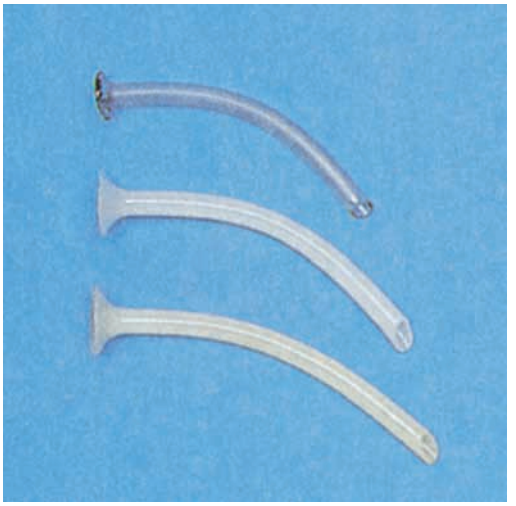

FIGURE 15-58 Nasal airways.

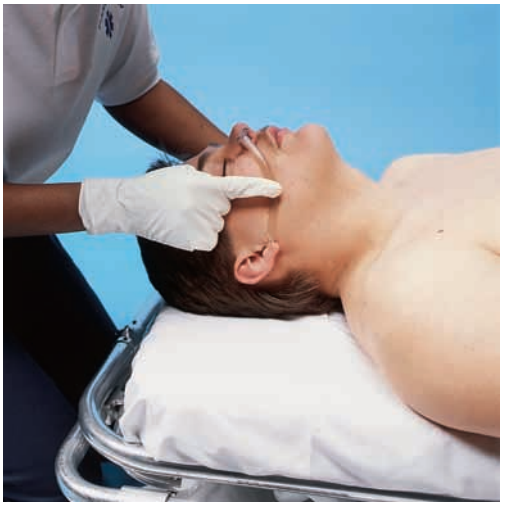

FIGURE 15-59 Measuring a nasal airway.

FIGURE 15-60 Insertion of a nasal airway.

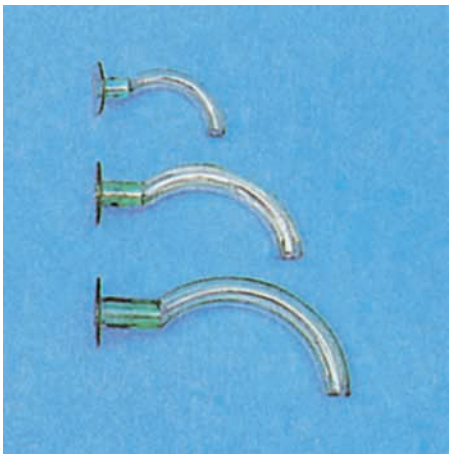

FIGURE 15-61 Oral airways.

tube may be stimulating the posterior pharynx. It may be necessary to remove the airway or withdraw it 0.5 to 1 cm (¼ to ½ inch) and reinsert it. The paramedic should maintain displacement of the mandible with either the head-tilt chin-lift or the jaw-thrust without head-tilt maneuver when using this airway.

NOTE
The cuffed oropharyngeal airway (COPA) is a modified oral airway. It has a distal inflatable cuff and proximal standard 15 mm connector. This allows attachment of a bag-mask device to the airway. The COPA may be a useful adjunct in airway management during resuscitation.

ADVANTAGES

- A nasal airway is well tolerated by conscious and semiconscious patients with an intact gag reflex.
- Insertion is a quick procedure.
- A nasal airway may be used when insertion of an oropharyngeal airway is contraindicated or difficult because of oral trauma or soft tissue injury.

POSSIBLE COMPLICATIONS

- Long nasal airways may enter the esophagus.
- The airway may precipitate laryngospasm and vomiting in patients with a gag reflex.
- The airway may injure the nasal mucosa, causing bleeding and possibly airway obstruction.
- Small-diameter airways may become obstructed by mucus, blood, vomitus, and the soft tissues of the pharynx.
- A nasal airway does not protect the lower airway from aspiration.
- Suctioning through a nasal airway is difficult.

Oropharyngeal Airway (Oral Airway)

Oral airways are designed to prevent the tongue from obstructing the glottis. They are indicated in unconscious or semiconscious patients who have no gag reflex, and in intubated patients who are trying to bite the ET tube.

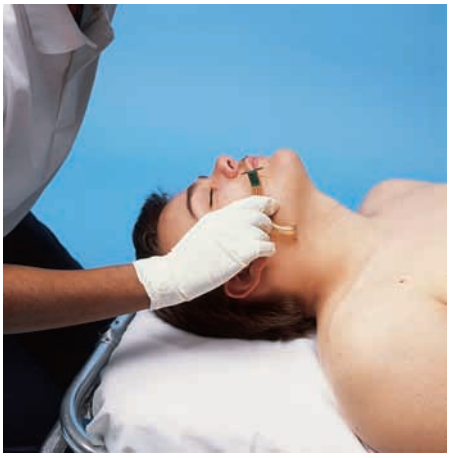

FIGURE 15-62 Measuring an oral airway.

DESCRIPTION

The oral airway is a semicircular device designed to hold the tongue away from the posterior wall of the pharynx. Most oropharyngeal airways are made of disposable plastic. The two types of airways most often used are the Guedel airway and the Berman airway. The Guedel airway is distinguished by its tubular design. The Berman airway is distinguished by the airway channels along each side of the device (Figure 15-61).

Like nasopharyngeal airways, oral airways are available in a variety of sizes ranging from infant to adult. The size is based on the distance in millimeters from the flange to the distal tip. The proper size for the patient may be determined by placing the airway next to the face so that the flange is at the level of the patient's central incisors and the bite block segment is parallel to the patient's hard palate. The airway should extend from the corner of the mouth to the tip of the earlobe or the angle of the jaw (Figure 15-62). The following sizes are recommended[20]:

- Large adult: 100 mm (about 4 inches) (Guedel size 5)
- Medium adult: 90 mm (about 3.5 inches) (Guedel size 4)
- Small adult: 80 mm (about 3.1 inches) (Guedel size 3)

INSERTION

Before an oral airway is inserted, the mouth and pharynx should be cleared of all secretions, blood, or vomitus. In an adult or older child, the oral airway may be inserted upside down or at a 90-degree angle (Figure 15-63, *A*). This helps the paramedic avoid catching the tongue during insertion. As the oral airway passes the crest of the tongue, it is rotated into the proper position. It should be situated against the posterior wall of the oropharynx. Another method of insertion is recommended for pediatric patients (Figure 15-63, *B*). (It also can be used in adults.) A tongue blade is used to displace the tongue inferiorly and anteriorly. The airway then is inserted and moved posteriorly toward the back of the oropharynx, following the normal curve of the oral cavity. Regardless of the method of insertion, care must be taken to prevent trauma to the face and oral cavity. In addition, the paramedic should make sure the patient's lips and tongue are not caught between the teeth and the airway.

FIGURE 15-63 **A,** Inserting an oral airway upside down. **B,** Recommended method of inserting an oral airway in pediatric patients.

CRITICAL THINCKING

Why is the alternative method of oral airway insertion used for infants and young children?

Proper placement of the airway is confirmed by observable chest wall expansion. It also is confirmed by good breath sounds on auscultation of the lungs during ventilation. It is important to remember that even with an oral airway in place, the patient's head must be kept in proper position. This helps ensure a patent airway.

ADVANTAGES

- An oral airway secures the tongue forward and down, away from the posterior pharynx.
- It provides easy access for airway suction.
- It serves as a bite block to protect an ET tube and the airway in the event of seizures.

POSSIBLE COMPLICATIONS

- Oral airways that are too small may fall back into the oral cavity, resulting in blockage of the airway.
- Long airways may press the epiglottis against the entrance of the trachea, producing a complete airway obstruction.
- The airway may stimulate vomiting and laryngospasm in a patient with a gag reflex.
- The airway does not protect the lower airway from aspiration.
- Improper insertion may push the tongue back, causing it to obstruct the airway.

ADVANCED AIRWAY PROCEDURES

Advanced airway procedures described in this text include subglottic and supraglottic procedures (Box 15-10). The subglottic procedures are endotracheal intubation, digital or blind intubation, and nasotracheal intubation. The supraglottic procedures include the laryngeal mask airway (LMA), the esophageal-tracheal Combitube (ETC), and the King LT-D airway. All these procedures require special training. Before performing advanced airway procedures, the paramedic must either receive authorization from medical direction or must be operating under written protocols. These written protocols are developed by medical

direction and the EMS agency. The paramedic also should be aware that long-term complications may result from these procedures. This may be true even when the procedures are performed properly. Such complications include aspiration, tracheal stenosis, transient dysphagia, and voice changes.

NOTE

Some EMS medical directors prefer the use of supraglottic procedures over subglottic procedures to initially secure a patient's airway. Paramedics should follow protocols and standing orders when providing advanced airway care.

Endotracheal Intubation

Tracheal intubation is the preferred technique for controlling the airway in patients who are unable to maintain an open airway. Indications for tracheal intubation include the following situations:

- The rescuer is unable to ventilate an unconscious patient with conventional methods (mouth-to-mask method, bag-mask device).
- The patient cannot protect his or her own airway (coma, respiratory and cardiac arrest).
- Prolonged artificial ventilation is needed.

The advantages of tracheal intubation are:

- The airway is isolated, which prevents aspiration of material into the lower airway.
- Ventilation and oxygenation are easier.
- Suctioning of the trachea and bronchi is easier.
- Wasted ventilation and gastric insufflation are prevented during positive pressure ventilation.
- A route is provided for administration of some medications (e.g., ***naloxone, atropine, vasopressin, epinephrine,*** and ***lidocaine*** [N-A-V-E-L]).

SHOW ME THE EVIDENCE

Cudnick and colleagues prospectively reviewed the records of patients transported by ground or air for two level I trauma centers in the state trauma registry (Oregon) from 2000 to 2003. Patients younger than 15 years and those whose out-of-hospital (OOH) time was longer than 100 minutes were excluded. Of the remaining 8707 patients, 570 (6.5%) underwent an intubation attempt in the field. The researchers found that the OOH time was 10.7 minutes longer for patients intubated with rapid sequence intubation (RSI) (95%; confidence interval [CI], 7.7 to 13.8) and 5.2 minutes longer for patients intubated without RSI (95%; CI, 2.2 to 8.1).

Cudnick M, Newgard C, Wang H, Bangs C, & Herrington R, IV: Endotracheal intubation increases out-of-hospital time in trauma patients, *Prehosp Emerg Care* 11:224-229, 2007.

DESCRIPTION

The common ET tube is a flexible tube open at both ends (Figure 15-64). The proximal end has a standard 15 mm (about 0.6 inch) adapter. This adapter connects to various oxygen delivery devices for positive pressure ventilation. The end of the tube that is inserted into the trachea is beveled to aid placement between the vocal cords. The adult tube size (5 or larger) has a balloon cuff that closes off the remainder of the tracheal opening. This cuff prevents aspiration of fluids around the tube. It also minimizes air leakage during ventilation. The cuff is attached to a small tube. This tube has a one-way inflating valve with a port designed to fit a standard syringe. A properly positioned ET tube with the cuff inflated allows administration of high concentrations of oxygen at controlled pressures.

FIGURE 15-64 Endotracheal (ET) tube.

- In addition to the common ET tube, specialized variations are available. An example is a tube with medication ports for ET drug administration.

ENDOTRACHEAL TUBE SIZES

The markings on the ET tube indicate the internal diameter of the tube in millimeters. (The tubes are available in graduated sizes from 2.5 to 10 mm.) The length of the tube from the distal end is indicated in centimeters at several levels. Recommended ET tube sizes are 7 to 8 mm (about ⅓ inch) internal diameter for men and 7 mm (about ¼ inch) internal diameter for women.[23] Tube sizes are expressed simply as "size 6" or "size 7," without the millimeter designation.

Infant and pediatric ET tubes are available with and without balloon cuffs. Children under 8 to 10 years of age have a circular narrowing at the level of the cricoid cartilages. This narrowing serves as a functional cuff. It minimizes air leakage at the cricoid ring. Accordingly, uncuffed ET tubes are sometimes used for this age group (see Chapter 24).

Various methods can be used to determine the correct ET tube size for infants and children. Tracheal tube size for children older than 1 year may be estimated using one of the following equations[20]:

Uncuffed tube:

$$\text{Tracheal tube size (mm)} = \frac{\text{Age (yr)}}{4} + 4$$

TABLE 15-6 Tracheal Tube and Suction Catheter Sizes*

Approximate Age/Size (Weight)	Internal Diameter of Tracheal Tube (mm)	Suction Catheter Size (F)
Premature infant (<1 kg)	2.5	5
Premature infant (1-2 kg)	3.0	5 or 6
Premature infant (2-3 kg)	3-3.5	6 or 8
Infant (6-9 kg)	3.0 cuffed	8
	3.5 uncuffed	
Toddler (10-11 kg)	3.5 cuffed	10
	4.0 uncuffed	
Small child (12-14 kg)	4.0 cuffed	10
	4.5 uncuffed	
Child (15-18 kg)	4.5 cuffed	10
	5.0 uncuffed	
Child (19-23 kg)	5.0 cuffed	10
	5.5 uncuffed	
Large child (24-29 kg)	6 cuffed	10
Adolescent/Small adult (30-36 kg)	6.5 cuffed	12
Adult female	7 cuffed	12 or 14
Adult male	7 or 8 cuffed	14

*These sizes are approximations and should be adjusted on the basis of clinical experience. Tracheal tube selection for a child should be based on the child's size or age. One size larger and one size smaller should be allowed for individual variation. Color coding based on length or on the size of the child may facilitate approximation of correct tracheal tube size.

Cuffed tube:

$$\text{Tracheal tube size (mm)} = \frac{\text{Age (yr)}}{4} + 3.5$$

A more reliable method for selecting the correct ET tube size is to use length-based resuscitation tapes (for children up to 35 kg) (see Chapter 48). Suggested sizes for ET tubes and suction catheters for adult and pediatric patients are listed in Table 15-6.[9]

NECESSARY EQUIPMENT

A laryngoscope is required for visualization of the glottis during tracheal intubation. Although various makes are available, all have a number of features in common. The standard laryngoscope includes a handle made of plastic or stainless steel. The handle contains the batteries for the light source and attaches to a plastic or stainless steel blade with a bulb placed in the distal third. The electrical contact between the blade and the handle is made at a connection point called the *fitting*. The indentation of the blade is attached to the bar of the handle. When the blade is elevated to a right angle with the laryngoscope handle, the blade snaps into place and the bulb lights (Figure 15-65). (Failure of the bulb to light may be the result of a loose connection between the bulb and the bulb socket, a damaged bulb, or faulty batteries.) Other necessary equipment includes a 10 mL syringe for cuff inflation, water-soluble lubricant, and suction equipment.

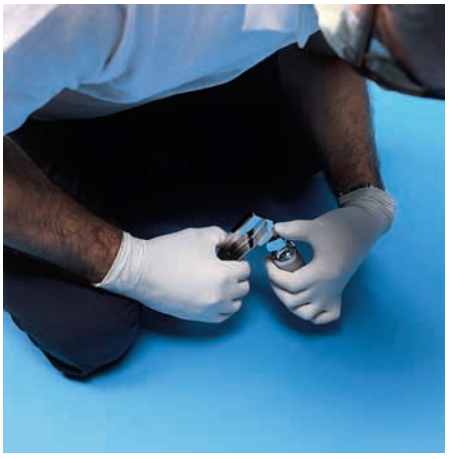

FIGURE 15-65 Attaching a blade to the handle of a laryngoscope.

Two types of blades (available in various sizes) are used with the laryngoscope: a straight blade, such as the Miller, Wisconsin, or Flagg blade (Figure 15-66), and a curved blade, such as a MacIntosh blade (Figure 15-67). The tip of a straight blade is applied directly to the epiglottis to expose the vocal cords. Advocates of the straight blade claim it provides more exposure of the glottis and less need for a stylet. A straight blade usually is recommended for infant intubation. This is because it provides greater displacement of the tongue into the floor of the mouth and better visualization of the glottic structures.

FIGURE 15-66 Types of straight laryngoscopic blades.

FIGURE 15-67 Types of curved laryngoscopic blades.

CRITICAL THINKING
Ask several paramedics and anesthesiologists which laryngoscope blade they prefer and why.

The curved blade design is intended to be inserted into the vallecula. Placement of the blade displaces the tongue to the left to elevate the epiglottis without touching it. Advocates of the curved blade claim it reduces the chance of dental trauma. They also claim it provides more room for passage of the ET tube. The choice of blade is a matter of personal preference and the patient's anatomy. Paramedics should acquire expertise in using both curved and straight blades; some patients can be intubated more easily with one type than the other. Occasions also may arise when only one type of blade is available. Versatility with both curved and straight blades may improve the patient's chances of survival.

A malleable stylet (preferably plastic coated) may be inserted through the ET tube before intubation (Figure 15-68). The stylet conforms to any desired configuration

FIGURE 15-68 ET tube with malleable stylet.

and may facilitate proper placement of the ET tube. If used, the stylet must be recessed 2.5 to 5 cm (1 to 2 inches) from the distal end of the ET tube to prevent injury to the patient. Recession of the stylet tip is maintained by bending the proximal end of the stylet over the proximal rim of the adapter so that it does not advance through the lumen with manipulation of the ET tube. If the stylet is allowed to extend beyond the distal end of the tube, the mucosal surface of the larynx or trachea or the vocal cords may be damaged. A gum elastic bougie (Figure 15-69) or tube introducer can be used to assist with ET tube placement. This large flexible device is placed in the trachea under direct visualization using a laryngoscope. The tracheal tube then is passed over the bougie and into position in the trachea.

NOTE
Lighted stylets, or "light wands," are available to assist in intubation (they are useful only in low-light environments and are intended only for adult patients). These devices have a high-intensity light at the distal end. The light is powered by a small battery housing at the operator end (Figure 15-70). This device aids placement of the endotracheal (ET) tube, because the paramedic can see the light from the end of the ET tube passing through the soft tissues of the neck.

Lighted stylets also can be used to help verify placement after intubation by other methods. Once the cuff has been inflated and lung sounds auscultated, the stylet is advanced through the ET tube. A bright light below the thyroid cartilage indicates proper placement. If the illumination creates a dim, indistinct light, the esophagus probably has been intubated.

Some EMS agencies also use Magill forceps (Figure 15-71), a scissors-style clamp with circular tips. It may be used to help direct the tip of the ET tube into the larynx during intubation and to remove some foreign bodies (Box 15-11).

FIGURE 15-69 Gum elastic bougie (tube introducer).

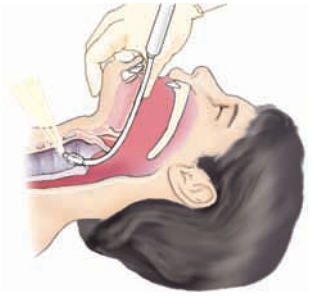

FIGURE 15-70 Fiberoptic intubation. The endotracheal tube is inserted with the aid of a lighted stylet.

FIGURE 15-71 Magill forceps.

BOX 15-11 Removal of Foreign Bodies by Direct Laryngoscopy

Direct laryngoscopy and use of Magill forceps to remove foreign bodies should be attempted only after manual techniques for clearing the airway have proved unsuccessful. The steps for removing a foreign body from the airway by direct laryngoscopy are as follows:

1. Assemble the necessary laryngoscopic equipment. (Have suction ready for immediate use in case of vomiting.)
2. Place the supine patient in the sniffing position (see Figure 15-71) with the head extended.
3. Ventilate the patient with supplemental oxygen if possible.
4. Insert the laryngoscope, visualizing the glottic opening and surrounding structures.
5. If foreign matter is seen, grasp it with Magill forceps or a Kelly clamp and remove it from the airway.
   Note: Forceps removal of foreign matter should be attempted only with direct visualization of the obstruction. Even then, caution must be exercised to avoid soft tissue damage caused by the teeth of the forceps.
6. If spontaneous respirations resume within 5 seconds, remove the blade of the laryngoscope and monitor the patient.
7. If spontaneous respirations do not resume, insert an endotracheal (ET) tube, administer 100% oxygen, and assess the patient's circulatory status.

If complete foreign body obstruction of the upper airway cannot be relieved, needle cricothyrotomy or transtracheal jet insufflation may be warranted. These advanced airway procedures provide oxygenation until tracheal intubation or tracheostomy can be performed in a controlled setting.

PREPARING FOR INTUBATION

The patient should be ventilated by other standard procedures before intubation (e.g., mouth-to-mask method, bag-mask device). The paramedic should assess the adequacy of ventilation by observing the chest rise and fall during ventilation, by auscultating for breath sounds, and by noting the patient's skin color. Before intubation, the patient should be ventilated with 100% oxygen. In a pulseless patient, the goal is to avoid interrupting chest compressions for longer than 10 seconds. Interruptions for intubations should be minimized by preparing equipment beforehand. Chest compressions should be interrupted only for the placement of the tube. Chest compressions should resume immediately after the tube is distal to the vocal cords. When more than one attempt is required, the patient should receive adequate ventilation, oxygenation, and chest compressions before each attempt. The patient's lungs should then be well ventilated and oxygenated for 15 to 30 seconds by other means before intubation is attempted again. Pulse oximetry and the electrocardiogram (ECG) should be monitored continuously during intubation attempts.

Before intubation, all equipment should be examined and tested for defects. The paramedic should check the integrity of the cuff of the ET tube by inflating the balloon with 5 to 8 mL of air and checking for leaks in the cuff or inlet port. The blade of the laryngoscope should be snapped

into place to examine the light bulb. The bulb should be secured in its socket and checked for brightness ("light, bright, and tight").

ANATOMICAL CONSIDERATIONS

The ET tube may be passed into the trachea through the mouth (orotracheal method) or through the nose (nasotracheal method). The orotracheal method is used most often. It is performed under direct visualization of the glottic opening. The nasotracheal route basically is a "blind" (nonvisualized) technique. The following anatomical structures are key landmarks during intubation:

- The trachea is in the midline of the neck with the superior entry at the level of the glottic opening. With orotracheal intubation, the vocal cords should be visualized while the tube is passed to ensure entry into the trachea.
- The uvula is suspended from the midline of the soft palate. It is used as a guide for correct placement of the laryngoscope.
- The epiglottis is attached to the base of the tongue. It should be visualized and elevated to expose the glottis and vocal cords. Pressure on the solid ring of the cricoid can block the esophagus, reducing the risk of regurgitation during the intubation attempt. It also may help the paramedic better visualize the entrance of the trachea by pushing it slightly posterior.

The trachea extends to the level of the second intercostal space anteriorly, at which point it divides into the left and right mainstem bronchi. The right main bronchus branches off at a very slight angle to the trachea, whereas the left branches at a 45- to 60-degree angle.

NOTE

An endotracheal (ET) tube that has been advanced too far most often enters the right main bronchus, bypassing and occluding the origin of the left main bronchus. If this occurs, atelectasis and pulmonary insufficiency of the left lung may result. Therefore, evaluation of ET tube placement by auscultation of both lungs is crucial. With proper ET tube placement, breath sounds should be of almost equal intensity over the two lung fields. Certain pathological conditions (e.g., pneumothorax, hemothorax, surgical removal of a lung) may result in unequal breath sounds even when an ET tube is in the proper position.

Orotracheal Intubation

In preparation for orotracheal intubation, a patient who is not a trauma victim should be placed in the sniffing position (Figure 15-72). In this position, the neck is flexed at the fifth and sixth cervical vertebrae. The head is extended at the first and second cervical vertebrae. This aligns the three axes of the mouth, pharynx, and trachea (the oropharyngolaryngeal axis), allowing direct visualization of the larynx (Figure 15-73). (When trauma is not a factor, placing a few layers of towels under the patient's head to elevate it may be helpful.)

FIGURE 15-72 Sniffing position.

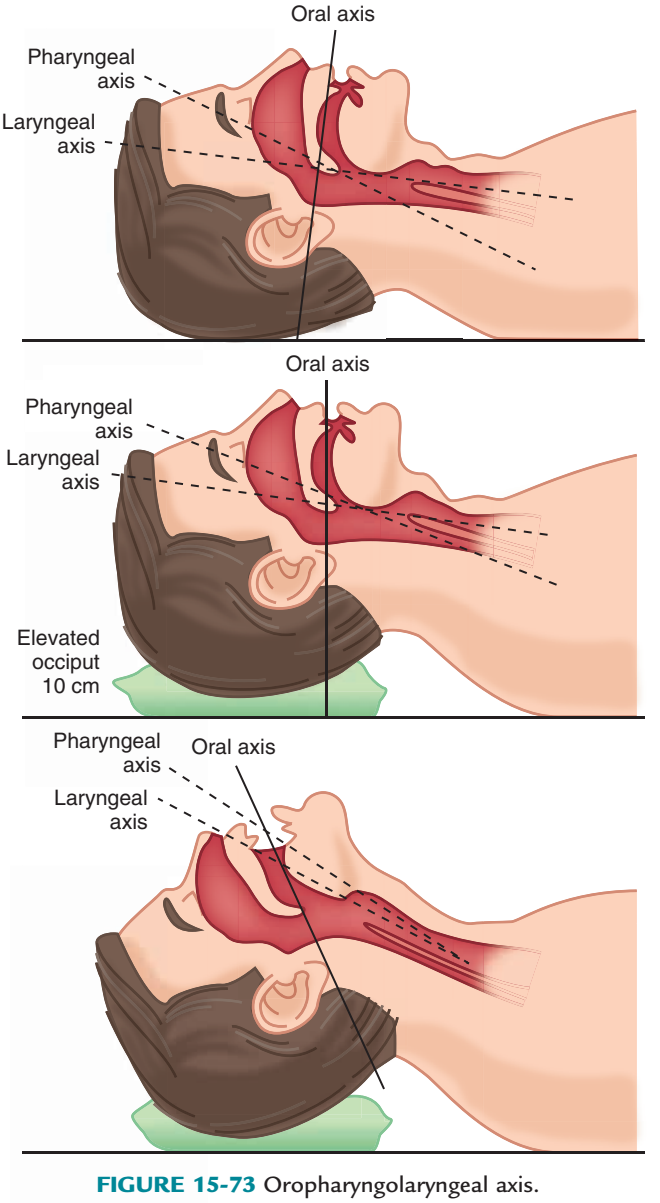

FIGURE 15-73 Oropharyngolaryngeal axis.

The orotracheal tube should be lubricated. Also, a stethoscope, stylet, and suction equipment (with large-bore catheters) should be readily available. As for all advanced airway procedures, the patient's lungs should be ventilated with 100% oxygen before intubation. The orotracheal intubation procedure is as follows (Figure 15-74):

1. Position yourself at the patient's head.
2. Inspect the oral cavity for secretions and foreign material. Suction the mouth and pharynx if needed.
3. Open the patient's mouth with the fingers of the right hand. Retract the patient's lips on the teeth or gums to avoid pinching them in the blade. The "crossed-finger technique" also may be useful in opening the patient's mouth. To perform this procedure, cross the right thumb and index finger to form an X. Place the thumb on the patient's lower incisors and the index finger on the patient's upper incisors; apply crossed-finger pressure to open the patient's mouth.
4. Grasp the lower jaw with the right hand and draw it forward and upward. Remove any dentures.
5. Holding the laryngoscope in the left hand, insert the blade into the right side of the mouth, displacing the tongue to the left. Move the blade toward the midline and the base of the tongue and identify the uvula. It is essential to work gently and avoid pressure on the lips and teeth.
6. When using a curved blade, advance the tip of the blade into the vallecula, the space between the base of the tongue and the pharyngeal surface of the epiglottis (Figure 15-75). When using a straight blade, insert the tip under the epiglottis (Figure 15-76). The glottic opening is exposed by exerting upward traction on the handle. Never use a prying motion with the handle and do not use the teeth as a fulcrum.
7. Advance the ET tube through the right corner of the mouth and, under direct vision, through the vocal

FIGURE 15-74 Orotracheal intubation. **A**, Before intubation, ventilate the patient's lungs with 100% oxygen. **B**, Hold the laryngoscope in the left hand and insert the blade into the right side of the patient's mouth, displacing the tongue to the left. **C**, Advance the endotracheal (ET) tube through the right corner of the mouth and, under direct vision, through the vocal cords. **D**, Inflate the cuff with about 10 mL of air. Ventilate the patient's lungs with a mechanical airway device. **E**, Confirm correct placement of the ET tube by primary and secondary confirmation methods. **F**, Secure the ET tube in place and provide ventilatory support with supplemental oxygen.

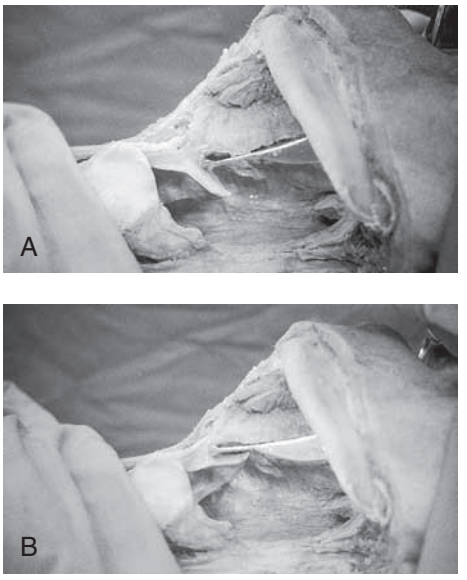

FIGURE 15-75 **A,** When a curved laryngoscopic blade is used, the tip of the blade is inserted into the vallecula. **B,** Direct pressure is exerted on the blade upward and toward the feet, and a lifting motion is used to expose the vocal cords.

FIGURE 15-76 A straight laryngoscopic blade is used to lift the epiglottis, directly exposing the vocal cords.

cords (Figure 15-77). If a stylet has been used, it should be removed from the tube after the tube passes through the cords into the trachea.

8. After viewing the vocal cords, make sure the proximal end of the cuffed tube has advanced past the cords about 1 to 2.5 cm (½ to 1 inch) (Figure 15-78). The tip of the tube should then be halfway between the vocal cords and the carina. This position allows some displacement of the tube tip during flexion or extension of the patient's neck without extubation or movement of the tip into the mainstem bronchus. (In the average adult, the distance from teeth to carina is 27 cm (about 11 inches). The paramedic should check the depth markings on the ET tube during intubation. In the average adult, the tube is properly positioned when the patient's teeth are between the 19 and 23 cm marks on the tube. This places the tip of the tube 2 to 3 cm (¾ to 1½ inches) above the carina. The average tube depth in men is 22 cm (about 9 inches) ("teeth and tube at 22"). The average tube depth in women is 21 cm (about 8½ inches).

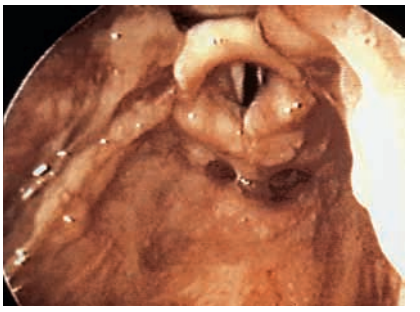

FIGURE 15-77 View of the vocal cords.

FIGURE 15-78 Endotracheal tube passing through the vocal cords.

9. Inflate the cuff with about 10 mL of air to prevent any air leaks around the tracheal cuff seal.[5]
10. Attach the tube to a mechanical airway device and ventilate the patient's lungs.
11. During ventilation, confirm accurate tube placement using primary and secondary confirmation methods.[23]

Primary Confirmation Methods. Initially confirm proper tube placement by auscultating over the epigastrium, the midaxillary region, and the anterior chest line on the right and left sides of the chest. If stomach gurgling is present or chest expansion is absent, immediately deflate the cuff and remove the tracheal tube. Reattempt intubation after oxygenating the patient's lungs with 100% oxygen for 15 to 30 seconds. When appropriate tube placement has been confirmed, reconfirm and note the tube mark at the front of the patient's teeth. Secure the tube to the patient's head and face with tape or a commercially available device. Then reevaluate lung sounds to ensure that the tube was not inadvertently repositioned. Finally, insert an oral airway or bite block. This prevents the patient from biting down and blocking the airway.

NOTE

If breath sounds are decreased or absent in the left lung, the orotracheal tube may have passed into the right mainstem bronchus, effectively bypassing the origin of the left main bronchus. If this is the case, the cuff should be deflated and the tube withdrawn 1 to 2 cm (about ½ to ¾ inch). The cuff then should be reinflated, and tube placement should be verified as explained previously.

Secondary Confirmation Methods. A second method of determining correct tube placement requires the use of mechanical devices. These include end-tidal carbon dioxide detectors, esophageal detectors, and pulse oximetry for patients who have a perfusing rhythm. These devices are described later in this chapter. Tube confirmation should include both clinical and mechanical methods. Do not rely on a single method. Confirm correct placement immediately after intubation and each time a patient is moved.

Enhanced Optical Intubation

Enhanced optical intubation devices are available and in use by some EMS systems and are appropriate for both oral and nasal intubation procedures. Visualization of the glottis is improved in these laryngoscopes by optical or video magnification. These devices include the AirTraQ, C-MAC, GlideScope, McGrath, Shikani, Storz, and others. Using an enhanced optical laryngoscope, the glottis can be visualized and intubation performed while viewing a video monitor. Like other advanced airway techniques, intubation using these devices requires special training that is manufacturer specific, as well as authorization from medical direction. Any patient who meets the criteria for intubation (described earlier) can be intubated with an optical, video or fiberoptic device[29] (Figure 15-79).

Video-assisted intubation involves inserting a video laryngoscope into the patient's mouth and then into the pharynx. Upon visual confirmation of the glottic opening, the ET tube is advanced through a specially-designed channel or alongside the laryngoscope. The tube is placed in the trachea under direct vision, using the video monitor.

Digital (Blind) Intubation

Before the advent of laryngoscopes, intubation was performed by the intubator inserting his or her fingers into the patient's mouth. The fingers were used to guide the ET tube into the trachea. This is not a common prehospital procedure. However, digital intubation may be necessary in cases of patient entrapment, in patients whose airway is blocked from view by large amounts of blood or other secretions, or if equipment fails. Digital intubation also may be used in certain disaster or tactical situations in which victims are widespread and equipment is in short supply. The procedure for digital (blind) intubation is as follows:

1. Position yourself at the patient's left side. If a spinal injury is suspected, have a second rescuer maintain in-line spinal immobilization.
2. Ventilate the patient with 100% oxygen before intubation.
3. Use a bite stick or other device to hold the patient's mouth open. This helps protect the rescuer's fingers.
4. Bend the tube and stylet combination into a J or hockey stick configuration.
5. Insert your gloved left middle and index fingers into the patient's mouth. Alternating fingers, "walk" down the patient's tongue, pulling the tongue and epiglottis away from the glottic opening.
6. When you feel a flap of cartilage covered by mucous membrane with your middle finger, you have reached the epiglottis (Figure 15-80, *A*). Maintain contact and advance the ET tube with your right hand. Use the index finger of your left hand as a guide (Figure 15-80, *B*). The index finger maintains the tube position against the middle finger, leading the tip of the tube into the glottic opening. It may be helpful for a second rescuer to perform the Sellick maneuver to close off the esophagus and help prevent aspiration.
7. Once the cuff of the ET tube passes the tips of the paramedic's fingers, inflate the cuff, remove the stylet, and verify placement in the usual manner.
8. Secure the tube as previously described.

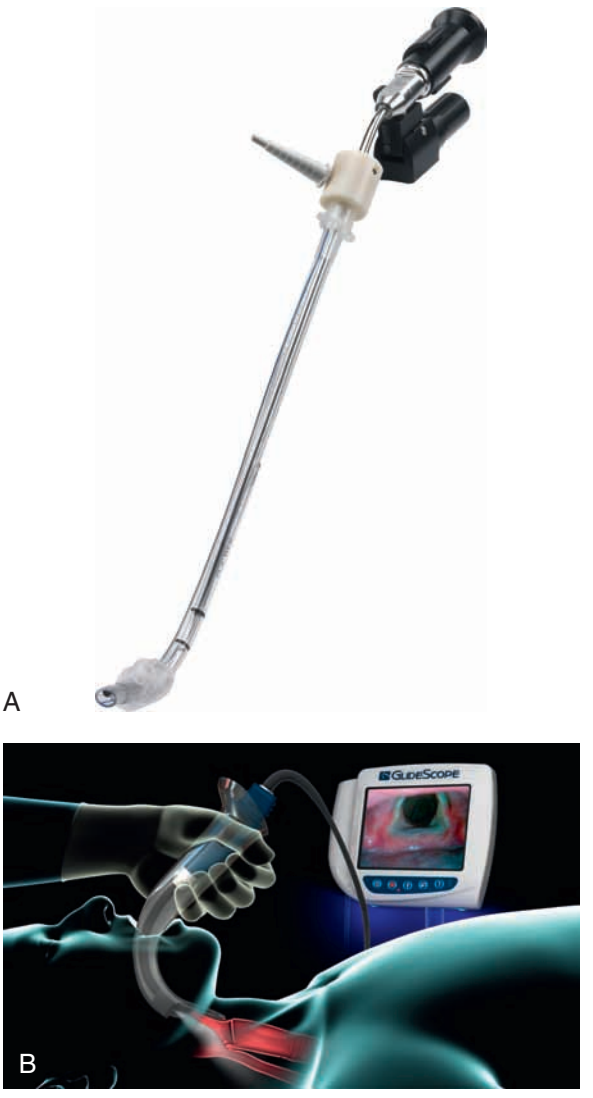

FIGURE 15-79 **A,** Shikani Seeing Optical Stylet. **B,** GlideScope. (**A** courtesy Clarus Medical, Minneapolis, Minn; **B** courtesy Verathon, Bothell, Wash.)

FIGURE 15-80 **A**, Locate the epiglottis with the tips of the fingers of one hand. **B**, Using the palpated epiglottis as a landmark, guide the endotracheal (ET) tube into the larynx.

Correct ET tube placement should be confirmed often. At a minimum, reconfirm placement each time a patient is moved or has a sudden change in condition.

Potential Complications from Intubation Procedures

- Accidental intubation of the esophagus
- Accidental intubation of a bronchus
- Lacerated lips or tongue (oral)
- Dental trauma from the laryngoscope (oral)
- Lacerated pharyngeal or tracheal mucosa
- Tracheal rupture
- Avulsion of an arytenoid cartilage
- Vocal cord injury
- Vomiting and aspiration of stomach contents
- Significant release of epinephrine and norepinephrine, leading to hypertension, tachycardia, or cardiac rhythm disturbances
- Vagal stimulation (particularly in infants and children), resulting in bradycardia and hypotension
- Increased intracranial pressure in patients with a head injury
- Hypoxia related to prolonged intubation attempts
- Displacement when the patient moves or is moved

In addition, rupture of the cuff, inflation port malfunction, or severance or kinking of the inflation tube may cause cuff malfunction and air leakage.

Nasotracheal Intubation

At times nasotracheal intubation may be the airway procedure of choice. This may be the case in patients who have spontaneous respirations, when laryngoscopy is difficult, or when the motion of the cervical spine must be limited. Examples of such conditions include the following:

- Medication overdose
- Asthma or anaphylaxis
- Chronic obstructive pulmonary disease
- Stroke
- Seizure (status epilepticus with constant seizure activity)
- Altered mental status

These and other situations may make aligning the oropharyngolaryngeal axis difficult. This rules out successful orotracheal intubation. It should be noted that nasotracheal intubation is a blind procedure. It carries a high risk of improper tube placement, because the paramedic cannot visualize the vocal cords.

In general, conscious patients tolerate a nasotracheal tube better than an orotracheal tube. Also, a nasotracheal tube often causes less trauma to the tracheal mucosa. This is because the tube moves less inside the trachea with head motion than does an orotracheal tube. If time allows, the paramedic should prepare the patient using a vasoconstrictor spray and topical anesthetic. (Examples of these are phenylephrine spray and lidocaine jelly.) These measures may make the patient more comfortable. They also reduce the risk of nasal hemorrhage, which may occur secondary to the procedure. If time allows, placement of a soft nasopharyngeal airway before the procedure may show which nostril is more passable. This also may compress the mucosa, allowing less traumatic placement of the ET tube (Figure 15-81).

NOTE
Nasotracheal intubation is not recommended in patients who are apneic, who have midfacial fractures or nasal fractures, or who are suspected of having a basilar skull fracture.

INSERTION

The procedure for inserting a nasotracheal tube is as follows:

1. Choose a cuffed ET tube that is 1 mm smaller than optimal for oral intubation. (Most ET tubes are designed for both orotracheal and nasotracheal intubation. Some longer ET tubes are designed specifically for this procedure. A ringed ET tube [Endotrol] also is available that controls the tip of the ET tube, aiding entry into the trachea.) Prepare and check all needed equipment (balloon cuff, syringe, suction, stethoscope). Stylets are not used in nasotracheal intubation. This is because the stylet reduces flexibility and increases the risk of injury during blind insertion.
2. Ventilate the patient with 100% oxygen before intubation.

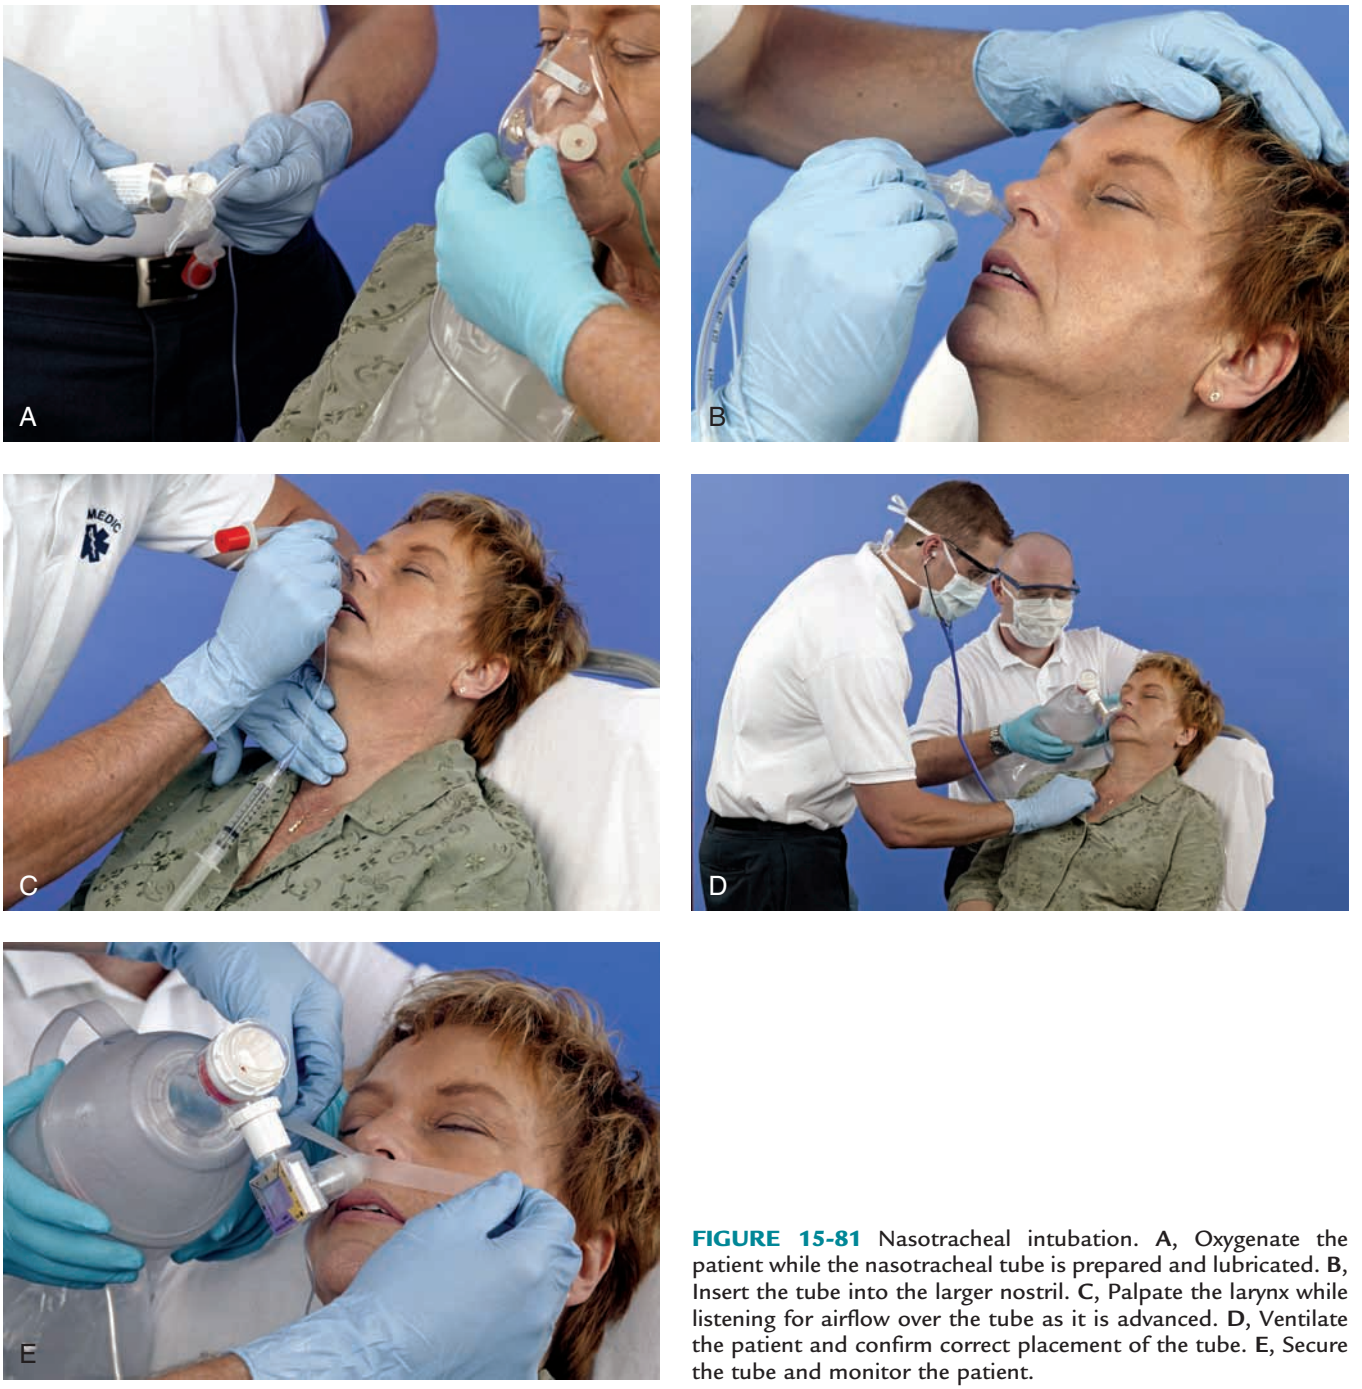

FIGURE 15-81 Nasotracheal intubation. **A**, Oxygenate the patient while the nasotracheal tube is prepared and lubricated. **B**, Insert the tube into the larger nostril. **C**, Palpate the larynx while listening for airflow over the tube as it is advanced. **D**, Ventilate the patient and confirm correct placement of the tube. **E**, Secure the tube and monitor the patient.

3. Lubricate the ET tube with a water-soluble or lidocaine jelly.
4. Insert the tube with the flange facing the nasal septum. Advance the tube along the nasal floor of the nostril that is clearer and more direct. If both nostrils appear open, advance through the larger nostril first. If the chosen nostril is impassable, try the other nostril before selecting an ET tube that is 0.5 mm smaller in diameter.
5. Stand beside the patient with one hand on the tube and the thumb and index finger of the other hand palpating the larynx. The curve of the tube should follow the natural curve of the airway. Gently advance the tube while rotating it medially 15 to 30 degrees until maximal airflow is heard through the tube. (Airflow sounds can be amplified by placing a simple device called the Beck airway airflow monitor [BAAM] whistle on the end of the endotracheal tube.) Gently

and swiftly advance the tube during early inspiration. Voluntary tongue extrusion in cooperative patients is helpful. Otherwise, the tongue can be wrapped with gauze and pulled forward. Flexion of the neck (if no spinal instability is suspected) and posterior pressure on the thyroid cartilage may help position the larynx.

6. Externally observe the advancement of the tube toward the carina. Misting or condensation on the tube should be evident as the tube approaches tracheal placement. This occurs because the patient's exhaled breath has a high concentration of water vapor. The water vapor promptly condenses on exposure to cooler room air. However, tube misting is not always a reliable indicator of proper tube position.
7. On completion of intubation, verify proper tube placement as described before. Inflate the cuff with about 10 mL of air and secure the tube in place. Ventilations may then be assisted with supplemental oxygen, or the patient's lungs can be ventilated by mechanical means.
8. If intubation fails, withdraw the tube and redirect it after ventilating and oxygenating the patient. It may be possible to recognize tube misplacement by inspecting and palpating the neck for bulges.

NOTE

Another device used to aid placement of the nasotracheal tube is the airway whistle, or Beck Airway Airflow Monitor (BAAM). The whistle, which is attached to the standard 15 mm endotracheal connector, amplifies the patient's breathing as the tube is advanced through the posterior nasopharynx. As the tube is advanced farther, the sound increases in intensity. Deviation from the airflow tract results in a decrease in or loss of the whistle sound, indicating a need for tube redirection. Once intubation is complete, the airway whistle is removed.

POSSIBLE COMPLICATIONS

- Epistaxis (nosebleed)
- Vagal stimulation
- Injury to the nasal septum or turbinates
- Retropharyngeal laceration
- Vocal cord injury
- Avulsion of an arytenoid cartilage
- Esophageal intubation
- Intracranial tube placement if the patient has a basilar skull fracture

Intubation with Spinal Precautions

Nasal or oral intubation may be performed in patients suspected of having a spinal injury. The procedure is as follows:

1. Auscultate for bilateral breath sounds while manual or mechanical ventilations are in progress. This provides a baseline.
2. One rescuer should apply manual in-line stabilization from the patient's side. The rescuer places the hands over the patient's ears. The little fingers should be under the occipital skull. The thumbs should be on the face over the maxillary sinuses. Stabilization (without distraction) should be maintained in a neutral position throughout the procedure. Thin padding under the patient's head may be necessary to maintain neutral, in-line positioning.

NOTE

Intubation of patients suspected of having a spinal injury is controversial[30] and should be authorized by medical direction. Any type of airway manipulation may be dangerous. If the paramedic and medical direction elect to intubate the trachea of a patient suspected of having a spinal injury, in-line stabilization must be maintained. Two trained rescuers are required. Video-assisted devices may be helpful in these situations.

3. In one method of intubation, the primary paramedic is positioned at the patient's head. The legs straddle the patient's shoulders and arms, and the patient's head is secured between the paramedic's thighs. The grip of the primary rescuer in this position and of the other rescuer (from the side) prevents the head from moving during the intubation. In this position, the primary paramedic may need to lean back to visualize the vocal cords (Figure 15-82). With another method, the primary paramedic lies prone at the patient's head, and the other rescuer (at the patient's side) maintains the in-line position alone (Figure 15-83).

FACE-TO-FACE OROTRACHEAL INTUBATION

Face-to-face orotracheal intubation (Figure 15-84) may be used when the paramedic cannot take a position above the patient's head (e.g., the patient is in a sitting position). In

FIGURE 15-82 Intubation in a sitting position.

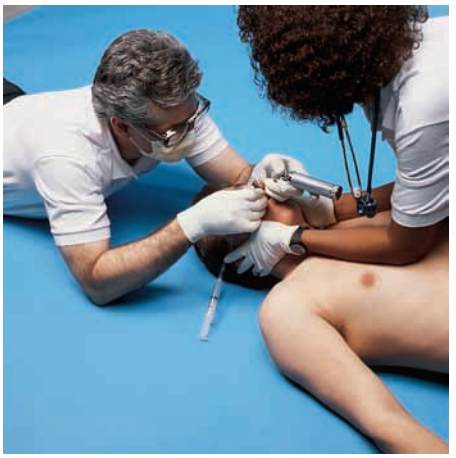

FIGURE 15-83 Intubation in a prone position.

this method of intubation, a second rescuer maintains in-line immobilization of the patient's neck and head from behind the patient. The primary rescuer takes a position facing the patient. The patient's mouth is opened with the left hand. The laryngoscope is held in the right hand, and the blade is inserted into the patient's mouth, following the normal curve of the tongue. After visualizing the vocal cords from a position above the patient's mouth, the primary rescuer passes an ET tube between the cords with the left hand. The cuff is inflated and the syringe removed. The patient then is ventilated with a bag-mask device. After proper placement has been confirmed as previously described, the ET tube is secured in place. Video laryngoscopy devices can be helpful when spinal motion needs to be restricted and in face-to-face situations.

FIGURE 15-84 Face-to-face orotracheal intubation. **A**, One rescuer maintains in-line immobilization. The primary rescuer takes a position facing the patient and opens the person's mouth. The primary rescuer then should follow these steps: **B**, Hold the laryngoscope in the right hand and insert it into the patient's mouth. **C**, With the left hand, pass the endotracheal (ET) tube into the mouth and through the vocal cords. **D**, Inflate the cuff. Ventilate the patient and confirm correct placement of the tube. Secure the tube in place.

EXTUBATION

The ET tube is not usually removed in the prehospital setting. However, the patient may develop intolerance to the tube. Also, sedating the patient to improve tolerance may not be possible. In such cases medical direction may advise extubation. If time allows, the patient's lungs first should be ventilated with 100% oxygen. To remove the ET tube, the paramedic should tilt the patient or backboard to one side and proceed as follows:

1. Have suction available. (The oral cavity and the area above the cuff should be suctioned before the ET tube is removed.)
2. Deflate the cuff completely.
3. Swiftly withdraw the tube on cough or expiration.
4. Assess the patient's respiratory status.
5. Provide high-concentration oxygen; assist ventilations as needed.

NOTE
Patients who are awake are at high risk of laryngospasm immediately after extubation. Also, they may be difficult to reintubate should respiratory distress or failure recur.

Advantages of Endotracheal Intubation

- It provides complete airway control.
- It helps prevent aspiration.
- It prevents gastric distention.
- It may provide a route for administration of some drugs.
- Positive pressure ventilation can be delivered.
- It allows tracheal suctioning.
- High concentrations of oxygen and large volumes of ventilation can be delivered.

Special Considerations for Pediatric Intubations

In addition to the differences in airway and ventilation procedures for pediatric patients, the anatomical differences of the pediatric airway must be considered.[23] These anatomical differences include the following:

1. The infant's upper airway is relatively small; the tongue is disproportionately large. Therefore posterior displacement of the tongue easily obstructs the airway. In addition, the larger tongue of the pediatric patient tends to make laryngoscopy more difficult. Have another rescuer pull on a corner of the mouth to increase visualization.
2. The epiglottis is shaped like the Greek letter omega (Ω). It is narrower and longer in children than in adults. Because of this, the epiglottis is more difficult to control with a laryngoscopic blade. The larynx lies more anteriorly in relation to the base of the tongue than in the adult. It also is elevated under the base of the tongue, making visualization more difficult. The glottic opening is at the third cervical vertebra in premature neonates, the third to fourth cervical vertebrae in term neonates, and the fourth to fifth cervical vertebrae in adults.
3. During the first few months of life, the infant's vocal cords slope from back to front. As a result, the ET tube frequently gets hung up in the angle formed by the cords. This problem can be minimized by rotating the ET tube or by having a second rescuer perform the Sellick maneuver during intubation.
4. The cricoid cartilage is the narrowest part of the airway in the infant and young child. As the child reaches 8 to 10 years of age, the vocal cords become the narrowest part. This remains the case into adulthood.
5. The distance from the vocal cords to the carina varies and can be correlated with the patient's height. This distance is about 4 to 5 cm (2 to 2½ inches) at birth and 6 to 7 cm (3 to 3½ inches) by 6 years of age. During placement of the ET tube, the tube should be advanced until breath sounds are lost unilaterally (usually on the left side). It should then be withdrawn slowly until breath sounds return, indicating that the tube tip is at the carina. After the return of breath sounds, the tube should be withdrawn 2 to 3 cm (¾ to 1½ inches) farther, placing it at a safe distance above the carina and below the cords. The tube then should be secured with tape or a commercial device.

NOTE
The correct depth of insertion for an endotracheal (ET) tube in children over age 2 can be approximated by adding one half the patient's age to 12.

$$\text{Depth of insertion (cm)} = \frac{\text{Patient's age}}{2} + 12$$

Alternatively, the depth of insertion can be estimated by multiplying the internal diameter of the tube by 3.[20]

$$\text{Depth of insertion (cm)} = \text{ET tube internal diameter} \times 3$$

6. Children use the diaphragm as the major muscle for ventilation. They require full diaphragmatic excursion to breathe. Gastric distention caused by swallowing air or artificial ventilation can inhibit the child's respiratory efforts. Infants are nose breathers until 3 to 5 months of age.
7. Deciduous teeth begin to develop at about 6 months. These are lost between 6 and 8 years. They may become dislodged during airway procedures such as intubation and oral airway insertion and by the child biting on the airway.

During any airway procedure, the paramedic should remember that the airway structures of children are very fragile and easily damaged. Therefore, great care must be taken not to injure these patients.

Adjuncts to Aid Confirmation of Endotracheal Tube Placement

Several adjuncts often can help the paramedic determine correct ET tube placement. These include end-tidal carbon dioxide detectors, bulb- or syringe-type esophageal detection devices, and pulse oximeters. As stated previously, confirmation of tube placement requires more than one method of assessment.

END-TIDAL CARBON DIOXIDE DETECTORS

Capnography is the measurement of carbon dioxide concentrations in exhaled air. This measurement is made possible by end-tidal carbon dioxide ($EtCO_2$) detectors. $EtCO_2$ detectors are designed to help verify placement of the ET tube. They also are designed to reveal inadvertent esophageal intubation. These devices provide a noninvasive estimate of alveolar ventilation, carbon dioxide production, and arterial carbon dioxide content. Their use as an adjunct to assessment of ET tube placement is strongly encouraged.[20,23]

NOTE
The color indicators of colorimetric carbon dioxide (CO_2) detectors can be affected by vomitus. They also can be affected if the patient recently drank a carbonated beverage (if the endotracheal tube is placed in the esophagus).

Three types of carbon dioxide detectors are available: disposable colorimetric devices and electronic capnometry and capnography devices. Colorimetric devices contain a chemical indicator that is sensitive to carbon dioxide. When the detector is attached to the ET tube, the color of the indicator changes with elevated carbon dioxide. These elevations would be expected in the trachea but not in the esophagus. A memory aid for colorimetric devices is as follows: *yellow* (yes, the ET tube is correctly placed in the trachea); *tan* (think about it; the ET tube may not be in the trachea); and *purple* (problem; the ET tube is not in the trachea). Colorimetric devices provide limited information and can be used only for short periods. Exposure to secretions may render them ineffective (Figure 15-85).

NOTE
Cardiac output is very low during cardiopulmonary resuscitation. Consequently, colorimetric devices may show no color change even when the endotracheal (ET) tube is in the trachea. In such cases, a second method of confirming tube placement should be used, such as an esophageal detector device.

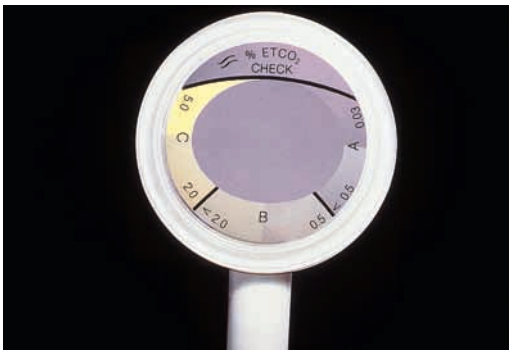

FIGURE 15-85 Colorimetric end-tidal carbon dioxide (CO_2) detector.

A capnometer is an electronic device for measuring the $EtCO_2$. The monitor probe or sampling tubing is connected between the ET tube and the bag-valve device. Because capnometers display a numerical end-tidal CO_2 value, changes can be measured over time.

Capnography is a method of measuring carbon dioxide that displays and records both a numerical value for the $EtCO_2$ and a dynamic wave form. This provides a visual display of the rate, depth, and effectiveness of the patient's ventilation. It does not measure oxygenation. Because carbon dioxide is a waste product of metabolism, capnography also provides an indirect measure of perfusion. This is important during cardiopulmonary resuscitation. A decline in $EtCO_2$ values may indicate that chest compressions are not fast enough or deep enough. Capnographic wave forms also can provide information about bronchoconstriction. When the terminal bronchioles are constricted, the upslope of the capnographic waveform resembles a shark's fin. This is related to uneven emptying of air from the narrowed airways. Paramedics can monitor the capnographic waveform to evaluate the effectiveness of bronchodilator treatment (see Chapter 24).

SHOW ME THE EVIDENCE
Wirtz and colleagues sought prospectively to find the incidence of unrecognized prehospital endotracheal tube misplacement in patients arriving at two emergency departments (ED) in New York City from 17 EMS agencies from February, 2003 to June, 2004. Only one agency used end-tidal carbon dioxide (CO_2) detectors. Paramedics intubated 132 patients during the study period. Eleven endotracheal tubes were placed in the esophagus, and one was placed in the hypopharynx. In addition, 15% of patients had right mainstem intubation on arrival at the ED. Eleven of the 12 patients with unrecognized esophageal intubation died.

Wirtz D, Ortiz C, Newman D, Zhitomirsky I: Unrecognized placement of endotracheal tubes by ground prehospital providers, *Prehosp Emerg Care* 11:213-218, 2007.

NOTE

Capnography provides a breath-by-breath measurement of a patient's ventilation. It therefore can quickly reveal a trend in a patient's condition and provide early warning of a decline in a patient's respiratory status. Capnography is useful for monitoring patients with asthma, congestive heart failure, diabetes, shock, pulmonary embolus, acidosis, and other conditions. A high end-tidal carbon dioxide ($EtCO_2$) reading in a patient with altered mental status or severe dyspnea may indicate hypoventilation and the need for tracheal intubation.

SHOW ME THE EVIDENCE

Silvestri and coworkers performed a prospective observational study for 10 months in 2002 on all adult and pediatric patients who had out-of-hospital endotracheal intubation and were taken to a level I trauma center. Use of continuous end-tidal carbon dioxide ($EtCO_2$) monitoring was available but not required by all of the participating EMS services. During this period, 153 patients who arrived at the trauma center had been intubated and met the study criteria. Continuous $EtCO_2$ monitoring was used for 93 (61%) patients; none of these patients had unrecognized misplaced intubation. In the group in which continuous $EtCO_2$ monitoring was not used, 13 patients had esophageal intubation and one patient had hypopharyngeal placement. This constituted a 23% misplacement rate.

Silvestri S, Ralls G, Krauss B, et al: The effectiveness of out-of-hospital use of continuous end-tidal carbon dioxide monitoring on the rate of unrecognized misplaced intubation within a regional emergency medical services system, *Ann Emerg Med* 45:497-502, 2005.

Electronic devices can confirm successful tracheal tube placement within seconds of an intubation attempt. They also can detect subsequent tracheal dislodgement.[23] An infrared analyzer measures the percentage of carbon dioxide gas at each phase of respiration (Figure 15-86). Capnometers provide a numerical reading of exhaled CO_2 levels. The information also may be displayed in a digital waveform using a capnograph with printout capability (similar to an ECG tracing) (Figure 15-87 and Box 15-12). Both colorimetric and electronic devices may be useful as indicators of circulation during some cardiac arrest situations, because an increase in the $EtCO_2$ concentration seems to be related to effective perfusion during external chest compression.[31] Some capnometers can be used in patients who have not been intubated (i.e., using a device that resembles a nasal cannula). They are helpful in determining the effectiveness of EMS treatments.

NOTE

Capnography also can be used as an early indication of return of spontaneous circulation (ROSC). Studies have shown that when a patient experiences ROSC, the first indication often is a sudden rise in the end-tidal carbon dioxide ($EtCO_2$) level. This rise occurs as the rush of circulation washes untransported CO_2 from the tissues. Likewise, a sudden drop in the $EtCO_2$ may indicate the patient has lost pulses and cardiopulmonary resusciation (CPR) may need to be initiated.[32]

FIGURE 15-86 Digital (or electronic) end-tidal carbon dioxide (CO_2) detector.

FIGURE 15-87 Monitor displaying continuous capnographic waveform.

CRITICAL THINKING

Your patient is in full arrest. Consequently, the measurements from your end-tidal carbon dioxide ($EtCO_2$) detector are inconclusive. Also, you can't get the oxygen saturation monitor to work. You are not sure whether you hear breath sounds clearly. What should you do?

BULB- AND SYRINGE-TYPE ESOPHAGEAL DETECTORS

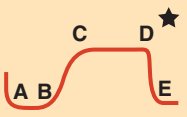
Esophageal detection devices (e.g., the Toomey syringe) are attached to the end of the ET tube (Figure 15-88). They operate on the principle that the esophagus is a collapsible tube. As such, a vacuum is created when air is removed from the esophagus. This occurs with the bulb device after it is compressed or when air is withdrawn by the syringe device if the ET tube is in the esophagus. If the ET tube has been correctly placed in the trachea, the bulb device easily refills with air or the syringe device is easily aspirated when the plunger is pulled back. Esophageal detection devices also can be used to verify correct placement of multilumen

BOX 15-12 Capnographic Waveforms

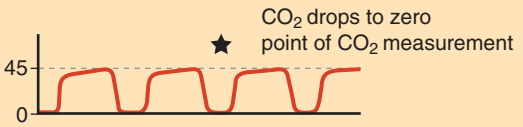
Capnography waveforms on the monitor screen are condensed to provide assessment information in a 4-second view. Printouts of waveforms provide the same information in "real time" and may differ in duration from that of the monitor screen. The following are example waveforms for both intubated and nonintubated patients.*

Normal Ranges

Arterial partial pressure of carbon dioxide ($PaCO_2$): 35-45 mm Hg
Capnography end-tidal carbon dioxide ($EtCO_2$): 35-45 mm Hg (4-6 vol%)



A–B Respiratory baseline
B–C Expiratory upslope
Exhaled CO_2 mixes with airway dead space gases
C–D Expiratory plateau
D End-tidal value—peak CO_2 concentration—normally at the end of exhalation
D–E Inspiratory downstroke



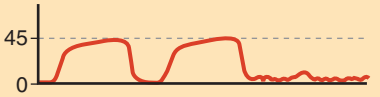
Normal capnography tracing

Intubated Patients

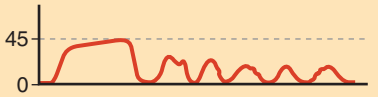
In an intubated patient, capnography may be used to:

- Verify endotracheal (ET) tube placement
- Monitor or detect ET tube dislodgement
- Monitor loss of circulatory function
- Assess the adequacy of cardiopulmonary resuscitation (CPR) compressions
- Confirm return of spontaneous circulation

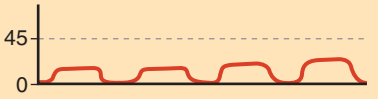
Examples



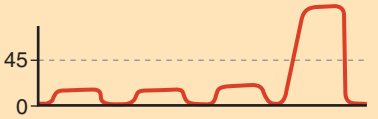
Tube dislodged, disconnected, or kinked



ET cuff problem or partial tube obstruction



CPR–goal to maintain 10 mm Hg



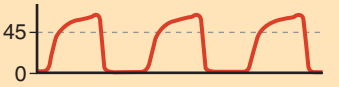
Return of spontaneous circulation

Nonintubated Patients

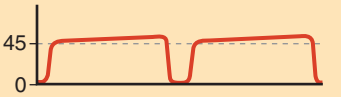
In a nonintubated patient, capnography may be used to:

- Assess asthma and chronic obstructive pulmonary disease (COPD)
- Document and monitor procedural sedation
- Detect apnea or inadequate breathing
- Measure hypoventilation
- Evaluate hyperventilation

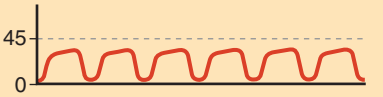
Examples



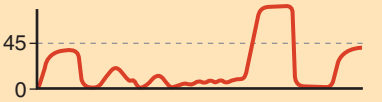
Waveform has a "shark fin" appearance during bronchospasm



Hypoventilation



Hyperventilation



Irregular apneustic breathing

Causes of Elevated $EtCO_2$

- Decreased ventilation secondary to:
  - Head trauma
  - Overdose
  - Respiratory failure (severe asthma, COPD)
  - Sedation
  - Stroke
- Increased CO_2 production
  - Fever
  - Shivering

Causes of Low $EtCO_2$

- Ventilation problem
  - Esophageal intubation
  - Airway obstruction
- Inadequate blood flow
  - Cardiac arrest (lower if poor compressions; lower values predict poor outcome)
  - Tension pneumothorax
  - Pericardial tamponade
  - Reduced cardiac output
- Ventilation/perfusion (V/Q) mismatch
  - Pulmonary embolism
- Decreased production of carbon dioxide
  - Hypothermia
- Sampling error
  - Inadequate tidal volume delivery
  - CO_2 sampling tubing blocked

Modified from Ornato JP, Peberdy MA: Prehospital end-tidal carbon dioxide monitoring—it's not all hot air, *JEMS*, March, 1993.
*The level of sedation and severity of conditions may affect the respiratory rate and $EtCO_2$ level.

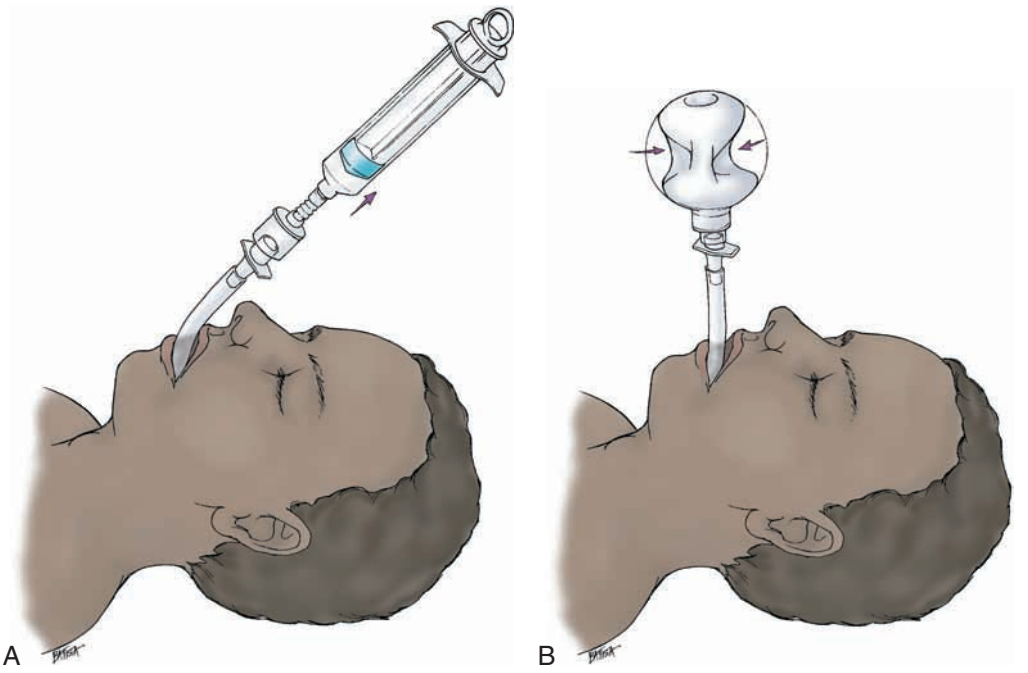


FIGURE 15-88 Esophageal intubation detector. **A,** Syringe. **B,** Bulb.

airways (described later in this chapter), provided the device is applied before the first breath is delivered after intubation.

PULSE OXIMETRY

Pulse oximeters (Figure 15-89) help determine how well the patient is being oxygenated. They measure the transmission of red and near-infrared light through arterial beds. Hemoglobin absorbs red and infrared light waves differently when it is bound with oxygen (oxyhemoglobin) from when it is not (reduced hemoglobin). Oxyhemoglobin absorbs more infrared than red light. Reduced hemoglobin absorbs more red than infrared light. Pulse oximetry reveals the arterial saturation (SpO_2) by measuring this difference.

The oximeter probe is placed on an area of thin tissue, such as a finger, toe, or earlobe. One side of the probe sends wavelengths of light through the arterial bed. The other side detects the presence of red or infrared light. Using this balance of red and infrared colors, the oximeter calculates the oxygen saturation of the blood and displays it on the monitor screen.

FIGURE 15-89 Pulse oximeter. (Shade BR et al: *Mosby's EMT-Intermediate textbook for the 1999 National Standard Curriculum,* ed 3, St Louis, 2007, Mosby.)

NOTE

Comprehensive assessment of a patent's ventilation and perfusion status requires blood gas analysis (an in-hospital procedure). As described in Chapter 11, blood gas analysis is used to assess pH, the partial pressure of arterial carbon dioxide ($PaCO_2$), bicarbonate, and base deficit. (Methods used to obtain arterial blood gas samples are presented in the Appendix: Advanced Practice for the Critical Care Paramedic.

The percentage of hemoglobin saturated with oxygen is denoted as the SaO_2. It depends on a number of factors. These include the PCO_2, pH, temperature, and whether the hemoglobin is normal or altered. The lower range of normal for the SpO_2 is 93% to 95%. The upper range is 99% to 100%. Once the SpO_2 falls below 90% (corresponding to a PO_2 of 60 mm Hg), further decreases are associated with a marked decline in oxygen content (Box 15-13).

Difficulties and inaccuracies may result from the use of pulse oximeters. Therefore, paramedics should consider them only as another tool to assist the monitoring of a patient's oxygenation levels. Circumstances that may produce false readings include the following[33]:

- Dyshemoglobinemia (hemoglobin saturation with compounds other than oxygen (e.g., carbon monoxide, methemoglobinemia)
- Excessive ambient light (sunlight, fluorescent lights) on the oximeter's sensor probe
- Patient movement
- Hypotension
- Hypothermia/vasoconstriction
- Patient use of vasoconstrictive drugs
- Jaundice

Laryngeal Mask Airway

The laryngeal mask airway (LMA) is an advanced airway control device. It may be used in the prehospital setting when conventional endotracheal intubation is unsuccessful, when access to the patient is limited, when an unstable neck injury may be present, or when appropriate positioning of the patient for tracheal intubation is impossible.[23] Some LMAs also allow endotracheal intubation through the device. This allows easier placement of the tube.

NOTE
The laryngeal mask airway (LMA) does not offer full protection against aspiration. However, aspiration is uncommon with this device. A small number of patients cannot be ventilated adequately with the LMA. Also, it is contraindicated in conscious patients and in those with an intact gag reflex.

BOX 15-13 Oxygen Saturation and Partial Pressure (PO_2)

With 90% saturation: PO_2 drops to 60 mm Hg
With 75% saturation: PO_2 drops to 40 mm Hg
With 50% saturation: PO_2 drops to 27 mm Hg

DESCRIPTION

The LMA is available in several sizes (ranging from size 1 for neonates to size 5 for adults.) It consists of a proximal tube with standard adapters for connecting ventilatory devices. The tube is connected to a distal mask that is inflated by means of a pilot tube and balloon (Figure 15-90).

INSERTION

The LMA is inserted through the mouth into the pharynx. It is advanced until resistance is felt as the distal portion of the tube locates in the hypopharynx. When the device has been properly inserted, the black line marked on the LMA rests midline against the patient's upper lip. Inflating the cuff seals the larynx and leaves the distal opening of the tube just above the glottis, providing a clear, secure airway. After the pilot cuff has been inflated, proper placement is confirmed by observing equal rise and fall of the chest, by ensuring bilateral breath sounds, and with end-tidal CO_2 detectors and pulse oximetry monitoring (in a patient who has a perfusing rhythm) (Figure 15-91). Use of the LMA requires special training and authorization from medical direction. The LMA may be difficult to maintain during patient movement, which can make it difficult to use during patient transport.

NECESSARY EQUIPMENT

- Water-soluble lubricant
- Syringes
- Bag-valve device
- Oxygen source and connecting tubing
- Suction equipment
- Stethoscope
- One or more confirmation devices

COMMON ADVANTAGES

- Less skilled training or maintenance is required than for endotracheal intubation.

FIGURE 15-90 Laryngeal mask airways.

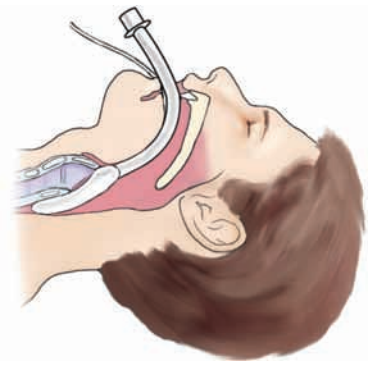

FIGURE 15-91 A patient with a laryngeal mask airway (LMA).

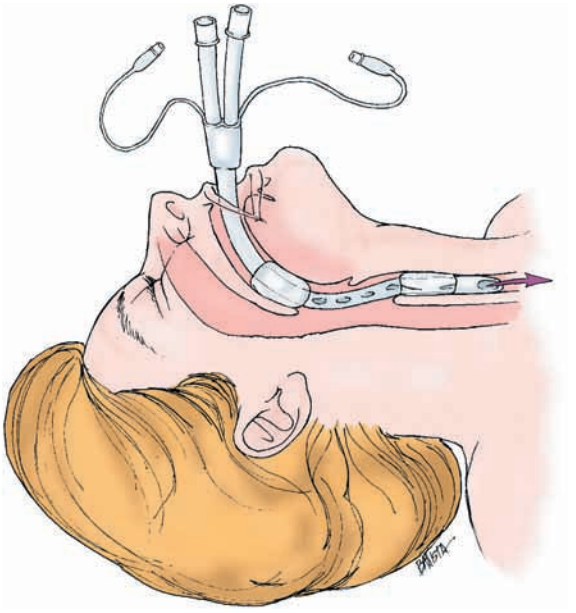

FIGURE 15-92 Placement of the esophageal-tracheal Combitube airway.

- Laryngoscopy and visualization of the vocal cords are not required.
- Minimal spinal movement is required for insertion.
- Endotracheal intubation can be achieved through some LMAs.

COMMON DISADVANTAGES

- The patient must be unresponsive and have no gag reflex.
- Not all patients can be adequately ventilated with the LMA.
- The airway must be removed when the patient becomes responsive or agitated.
- The airway does not provide as much protection from aspiration as the ET tube.

COMMON CONTRAINDICATIONS

- Presence of a gag reflex
- Caustic ingestion
- Esophageal trauma or disease

Esophageal-Tracheal Combitube

The esophageal-tracheal Combitube (ETC, Combitube) allows for either esophageal or tracheal insertion. It is a plastic tube with twin lumens that are separated by a partition wall. One tube resembles an ET tube and has an open distal end. The other tube is blocked by an obturator at the distal end. Both tubes use low-pressure balloons that provide a seal for either the trachea or the esophagus, depending on placement. There are also holes on one side of the tube between the balloons that allow for ventilation through tube 1. When inflated, the large pharyngeal balloon fills the space between the base of the tongue and the soft palate, anchoring the tube in position. The Combitube usually finds its way into the esophagus because of the stiffness and curve of the tube and the shape and the structure of the pharynx.

The Combitube is another option for airway control when endotracheal intubation is indicated but is unsuccessful or unavailable. The LMA and Combitube provide superior ventilation compared with face masks in cardiac arrest.[23] The Combitube reduces but does not eliminate the risk of aspiration. Some EMS agencies prefer the Combitube as a rescue device for endotracheal intubation because the device can be easily and quickly inserted.

INSERTION

The Combitube is inserted by gently guiding the device into the esophagus or trachea (Figure 15-92). The tube should be inserted into the midline and to a depth that puts the printed ring at the level of the teeth. (This insertion is achieved without hyperextension or flexion of the patient's head. It also is done without visualization of the glottic opening.) The pharyngeal and distal balloons then are inflated. This isolates the oropharynx above the upper balloon and the esophagus (or trachea) below the lower balloon. Ventilation is at first provided through the esophageal lumen. (This is due to the significant chance of esophageal placement with blind insertion.) In this position, air passes into the pharynx and beyond the glottis into the trachea. The placement is confirmed by the primary and secondary confirmation methods described previously.

If breath sounds and chest movement are absent with ventilation through the esophageal lumen (tube 1), ventilation should be performed through the tracheal lumen (tube 2) without changing the position of the airway. Air passes through this lumen directly into the trachea. Placement is confirmed in the usual manner.

NECESSARY EQUIPMENT

- Water-soluble lubricant
- Syringes
- Bag-mask device
- Oxygen source and connecting tubing
- Suction equipment
- Stethoscope

The various kinds of balloon-system devices share advantages, disadvantages, and contraindications.

ADVANTAGES

- Airways cannot be placed improperly.
- Less skill training or skill maintenance is needed than for endotracheal intubation.
- Minimal spinal movement is required for insertion.
- Suctioning is easily done.

DISADVANTAGES

- The patient must be unresponsive and without a gag reflex.
- The airway must be removed when the patient becomes responsive or agitated.
- Proper identification of the tube's location may be difficult, leading to ventilation through the wrong lumen.
- The trachea cannot be suctioned when the tube is in the esophagus.
- The airway should be replaced with an ET tube as soon as possible.

CONTRAINDICATIONS

- Patient height less than 5 feet or age under 14 years
- Caustic ingestion
- Esophageal trauma or disease
- Presence of a gag reflex

King LT-D Airway

The King LT-D airway is a disposable supraglottic device designed for positive pressure ventilation as well as for patients who are breathing spontaneously. It is an alternative to mask ventilation and tracheal intubation.

The King LT-D airway has a single tube that is placed only into the esophagus. (The tube's large size and short length virtually eliminates the possibility of placement into the trachea.) The tube is curved and has a proximal and distal cuff. As with the ETC, a large balloon is inflated in the oropharynx. At the same time, a smaller cuff is inflated in the esophagus by the same port that inflates the large cuff. Ventilations are delivered by attaching a bag-mask device to the proximal end of the tube. With each ventilation, the air escapes through holes in the tube between the cuffs. Some LT King-D airways also provide for passage of tubes for gastric decompression. The King LT-D is available in multiple sizes, based on a patient's height (Figure 15-93).

Use of the King LT-D airway is indicated when tracheal intubation cannot be established in two attempts *and* when a patient is unable to adequately maintain his or her airway, has an altered mental status (Glasgow Coma Score of 8 or lower), or has respiratory compromise. Contraindications to use of the airway include patients who are less than 4 feet tall, patients who have an intact gag reflex, patients who have ingested caustic substances, and patients with known esophageal disease.

Before the airway is inserted, the cuff should be tested for integrity and then deflated (Figure 15-94). Lubricant is applied to the back side of the airway, with care taken not to clog the holes in the tube. The patient's head should be placed in a neutral position, observing spinal precautions if indicated. Before insertion, the patient's lungs are preoxygenated with 100% oxygen. The patient's mouth should be opened, using a head-tilt or chin-lift maneuver. The tube is advanced gently behind the base of the patient's tongue while the tube is rotated back to the midline. The tube's blue orientation line should face the patient's chin. The tube then is gently advanced until the base of the connector is aligned with the patient's teeth or gums. The airway is inflated with the appropriate volume of air.

The bag-mask device is connected to the adaptor on the tube, and ventilations are provided. While providing ventilations, the paramedic gently withdraws the tube until ventilation compliance becomes easy and free flowing. Cuff inflation may be adjusted if necessary to maintain a seal of the airway at the peak ventilatory pressure used. Correct placement is confirmed by listening for breath sounds, observing chest rise and fall, the presence of $EtCO_2$, and a stable or rising SpO_2. Equal and bilateral breath sounds should be confirmed. The device is secured, and placement of a bite block should be considered.

The position of the King LT-D airway should be rechecked after each patient movement, on transfer of care to another provider, and after an ascent or a descent of more than 1000 feet.

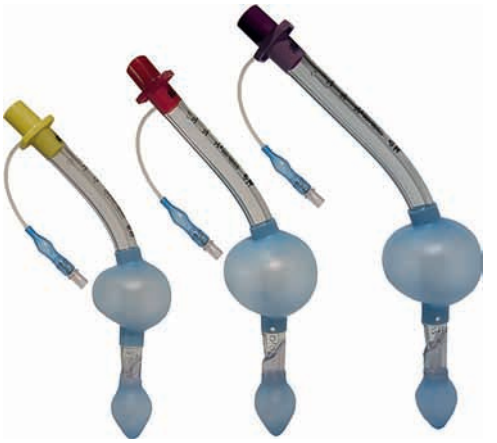

FIGURE 15-93 King LT-D airways. (Henry MC, Stapleton ER: *EMT prehospital care,* ed 4, St Louis, 2009, Mosby.)

NOTE
The King LT-D airway may be considered *before* tracheal intubation if significant access issues exist (e.g., prolonged entrapment) or if a difficult intubation is anticipated.

PHARMACOLOGICAL ADJUNCTS TO AIRWAY MANAGEMENT AND VENTILATION

Sedation sometimes is used in airway management and ventilation to reduce anxiety, induce amnesia, and decrease the gag reflex. Possible indications for sedation include combative patients, patients who require aggressive airway management but who are too alert to tolerate intubation, and agitated trauma patients. The classes of drugs commonly used for sedation in these situations are tranquilizers, barbiturates, benzodiazepines, and narcotics. Two medications commonly used for drug-assisted intubation are ***midazolam*** (a short-acting benzodiazepine) and ***etomidate*** (a nonbarbiturate hypnotic).

NOTE
Sedating a patient with a poor airway is dangerous. The patient may suffer respiratory arrest. The paramedic must always consult medical direction.

NOTE
Paralyzing a patient for intubation is controversial. If permitted by state EMS law, the procedure requires advanced training and authorization from medical direction.

Paralytic Agents in Emergency Intubation

Although controversial, paralysis may be used for emergency intubation. Paralysis involves the use of neuromuscular blocking drugs. These drugs are indicated for combative patients who need to be intubated. For instance, a patient suffering a head injury may be agitated and combative. These drugs should not be used in the following situations:

- Patients who will be difficult to ventilate (e.g., patients with facial hair)
- Patients who will be difficult to intubate (e.g., patients with short necks, obstructions)

PHARMACOLOGY

As described in Chapter 13, neuromuscular blockers produce skeletal muscle paralysis. They do this by binding to the nicotinic receptor for acetylcholine (ACh) at the neuromuscular junction. To review, this junction is the point of contact between the nerve ending and the muscle fiber (see Chapter 10). When nerve impulses pass through this junction, ACh and other chemicals are released. This release causes the muscle to contract. The two types of neuromuscular blocking drugs are depolarizing agents and nondepolarizing agents. Neuromuscular blockers should not be administered to patients until sufficient sedation has been achieved.

TABLE 15-7 Drugs Commonly Used for Pharmacologically Assisted Intubation

Drug	Dose (Adult) IV/IO	Dose (Pediatric) IV/IO	Indications	Complications/Side Effects
Pretreatment				
Oxygen	High flow Assist ventilation as needed to achieve oxygen saturation of 100% if possible	High flow Assist ventilation as needed to achieve oxygen saturation of 100% if possible	All patients undergoing pharmacologically assisted intubation	—
Lidocaine	1-2 mg/kg	1-2 mg/kg	Brain injury	Seizure
Atropine	—	0.01-0.02 mg/kg **(minimum dose, 0.1 mg; maximum dose, 0.5 mg)**	Pediatric intubation, prevention of bradycardia and excess secretions	Tachycardia
Induction of Sedation				
Midazolam (Versed)	0.1-0.3 mg/kg (maximum single dose, 10 mg)	0.1-0.3 mg/kg (maximum single dose, 10 mg)	Sedation	Respiratory depression/apnea, hypotension
Fentanyl (Sublimaze)	2-5 mcg/kg	2-5 mcg/kg	Sedation	Respiratory depression/apnea, hypotension, bradycardia
Etomidate	0.2-0.4 mg/kg (limit 1 dose; consider cortisone stress doses for a patient in shock)	0.2-0.4 mg/kg	Sedation, induced anesthesia	Apnea, hypotension, vomiting
Chemical Paralysis				
Succinylcholine	1-1.5 mg/kg	1-1.5 mg/kg	Muscle relaxation and paralysis (short duration)	Hyperkalemia, muscle fasciculations

LOOK AGAIN
See Chapter 10: Review of Human Systems, p. 311.

NOTE
Rapid sequence intubation (RSI) is not within the national scope of practice of the paramedic. Special training, credentialing, and authorization from medical direction are required in most states.

Depolarizing agents invade the neuromuscular junction and bind to the receptors for ACh. These drugs produce depolarization of the muscular membrane. Thus they often lead to fasciculations (uncontrollable muscle twitching). These drugs also may lead to some muscular contractions. An example of a depolarizing agent is ***succinylcholine.*** Succinylcholine has a rapid onset of action. Yet it has the briefest duration of action of all the neuromuscular blocking drugs. This makes it the drug of choice for emergency endotracheal intubation.

Nondepolarizing agents also bind to the receptors for ACh. However, they block the uptake of ACh at the neuromuscular junction without initiating depolarization of the muscle membrane. Examples of nondepolarizing drugs include ***vecuronium*** and ***rocuronium.*** These drugs have a longer onset and duration than depolarizing agents.

Neuromuscular blocking agents produce complete paralysis. Consequently, ventilatory support must be provided. Ventilation and oxygenation must be closely monitored to ensure that they are adequate. If the patient is conscious, the paramedic should explain the effects of the medication before administering it. Administration of ***atropine*** should be strongly considered, particularly in children, before a neuromuscular blocking agent is administered. ***Lidocaine*** given before administration of a neuromuscular blocking agent may blunt any increase in intracranial pressure associated with intubation. Finally, ***diazepam, etomidate, midazolam,*** or another sedative approved by medical direction should be used in any conscious patient to whom a blocking agent is administered; neuromuscular blocking agents do not inhibit pain or seizure activity (Table 15-7).

Rapid Sequence Intubation

Rapid sequence intubation (RSI) involves the administration of a potent sedative and a neuromuscular blocking agent at the same time to achieve optimal intubation conditions in less than 1 minute.[34] The blocking agent most often used is ***succinylcholine*** (see the Emergency Drug Index (EDI)). In addition to providing optimal intubation conditions, RSI also minimizes the risk of aspiration of gastric contents. RSI is indicated in the following situations[35]:

- Emergency intubation is warranted.
- The patient has a "full" stomach.
- Intubation is predicted to be successful (i.e., the patient does not have a difficult airway) (Box 15-14).
- If intubation fails, ventilation is predicted to be successful.

RSI is not indicated for patients in cardiac arrest or for deeply comatose patients when immediate intubation is required. Relative contraindications include concern that intubation or mask ventilation would be unsuccessful; significant facial or laryngeal edema, trauma, or distortion; or a spontaneously breathing patient who requires upper airway muscle tone and positioning (e.g., upper airway obstruction, epiglottitis).[23]

RSI is an organized approach to endotracheal intubation. It involves specific steps and actions that lead to rapid sedation and paralysis without positive pressure ventilation once the procedure begins. The purpose of RSI is to achieve optimum and rapid tracheal intubation in patients at risk for aspiration. The procedure is intended to take the patient from a conscious, breathing state to a state of unconsciousness. This is accomplished with complete neuromuscular paralysis. Intubation is performed without interposed mechanical ventilation. The six steps of RSI (the six *P*s) are preparation, preoxygenation, pretreatment, paralysis (with sedation), placement of the tube, and postintubation management (Boxes 15-15 and 15-16).

TECHNIQUE

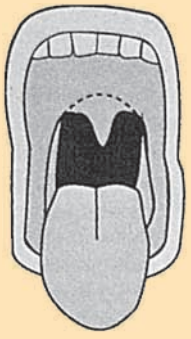
1. **Preparation**
   - Assess the patient for difficulty of intubation (e.g., using the Mallampati score [see Box 15-14]).
   - Prepare all drugs and equipment.
   - Make sure the patient has one or more patent IV lines.
   - Explain the procedure to the patient.
2. **Preoxygenation (done simultaneously with preparation)**
   - Preoxygenate the patient with 100% oxygen for 5 minutes (an essential step of the "no bagging" approach of RSI).
   - Consider using a pulse oximeter.
3. **Pretreatment (done 3 minutes before intubation)**
   - Consider giving ***lidocaine*** to protect against a rise in intracranial pressure and to prevent laryngospasm.
   - Consider giving beta blockers or opioids to reduce a sympathoadrenal response (e.g., a drop in blood pressure) to intubation.
4. **Paralysis (with sedation)**
   - Administer a sedative (per protocol) to produce unconsciousness. This should be immediately followed by a rapid push of the neuromuscular blocker (see the EDI).
   - Apply cricoid pressure as the patient loses consciousness to prevent vomiting. (Once neuromuscular blockade has been established, active vomiting cannot occur.)
   - Do not initiate ventilations unless the patient's oxygen saturation falls below 90%.

BOX 15-14 Difficult Airway

A "difficult airway" can be defined as a clinical situation in which an experienced practitioner has difficulty with mask ventilation, tracheal intubation, or both. The airway should be examined before airway management in all patients. This is done to identify physical characteristics that may indicate the presence of or potential for a difficult airway. Paramedics should assess the following airway features.[36]

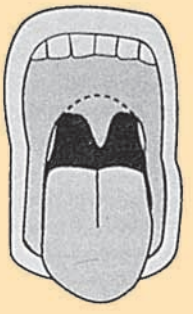
Feature	Sign of Difficult Airway
Length of upper incisors	Relatively long
Relation of maxillary and mandibular incisors with normal jaw closure	Prominent overbite
Visibility of uvula	Not visible when tongue is protruded (e.g., > Mallampati class II)
Shape of palate	Highly arched or very narrow
Length of neck	Short
Thickness of neck	Thick
Range of motion of head and neck	Patient cannot touch tip of chin to chest or extend neck.

Mallampati Signs as Indicators of Difficult Intubation



Class I: soft palate, uvula, fauces, pillars visible

No difficulty



Class II: soft palate, uvula, fauces visible

No difficulty

Class III: soft palate, base of uvula visible

Moderate difficulty

Class IV: hard palate only visible

Severe difficulty

Mallampati Signs as Indicators of Difficult Intubation

Class I (soft palate, uvula, fauces, pillars visible)—No difficulty
Class II (soft palate, uvula, fauces visible)—No difficulty
Class III (soft palate, base of uvula visible)—Moderate difficulty
Class IV (hard palate only visible)—Severe difficulty

The following also may be indicators of a potentially difficult Airway:

- An immobilized trauma patient
- Morbidly obese patient
- Children
- Limited jaw opening
- Upper airway conditions (e.g., burns, neck injury, epiglottitis)
- Facial trauma
- Laryngeal trauma

If a difficult airway is evident, advanced airway management is required, as presented in the algorithm in Figure 15-95.

CRITICAL THINKING

How would you decide whether a patient needs more sedation after a paralytic has been given?

BOX 15-15 Six *Ps* of Rapid Sequence Intubation

1. Preparation
2. Preoxygenation
3. Pretreatment
4. Paralysis (with sedation)
5. Placement of the tube
6. Postintubation management

- Within 45 seconds of administration of ***succinylcholine,*** the patient will be relaxed enough for intubation.

5. **Placement**
   - Perform orotracheal intubation and confirm proper placement of the tube.
6. **Postintubation management**
   - Secure the tube in place.
   - Begin mechanical ventilation.
   - Monitor the patient continuously.

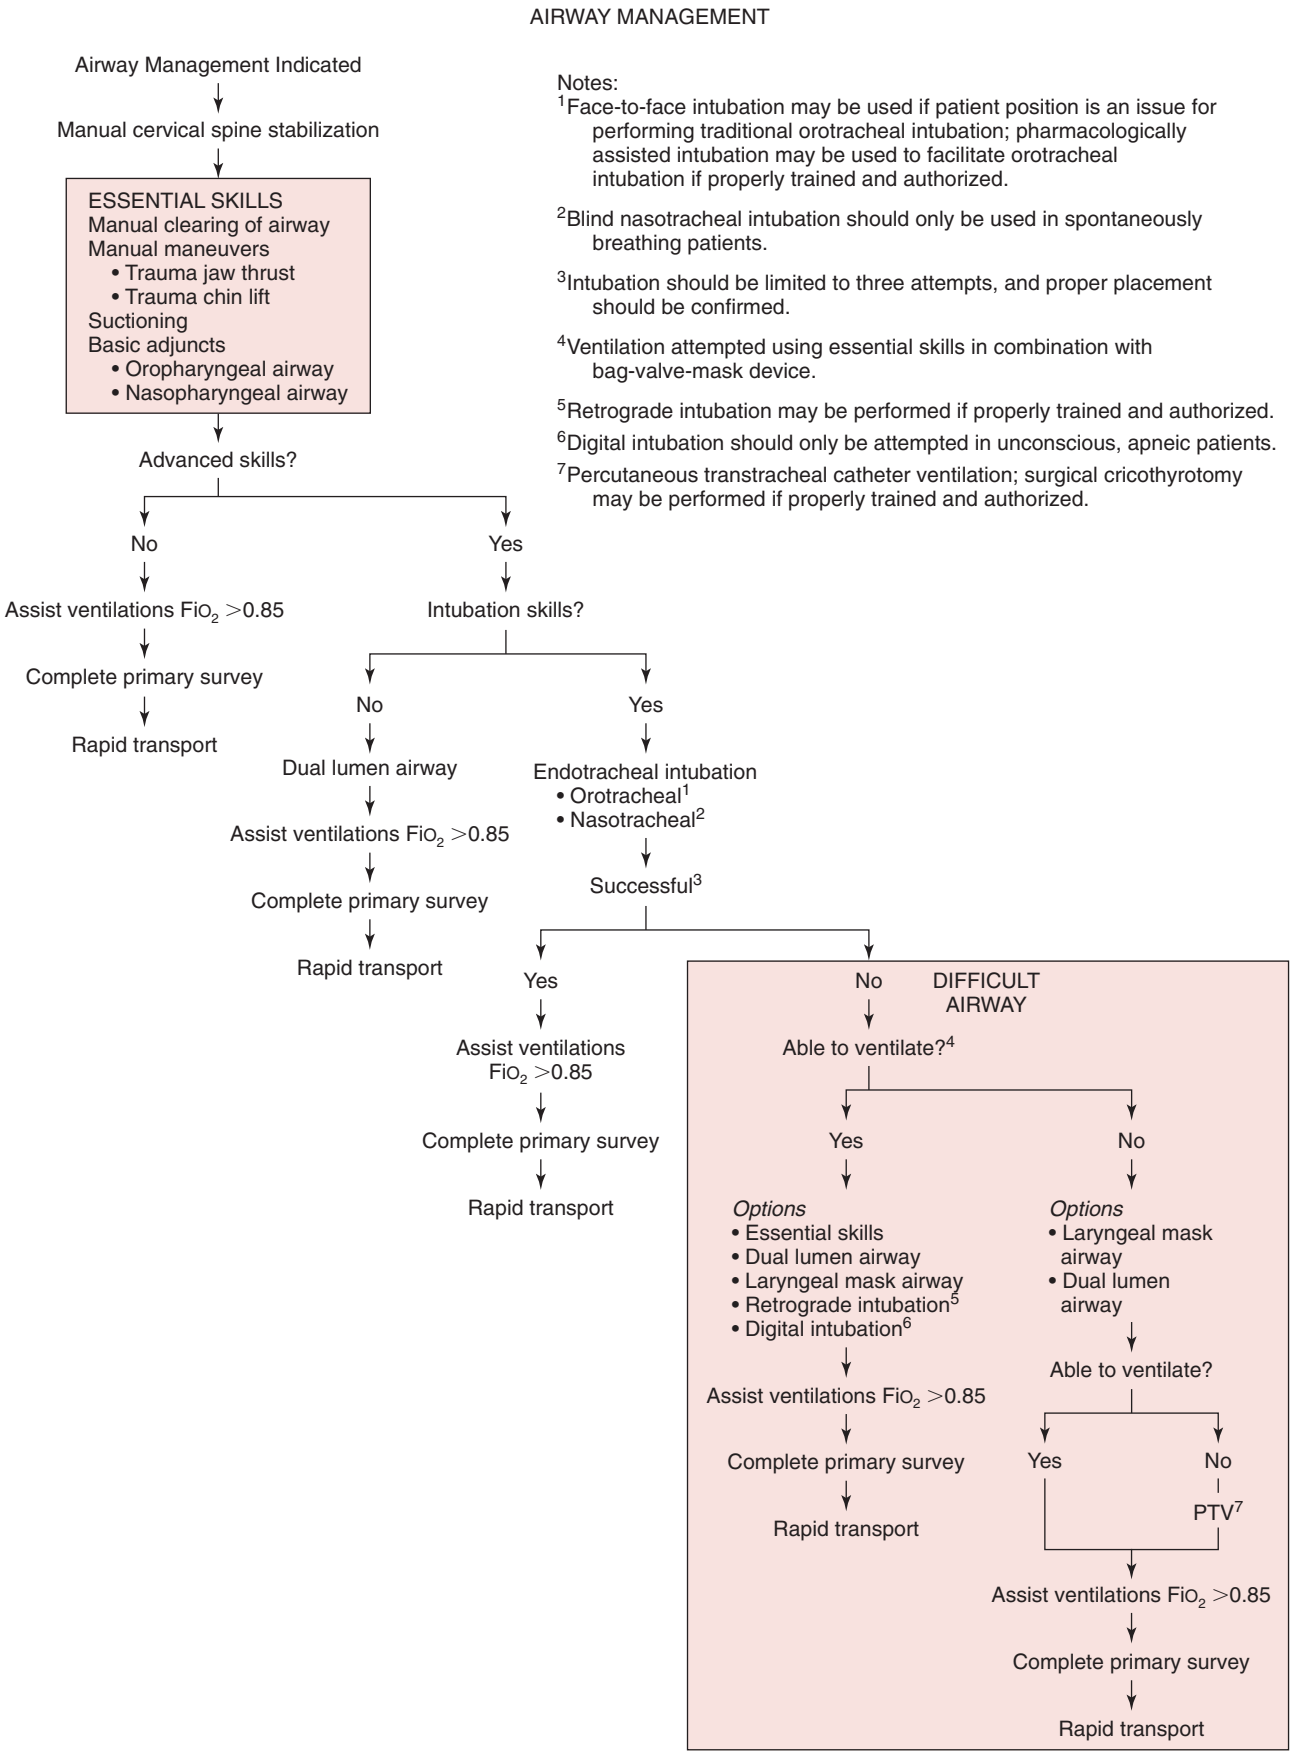


FIGURE 15-95 Difficult airway algorithm. (NAEMT: *Prehospital trauma life support,* ed 7, St Louis, 2011, Mosby.)

BOX 15-16 Sample Protocol for Rapid Sequence Intubation (RSI)

1. Make sure the required equipment is available.
   - Oxygen supply
   - Bag-mask of appropriate size and type
   - Nonrebreathing mask
   - Laryngoscope with blades
   - Endotracheal (ET) tubes
   - Gum elastic bougie
   - Surgical and alternative airway equipment
   - RSI medications
   - Materials or devices to secure ET tube after placement
   - Suction equipment
2. Make sure at least one patent intravenous (IV) line is present (two are preferable).
3. Preoxygenate the patient using a nonrebreathing mask or bag-mask with 100% oxygen. Preoxygenation for 3 to 4 minutes is preferred.
4. Apply cardiac and pulse oximetry monitors.
5. If the patient is conscious, strongly consider the use of sedative agents.
6. Consider administration of sedative agents and lidocaine if potential or confirmed traumatic brain injury (TBI) is a factor.
7. After administration of paralytic agents, use the Sellick maneuver (cricoid pressure) to reduce the potential for aspiration.
8. Confirm tube placement immediately after intubation. Continuous cardiac and pulse oximeter monitoring is required during and after RSI. Reconfirm tube placement periodically throughout transport and each time the patient is moved.
9. Use repeat doses of sedative and paralytic agents as needed.

Procedure

1. Assemble the required equipment.
2. Make sure the IV lines are patent.
3. Preoxygenate the patient with 100% oxygen for approximately 3 to 4 minutes if possible.
4. Place the patient on cardiac and pulse oximeter monitors.
5. Administer a sedative (e.g., midazolam) if appropriate.
6. If TBI is possible or has been confirmed, administer lidocaine (1.5 mg/kg) 2 to 3 minutes before administration of a paralytic agent.
7. For pediatric patients, administer atropine (0.01-0.02 mg/kg) 1 to 3 minutes before paralytic administration to minimize the vagal response to intubation.
8. Administer a short-acting paralytic agent (e.g., succinylcholine) intravenously. Paralysis and relaxation should occur within 30 seconds. Using the Sellick maneuver may also be helpful.
   - Adult dosage: 1 to 2 mg/kg
   - Pediatric dosage: 1 to 2 mg/kg
9. Insert an ET tube. If initial attempts are unsuccessful, precede repeat attempts with preoxygenation.
10. Confirm ET tube placement.
11. If repeated attempts to achieve endotracheal intubation fail, consider placement of an alternative or surgical airway.
12. Use a long-acting paralytic agent (e.g., vecuronium) to continue paralysis.
    - Initial dose: 0.1 mg/kg IV push
    - Subsequent doses: 0.01 mg/kg every 30 to 45 minutes
13. Repeat doses of sedative medications also may be needed.

Note: Requirements vary with individual patients.
From: *American College of Surgeons Committee on Trauma, Prehospital Trauma Life Support,* ed 7, St. Louis, 2011, Elsevier.

If RSI is unsuccessful and the patient cannot be intubated, the airway should be managed by other means (e.g., ETC, bag-mask device, or cricothyrotomy).

Note: ***Succinylcholine*** directly depolarizes all motor end plates, simultaneously causing fasciculations and a rise in these pressures. Premedication with ***vecuronium,*** administered in a dosage of 0.01 mg/kg, can prevent these pressure rises[34] (see the EDI).

TRANSLARYNGEAL CANNULA VENTILATION

Translaryngeal cannula ventilation is also known as *percutaneous transtracheal ventilation* and *needle cricothyrotomy*. It may be valuable in the initial stabilization of a patient whose airway cannot be managed by the usual manual measures. It also may be valuable in patients who cannot be intubated by oral or nasal means or who have complete airway obstruction. It is a temporary procedure. It provides oxygenation when the airway is obstructed as a result of edema of the glottis, fracture of the larynx, or severe oropharyngeal hemorrhage. Translaryngeal cannula ventilation requires special training and authorization from medical direction.

Description

Translaryngeal cannula ventilation provides high-volume, high-pressure oxygenation of the lungs. This occurs through cannulation of the trachea below the glottis. The procedure delivers a large volume of oxygen through a small port at high pressure to the lungs. This oxygen delivery (50 psi) is much greater than can be achieved with other methods (e.g., 1 psi with a therapy regulator).

Necessary Equipment

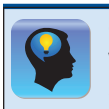
- A 12- or 14-gauge over-the-needle catheter with a 5 or 10 mL syringe
- Alcohol or povidone-iodine swabs
- Adhesive tape or appropriate ties
- Pressure-regulating valve and pressure gauge attached to a high-pressure (30 to 60 psi) oxygen supply. (Most oxygen tanks and regulators can provide 50 psi at 15 L/minute or when opened to flush.)
- High-pressure tubing connecting the high-pressure regulating valve to a hand-operated release valve (5-foot tubing is recommended).
- A release valve connected by tubing to the catheter (this may be provided via a Y- or T-connector, through a

three-way stopcock directly attached to the high-pressure tubing, or by cutting a hole in the oxygen line to provide a "whistle stop" effect).

Technique

The steps in translaryngeal cannula ventilation are as follows (Figure 15-96):

1. Make sure the patient is supine. Also make sure the cricothyroid membrane has been identified. (If a spinal injury is suspected, in-line stabilization may be provided as for nasal and tracheal intubation.)
2. Stabilize the larynx using the thumb and middle finger of one hand. With the other hand, palpate the small depression below the thyroid cartilage (the Adam's apple). Slide the index finger down to locate the cricothyroid membrane.
3. Insert the needle of the syringe downward through the midline of the membrane at a 45- to 60-degree angle toward the patient's carina. Apply negative pressure to the syringe during insertion. The entrance of air into the syringe indicates that the needle is in the trachea (Figure 15-97, *A*).
4. Advance the catheter over the needle toward the carina and remove the needle and syringe (Figure 15-97, *B*). Take care not to kink the catheter when removing the needle and syringe.
5. Hold the hub of the catheter to prevent accidental dislodgement while providing ventilation. Remove the end of the oxygen tubing from the hub of the cannula and connect it to the oxygen regulator. Provide for a release valve as described previously.



CRITICAL THINKING

What conditions could make it difficult to locate the anatomical landmarks for translaryngeal cannulation or cricothyrotomy?

When the release valve is closed, oxygen under pressure is introduced into the trachea. The pressure is adjusted to a level that allows adequate lung expansion. The patient's chest must be observed closely. The release valve must be opened to allow for exhalation. The correct ratio of inflation to deflation varies, depending on whether upper airway obstruction is present. For an open upper airway, an

FIGURE 15-96 Translaryngeal cannula ventilation. **A**, Stabilize the larynx and identify the cricothyroid membrane. **B**, Insert the needle of the syringe downward through the midline of the membrane toward the carina. **C**, While inserting the needle, draw back on the plunger of the syringe. If air enters the syringe, the needle is in the trachea. **D**, After removing the needle and syringe, stabilize the catheter and connect the end of the oxygen tubing from the hub of the cannula to the oxygen regulator. Provide for a release valve.

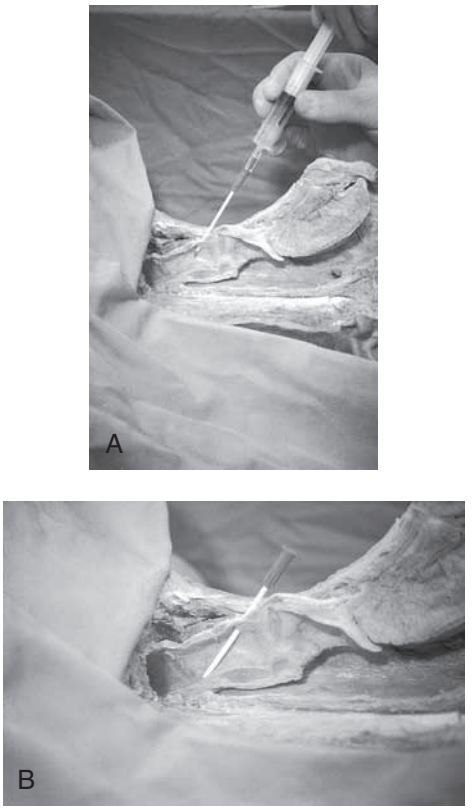


FIGURE 15-97 **A,** Insert a large-bore catheter through the cricothyroid membrane, directing it toward the feet. While inserting the catheter, draw back on the plunger of the syringe; when air enters the syringe, the needle is in the airway. **B,** Slide the catheter off the stylet into the larynx.

inspiratory to expiratory ratio of 1 to 4 seconds is adequate. A ratio of about 1 to 8 seconds is needed to prevent barotrauma (injuries caused by excessive pressures [e.g., pneumothorax]) when the upper airway is obstructed.[37]

NOTE
If the chest remains inflated during exhalation, a complete upper airway obstruction may be present. In such cases a longer expiratory time should be allowed. If this does not produce adequate deflation, a second large-bore catheter may be inserted through the cricothyroid membrane next to the first one. If the chest remains distended, a cricothyrotomy should be performed.

Advantages

- Translaryngeal cannula ventilation is the least invasive of surgical procedures.
- It can be initiated quickly.
- When performed by a trained paramedic, it is simple, inexpensive, and effective.
- Minimal spinal movement is needed for insertion.

Disadvantages

- The technique is an invasive procedure.
- Constant monitoring is required.
- Jet ventilation is required
- The airway is not protected.
- The procedure does not allow for efficient elimination of carbon dioxide.
- The patient's lungs can be ventilated adequately only for 30 to 45 minutes.

Possible Complications

- High pressure during ventilation and air entrapment may cause pneumothorax.
- Hemorrhage may occur at the insertion site. The thyroid and esophagus also may be perforated if the needle is advanced too far.
- Direct suctioning of secretions is impossible.
- Subcutaneous emphysema may occur.

Removal

Translaryngeal cannula ventilation is a temporary emergency procedure. It provides time for the use of other airway management techniques. The catheter should be removed only after successful orotracheal or nasotracheal intubation or after a cricothyrotomy or a tracheostomy has been performed. Removal involves withdrawing the catheter and dressing the wound.

CRICOTHYROTOMY

Cricothyrotomy is a surgical procedure. It allows rapid entrance to the airway through the cricothyroid membrane. The procedure can be performed quickly. It is much faster and easier than a tracheostomy. In addition, it does not require manipulation of the cervical spine.

Description

Cricothyrotomy can provide ventilation and oxygenation when airway control is not possible by other means. It should not be performed on patients who can be orally or nasally intubated. Few situations require this surgical procedure. Relative indications for cricothyrotomy include severe facial or nasal injuries that preclude oral or nasal intubation, massive midfacial trauma, possible spinal trauma preventing adequate ventilation, anaphylaxis, and chemical inhalation injuries. Like translaryngeal cannula ventilation, cricothyrotomy requires special training and authorization from medical direction.

NOTE
Remember: Cricothyrotomy should be considered *only when you cannot intubate AND cannot ventilate*. If you cannot intubate but you *can* ventilate—do not cut the neck.

Necessary Equipment

Commercially prepared cricothyrotomy kits are available through a number of manufacturers (Figure 15-98). If such a kit is not available, the following equipment is required:

- Scalpel blade
- Size 6 (preferred) or size 7 ET tube or tracheostomy tube

- Antiseptic solution
- Oxygen source
- Suction device
- Bag-valve device

Technique

In patients suspected of having a spinal injury, in-line stabilization should be maintained throughout the procedure. If possible, the neck should be cleaned with alcohol or another antiseptic solution. The steps in the surgical procedure are as follows (Figure 15-99):

1. Locate the anatomical landmarks of the neck. Identify the cricothyroid membrane.
2. Make a 2 cm (¾ inch) horizontal incision with the scalpel at the level of the cricothyroid membrane. (Some physicians may recommend a vertical skin incision instead of a horizontal one.)
3. Open the incision in the cricothyroid membrane by inserting the scalpel handle. Rotate it 90 degrees. This allows placement of a size 6 or size 7 ET tube or tracheostomy tube, which will not damage the larynx. The cuff should be inflated and the tube tied securely.
4. Provide ventilation by a bag-mask device with the highest available oxygen concentration.
5. Determine the adequacy of ventilation. This can be done through bilateral auscultation and observation of rise and fall of the chest.
6. Use a secondary confirmation method such as end-tidal CO_2.

NOTE
Use of a smaller diameter endotracheal (ET) tube may aid successful placement. Once the tube is in the airway, the paramedic should be careful not to advance it more than a few centimeters. This helps prevent mainstem intubation.

Possible Complications

- Prolonged procedure time
- Hemorrhage

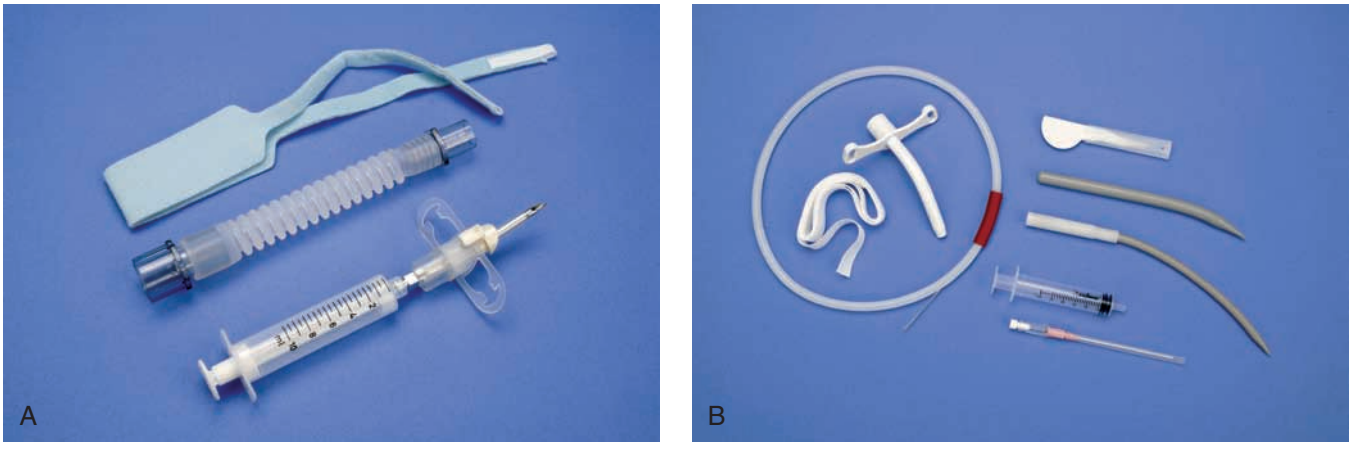

FIGURE 15-98 Commercial cricothyrotomy kits.

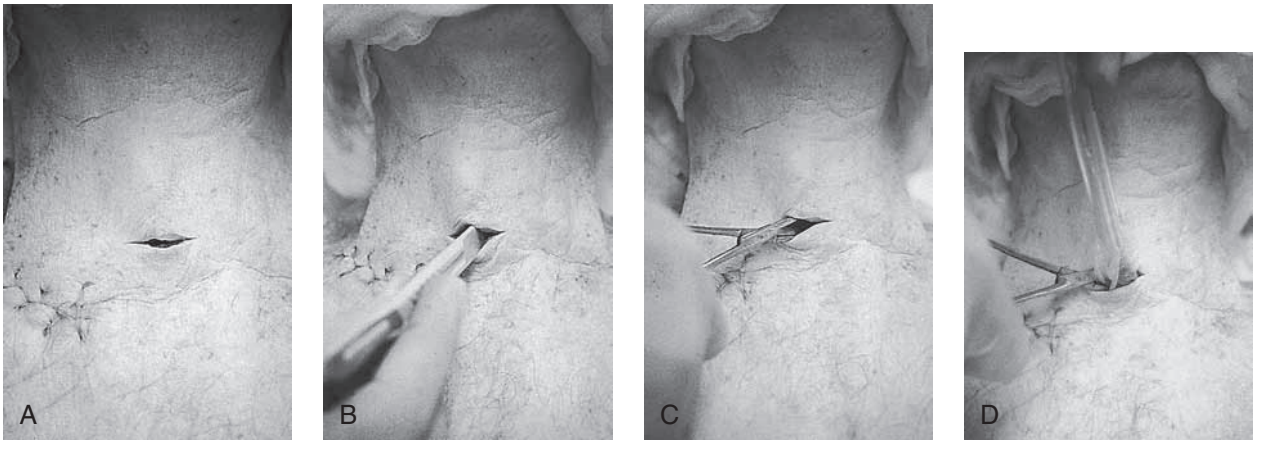

FIGURE 15-99 Surgical cricothyrotomy. **A**, Make an incision through the cricothyroid membrane. **B**, Open the hole by twisting the handle of a scalpel in it, *or* **C**, Open the hole with a clamp. **D**, Insert the endotracheal (ET) tube.

- Aspiration
- Possible misplacement
- False passage
- Perforation of the esophagus
- Injury to the vocal cords and carotid and jugular vessels lateral to the incision (the patient must be immobilized)
- Subcutaneous emphysema

Contraindications

- Inability to identify anatomical landmarks
- Underlying anatomical abnormality (e.g., tumor, subglottic stenosis)
- Tracheal transection
- Acute laryngeal disease caused by trauma or infection
- Small child under 10 years of age (in these patients, insertion of a 12- to 14-gauge catheter over the needle may be safer than a cricothyrotomy)

Removal

In the prehospital setting, no attempt should be made to remove ET tubes used during an emergency cricothyrotomy.

SUMMARY

- The upper airway opens at the nose and mouth and extends to the glottic opening.
- Structures of the lower airway include the trachea, right and left bronchus, bronchi, bronchioles, and the functional units of the lungs, the alveoli.
- The base of the lungs rests on the diaphragm. The right lung has three lobes and the left has two.
- The primary muscles of ventilation are the diaphragm and the intercostal muscles.
- The phrenic nerve enervates the diaphragm.
- *Respiration* is the exchange of oxygen and carbon dioxide between an organism and the environment. *Pulmonary ventilation* involves the movement of gas into and out of the lungs.
- *External respiration* is the transfer of gases between the inspired air and pulmonary capillaries. *Internal respiration* is the transfer of gases between the blood and tissue cells.
- During inspiration, the size of the thoracic cavity increases. This creates negative pressure inside the chest relative to atmospheric pressure, so air rushes into the lungs.
- During exhalation the chest muscles relax passively, and air is forced out of the lungs.
- The work of breathing increases if surfactant is lost, airway resistance increases, or pulmonary compliance decreases.
- The normal adult respiratory rate is 12 to 24 breaths/minute.
- No gas exchange occurs in the anatomical dead space. The physiological dead space includes the anatomical dead space plus any nonfunctioning alveoli.
- *Tidal volume* is the amount of gas inhaled or exhaled with each normal breath.
- The respiratory rate multiplied by the tidal volume equals the minute volume.
- Atmospheric gas contains approximately 79% nitrogen, 21% oxygen, and less than 1% carbon dioxide.
- As the pulmonary capillaries pass the alveoli, carbon dioxide diffuses into the alveoli and oxygen diffuses into the pulmonary capillaries.
- Oxygen is carried in the blood on hemoglobin. A small amount is also dissolved in the plasma. The amount of oxygen dissolved in the blood influences the extent to which oxygen binds with hemoglobin. The normal partial pressure of arterial blood oxygen (PaO_2) is 80 to 100 mm Hg. Venous PO_2 in the lungs is only 40 mm Hg; as a result, oxygen diffuses easily from the alveoli into the pulmonary capillaries.
- The respiratory centers normally are controlled by the pH of body fluids, which is influenced by carbon dioxide levels. Oxygen plays a role in the regulation of breathing in abnormal situations.
- Body temperature, medications, pain, emotion, and sleep also influence breathing.
- Modified forms of respiration are protective and include coughing, sneezing, and sighing.
- Older adults experience changes in ventilation and respiration that lead to a gradual decline in PO_2.
- Respiratory compromise and hypoxia can be caused by interruption of nervous control, structural damage to the thorax, bronchoconstriction, disruption of airway patency, oxygen deprivation, environmental factors, changes in alveolar-capillary gas exchange, ventilation deficiencies, decreases in lung compliance, ventilation/perfusion mismatching, disrupted oxygen transport, disrupted circulation, or cellular disruptions.
- Upper airway obstruction can rapidly cause death if not corrected.
- *Aspiration* is the inhalation of food, fluid, or foreign bodies into the lungs. This can cause airway obstruction and chemical damage with collapse of alveoli.
- The paramedic must assess the rate, regularity and rhythm of breathing. Also note the patient's position,

color, and heart rate. A thorough patient history should be obtained.

- Respiratory distress may be caused by upper or lower airway obstruction, inadequate ventilation, impairment of the respiratory muscles, ventilation/perfusion mismatching, diffusion abnormalities, or impairment of the nervous system.
- Supplemental oxygen is administered to increase the oxygen content in pulmonary capillaries and to help the patient compensate.
- Oxygen gas is administered by a variety of devices that regulate the concentration of oxygen delivered to the patient.
- Patient ventilation is provided by several methods, including rescue breathing (mouth to mouth, mouth to nose, mouth to stoma), mouth-to-mask breathing, bag-mask devices, and automatic transport ventilators.
- Airway management should progress from the least to most invasive methods. Airway management begins with manual maneuvers.
- Oropharyngeal or tracheal suction is used to remove liquids and foreign objects from the airway.
- Gastric distention can impair ventilation, and it increases the risk of aspiration. Orogastric or nasogastric tubes are inserted to reduce gastric distention.
- After manual airway maneuvers have been performed, mechanical adjuncts can be used to maintain the airway. Nasopharyngeal airways are used to maintain the airway in patients with a gag reflex. An oropharyngeal airway is inserted in patients with no gag reflex.
- Advanced airways include those that intubate the trachea and peritracheal airways, such as the laryngeal mask airway (LMA), King LT-D airway, and esophageal-tracheal Combitube (ETC) airway.
- Endotracheal intubation permits direct ventilation of the trachea, protection against aspiration, and a route for administering some medications. The ET tube may be inserted orally or nasally (in breathing patients). Adjuncts to assist with intubation include the stylet, tube introducer (bougie), and Magill forceps.
- It is essential to confirm proper placement of the ET tube. Methods of confirmation include auscultation of breath sounds; absence of gastric sounds; use of an esophageal detector device, and measurement of the end-tidal carbon dioxide and oxygen saturation.
- The laryngeal mask airway is inserted blindly into the hypopharynx in unresponsive patients with no gag reflex.
- An esophageal-tracheal Combitube is a twin-lumen airway placed blindly in unconscious patients with no gag reflex. In most cases the distal lumen is positioned in the esophagus, and inflation of balloons in the hypopharynx permits ventilation through tube 1. In rare cases, when the distal lumen is positioned in the trachea, the patient is ventilated through tube 2.
- Sedation sometimes is used in airway management and ventilation to reduce anxiety, induce amnesia, and decrease the gag reflex.
- In some EMS systems, neuromuscular blocking agents are used with sedation to permit endotracheal intubation.
- When an airway cannot be introduced through the nose or mouth and the patient cannot be ventilated, translaryngeal cannula ventilation or cricothyrotomy may be performed to access the airway by creating an opening in the cricothyroid membrane in the neck.

PART FIVE

Patient Assessment

Chapter 16: Scene Size-Up
Chapter 17: Therapeutic Communications
Chapter 18: History Taking
Chapter 19: Primary Assessment
Chapter 20: Secondary Assessment
Chapter 21: Clinical Decision Making

CHAPTER

16 Scene Size-Up

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the purpose of scene size-up.
2. Outline the components of scene size-up.
3. Recognize factors that may contribute to an unsafe scene.
4. Describe scene evaluation techniques.
5. Identify steps in scene management.
6. Outline measures to lower the risks associated with illness or injury at an unsafe scene.
7. Identify additional resources that may be needed to manage multiple patient incidents.

KEY TERMS

mechanism of injury The nature of the force that produced physical injury.

nature of the illness The principal characteristics and causes of an illness.

personal protective equipment Clothing or specialized equipment that provides some protection to the wearer.

safe holding area An area away from the emergency scene that provides for safety.

scene size-up An assessment of the scene to ensure scene safety for the paramedic crew, patient(s), and bystanders; a quick assessment to determine the resources needed to manage the scene adequately

Scene safety is always a priority in any EMS response.[1] This chapter provides a basic overview of scene safety. It also emphasizes the importance of personal safety for both the paramedic and the patient. From Rick Brady

SCENE SIZE-UP

Scene size-up refers to a quick assessment of an emergency scene. The purpose of the assessment is to determine what resources are needed to safely manage the event. Scene size-up is a continuous evaluation of the scene that begins when the call is received. It requires quickly gathering facts about the situation, analyzing the problems and potential problems, and determining the appropriate response.

NOTE
The paramedic must be constantly alert to situations that may change the needs of a particular incident. Scene size-up continues until the incident has been successfully managed and completed.

When a call is received for an emergency response, the paramedic should obtain as much information from the dispatcher as possible. Information from the dispatch center that will help in scene size-up includes:

- Exact location
- Type of occupancy (e.g., manufacturing, roadway, residence)
- Number of patients
- Type of situation (e.g., medical, trauma, vehicle collision)

BOX 16-1 Other Resources to Safely Manage a Scene

Special equipment for extrication and fire suppression
Additional medical supplies and equipment
Helicopter rescue
Specialized rescue teams
Hazmat decontamination
Traffic and crowd control
Public safety
Animal control
Additional lighting
Hospital availability and personnel
Public health resources

- Hazards on the scene
- Unique issues (e.g., key boxes, known medical or access problems)

Obtaining this information and regular updates from the dispatch center will help the paramedic determine the need for additional resources. These resources may include additional ambulances, fire-rescue services, mutual aid, utility services (e.g., electrical power lines and gas lines), law enforcement, air medical services, and hazardous materials (Hazmat) teams, just to name a few (Box 16-1).

CRITICAL THINKING

What type of information might you obtain during dispatch that would make you concerned that a hazardous materials incident exists?

SCENE SAFETY

There are many factors that can affect scene safety in an emergency response. Examples include environmental hazards, the presence of hazardous substances, violence, and rescue-related hazards (Box 16-2) (see Part 11: EMS Operations).

Environmental Hazards

Dealing with the environment is a unique aspect of prehospital care (see Chapter 45). Hot weather conditions can expose the patient to thermal injury. An example is thermal burns from placing a patient on a spine board that is left uncovered on hot asphalt. Likewise, heat-related illness (hyperthermia) can quickly escalate if the EMS crew does not take immediate measures to remove the patient from the hot environment. All patients who are at risk for hyperthermia should be moved to a cooler environment to begin care.

Cold weather poses many challenges as well. An ill or injured patient is less able to regulate body temperature, allowing hypothermia to develop quickly. Patients who are at risk for hypothermia should be immediately sheltered from the wind and moved to a warm environment. Wet clothing should be quickly removed and the patient should be covered with warm, dry blankets. Warming measures may need to be initiated.

BOX 16-2 Possible Hazards at an Emergency Scene

Environmental hazards
- Inclement weather
- Extremes in temperatures
- Slick or icy conditions
- Poor or inadequate lighting

Hazardous substances
- Chemical
- Biological
- Nuclear
- Explosive

Violence
- Patient
- Bystanders
- Animals
- Crime scenes

Rescue-related hazards
- Extrication
- Road operation dangers
- Specialized rescue situations

Caring for patients in a thunderstorm can be dangerous to everyone on the scene. Patients should be quickly moved to a location that is protected from lightning and other storm hazards. The paramedic should assume that wires downed from high winds are charged and dangerous until trained personnel verify their safety.

Many environmental hazards will warrant specialized rescue teams and additional resources. An example is rescue of a patient in water or on ice. Low light conditions can make patient assessment difficult and can easily contribute to personal injury. Portable light should be available to properly assess for hazards. Large rescue scenes should be properly lighted by requesting additional resources.

Hazardous Substances

Chemical, biological, radiological, and explosive hazards may be encountered from industrial accidents or terrorist incidents. Paramedics should be alert to dispatch information that indicates the potential for any of these hazards. Reports of large numbers of patients with similar signs or symptoms should signal the potential for one of these incidents. Assessment of a scene with a possible hazardous materials spill should be carefully planned. Scene assessment should begin at a distance using binoculars to look for the presence of indicators of hazardous materials. Indicators include container shape, smoke or vapor clouds, and identifying Hazmat placards. These scenes should not be entered until they have been secured and made safe by specialized teams, which may include law enforcement personnel, hazardous materials teams, or public health specialists. Specific information related to this type of response will be presented in Chapters 57 and 58.

FIGURE 16-1 Patient with a concealed weapon.

Violence

Many factors can contribute to a violent scene. An example is verbal aggression toward the EMS crew out of concern for the safety and well-being of a loved one. Drugs or behavioral illness can also alter a patient's behavior and create a dangerous situation. When patients or others on the scene display aggressive or violent behavior, the EMS crew should retreat from the scene until it has been secured by law enforcement personnel.

Paramedics should be alert for the presence of weapons at any scene. Traditional weapons include knives or guns. Other objects within reach of the patient also can be used as a weapon. Examples include tools, kitchen appliances, and household chemicals. In some states, concealed weapons are legal. All patients should be asked if they are carrying a knife, gun, or other weapon. If so, safely removing and securing the weapon during transport should be dictated by department policy (Figure 16-1).

Dogs or other pets can be a hazard to rescuers, particularly if they perceive their owner may be harmed. If dangerous animals are unsecured, the patient or a family member should be asked to contain them. If that is not possible, local animal control specialists should be summoned (Figure 16-2).

When responding to a known violent crime scene, the EMS crew should remain at a safe distance. This staging position should be maintained until law enforcement personnel have secured the area. Many crime scenes are not completely safe, even when law enforcement personnel are present. The paramedic should stay alert for clues that a dangerous situation can ensue or escalate.

NOTE
Paramedics should always keep in mind that a scene that appears safe can quickly become unsafe. All public service agencies play an important role in ensuring the safety of emergency response personnel.

FIGURE 16-2 Paramedics preparing to enter a home with a large dog.

FIGURE 16-3 Extrication in progress.

Rescue-Related Hazards

Scenes involving rescue can be very dangerous. Common motor vehicle collisions often involve patient extrication, sharp metal, broken glass, unstable vehicles, and leaking fluids that increase the risk of fire. If it is safe to approach a vehicle involved in a collision, the paramedic should put the patient's vehicle in park and turn off the ignition before beginning patient care. The extrication itself may create additional hazards related to the powerful cutting and spreading tools; a shifting vehicle; or the possibility that an air bag will violently deploy (see Chapter 55). Paramedics should not remain in the vehicle during extrication unless properly trained and wearing appropriate protective equipment (Figure 16-3).

Each time a paramedic enters a roadway to provide care, there is a risk of being struck by oncoming traffic. Measures to reduce this risk should be taken on all roadway calls, regardless of the roadway speed limit. The ambulance

should be positioned in a safe location. Other emergency vehicles and response personnel should park their units in a manner that shields the ambulance and the affected vehicles from oncoming traffic. Appropriate ANSI Class II vests (traffic vests) and other protective gear should be worn as outlined in departmental policies. A safety officer should monitor the scene at all times. Egress from the roadway should be made as quickly as possible. Safe roadway operations will be further addressed in Chapter 53.

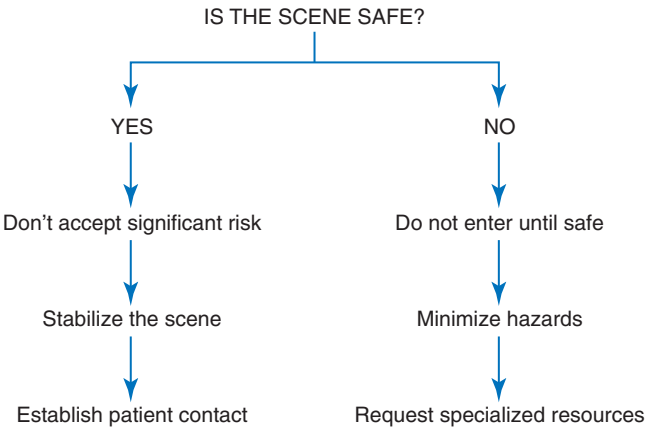

FIGURE 16-4 Scene safety algorithm.

FIGURE 16-5 Water rescue.

Specialized rescues require advanced training and equipment. Examples include scenes that involve high- and low-angle rescue, trench rescue, confined space rescue, water rescue, and unstable structure rescue. Each specialized rescue event can pose a variety of hazards. Paramedics should not assist with the rescue or enter the scene until it has been made safe for entry (Figure 16-4) (see Chapter 55).

EVALUATION OF THE SCENE

When evaluating the scene, the paramedic must always ask *"Is the scene safe?"* If the scene is not safe and cannot be made safe, the scene should not be entered. Rather, the EMS crew should remain in a **safe holding area** and request additional resources. Only when the scene has been secured should the area be entered by EMS personnel. If no safety hazards exist, the paramedic should establish patient contact and proceed with patient assessment (Figure 16-5).

Sometimes it may be possible to quickly make a scene safe to enter. For example, if the incident is on a busy roadway, emergency vehicles can be quickly positioned to provide protection for emergency personnel. Another way to make a scene safer to enter is to wear reflective vests and clothing to improve rescuer visibility (Figure 16-6). However, it must be stressed that making a scene safe to enter should only be considered when it can be done without accepting significant risk to the paramedic or the patient.

SCENE MANAGEMENT

Successful management of an emergency scene requires many considerations. Specific considerations to be discussed in this chapter include:

- Impact of the environment on patient care
- Addressing scene hazards
- Violent scenes
- Need for additional/specialized resources
- Standard precautions
- Multiple patient situations

FIGURE 16-6 Reflective ANSI Class 2 vests.

SHOW ME THE EVIDENCE

These authors attempted to quantify the incidence and types of violence EMS personnel encounter. This research was conducted in a county-wide fire department ALS EMS service that ran 40,000 calls per year. Medical students rode along on 342 EMS calls and made direct observations using a rating scale that measured verbally and physically aggressive behaviors. Of the 297 runs that met their inclusion criteria, they found 16 violent runs (5%, 95% CI 3% to 9%). The incidence of violence was not linked to day or week, time of day, or inner city versus other area runs. The patient was not the violent person in nearly one third of the cases.

Mock EF, Wrenn KD, Wright SW, et al: Prospective field study of violence in emergency medical services calls, *Ann Emerg Med* 32(1):33-36, 1998.

Impact of the Environment on Patient Care

A quick, visual survey of the scene should be made on all emergency calls. For medical calls, the paramedic should first determine the **nature of the illness.** This includes being observant of the patient's surroundings for possible clues to the nature of the emergency. For example, are there empty pill bottles or drug paraphernalia nearby? Is the patient wearing a medical alert necklace or bracelet? Are there any unusual odors? Are there any hazards at the scene that could suddenly make the scene unsafe?

For trauma calls, it is important to quickly determine the **mechanism of injury** (see Chapter 37). Visual clues can be significant in directing patient care and in anticipating patient care that may be needed while at the scene and during transport. For example, was a steering wheel, dashboard, or windshield damaged in a motor vehicle collision? Were the occupants in the car wearing personal restraints? Was the patient wearing a helmet when she crashed her motorcycle? What is the length of the knife that was used to stab the victim? Are there any hazards at the scene that could suddenly make the scene unsafe?

CASE STUDY 1

You respond to a residence for an "accidental injury." When you arrive you find a tearful pregnant woman and her boyfriend. She is quiet and appears fearful. Her boyfriend says she fell down the stairs. You note bruising around her abdomen and other injuries not consistent with that story.

CRITICAL THINKING

Case Study 1. How can you make this scene safer for both you and your patient?

Addressing Hazards

As stated previously, all emergency scenes should be assessed for any environmental conditions or hazards. To ensure scene safety, any hazard must be addressed. Environmental conditions and hazards that could affect patient care or the safety of patients, bystanders, or emergency personnel include:

- Weather or extreme temperatures
- Toxins and gases
- Secondary collapses and falls
- Unstable conditions

After making the scene safe for the paramedic, the safety of the patient becomes the next priority. The paramedic should attempt to correct any hazards that might threaten the health or safety of the patient. If a hazard cannot be alleviated, the patient should be moved to a safer environment. Likewise, any condition that poses a threat to bystanders should be minimized. They too should be moved to a safer area.

CASE STUDY 2

You are dispatched for multiple patients with headache and vomiting at a residence. The power is out because of severe storms. When you arrive on the scene you hear the sound of a generator running in the house.

CRITICAL THINKING

Case Study 2. What actions can you take as you arrive on the scene to treat these patients in a manner that is safe for both you and your patients?

Additional and specialized resources may be needed to address hazards at the scene. These resources should be requested as soon as possible. The need for additional resources should be anticipated quickly when the scene is initially scanned for mechanism of injury or nature of illness. For example, if there are multiple patients, additional ambulances will be needed. Fire service will be needed if there are fire or electrical hazards, chemical spills, biological threats, unsafe structures, and rescue or extrication requirements. Utility services may be required to manage downed power lines or to secure natural gas lines. Law enforcement personnel may be needed to control traffic, to manage bystanders, and to contain any violence at the scene (see Chapter 55).

NOTE

Paramedics should never enter a scene or approach a patient if the threat of violence exists. The EMS crew should retreat from the scene and remain in a safe area until the scene has been secured by law enforcement personnel. *If the scene is not safe and cannot be made safe, do not enter.*

Standard Precautions

As described in Chapter 14, the use of standard precautions should be part of any EMS response. To review, standard precautions are based on the principle that all blood, body fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes may contain transmissible infectious agents.

LOOK AGAIN

See Chapter 14: Venous Access and Medication Administration, pp. 380-381.

Standard precautions include a group of infection prevention strategies. These strategies apply to all patients, regardless of suspected or confirmed infection status. They also apply to any health care delivery setting where patient care activities take place. The extent of precautions used is determined by the anticipated likelihood of exposure to blood, body fluids, or pathogens. Standard precautions are implemented by thorough hand washing and by wearing:

- Gloves
- Protective eyewear
- Masks
- Gowns

NOTE

Universal precautions is the practice of avoiding contact with a patient's body fluids by wearing personal protective equipment. These precautions were developed for protection of health care personnel. *Standard precautions* combine major features of universal precautions and body substance isolation. These precautions focus on the protection of patients.

CASE STUDY 3

You are dispatched for a woman with abdominal pain. As you enter the patient's bedroom, you note that she is squatting and screaming "the baby is coming, the baby is coming!"

CRITICAL THINKING

Case Study 3. How can you minimize your risk of exposure to blood or bloody body fluids on this call?

PERSONAL PROTECTIVE EQUIPMENT

Personal protective equipment (PPE) includes any clothing or specialized equipment that provides some protection to the wearer (Figure 16-7). PPE protects the paramedic and other emergency personnel from substances that may pose a health or safety risk. PPE should be appropriate for the potential hazard. (PPE will be further addressed in Part 11: EMS Operations.) Examples of PPE include:

- Steel-toe boots
- Helmets
- Turnout gear
- Heat-resistant outerwear
- Reflective clothing
- Bullet-proof vests in high crime areas
- Safety glasses
- Hearing protection
- Self-contained breathing apparatus (SCBA)
- Leather gloves

Multiple Patient Situations

When responding to an incident where there are multiple patients, the paramedic should anticipate the need for additional support. Often times, the dispatch center has made this determination and requested assistance before EMS arrives at the scene. As stated earlier in this chapter, additional and specialized resources that may be needed are based on the nature of the incident. These may include additional ambulances and/or air medical service, additional manpower to sort and care for the injured, additional medical supplies, special equipment for extrication and fire suppression, specialized rescue teams, utility services, Hazmat decontamination, and traffic and crowd control, to name a few.

The goals of managing an event with multiple patients are to ensure scene safety, protect the patients, and protect the bystanders. Bystanders will need to be removed from the patient care area and isolated from the scene. Barricades may sometimes need to be erected and manned by law enforcement personnel to ensure the goals of managing the event. Large-scale scenes or major incidents will likely require a command structure to safely manage the scene. These command structures are known as *Incident Command System* (ICS) or *Incident Management System* (IMS). These systems organize interagency functions and responsibilities of emergency personnel and public service agencies at the

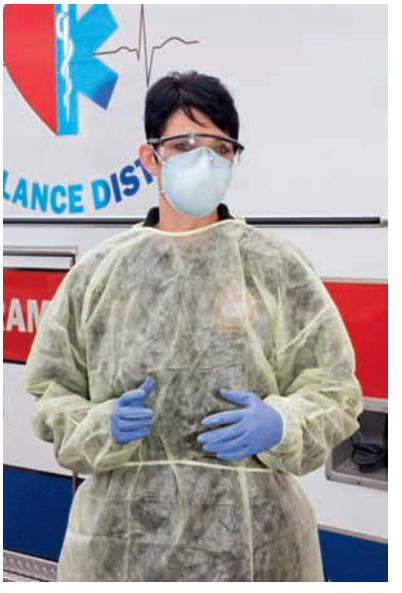

FIGURE 16-7 Example of personal protective equipment (PPE).

scene. Command structures play a vital role in scene management whenever available resources are insufficient to manage the number of casualties or the type of emergency. (Command systems will be described in detail in Chapter 54.) Examples of major incidents are listed below and in Box 16-2.

- Highway crashes
- Air crashes
- Major fires
- Train derailments
- Building collapse
- Acts of violence or terrorism
- Search and rescue operations
- Hazardous materials releases
- Natural disasters

CASE STUDY 4

Your unit is first to arrive at the scene of the call dispatched as a "motor vehicle collision." You find a school bus that left the roadway and rolled. You see multiple injured children. There is major damage to the bus and smoke is rising from the engine compartment. As you begin triage, your partner calls dispatch to establish command, to provide a brief size-up of the situation, and to request fire, rescue, and additional ambulances. Several parents in their cars have arrived at the scene.

CRITICAL THINKING

Case Study 4. What challenges will you face in managing this scene?

SUMMARY

- Scene size-up is a quick assessment of an emergency scene. It is designed to determine resources needed to manage the scene safely and effectively.
- Dispatch information that assists with scene size-up includes location, type of location, type of situation, possible hazards, and unique issues.
- Special rescue, transport, fire, or other public safety resources may need to be dispatched to help manage the scene.
- Many factors can contribute to an unsafe scene. These may include environmental hazards, hazardous substances, violence, and rescue-related hazards.
- Scene assessment should always begin by asking, "Is the scene safe?" If it is not, identify measures that eliminate or reduce the risk to permit safe entry.
- Perform an initial scene survey. On medical calls attempt to determine the nature of the illness. On trauma calls gather information related to the mechanism of injury.
- If hazards cannot be corrected, remove the patient from the scene as quickly as safely possible.
- Standard precautions should be used for all patients to minimize the risk of exposure to blood or bloody body fluids.
- Other specialized personal protective equipment may be needed based on the nature of the hazard and the training and role of the paramedic on the scene.
- Multiple patient situations require many resources. Priorities should always be scene safety with protection of the patient and bystanders. Incident command should be established.

CHAPTER

17 Therapeutic Communications

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Define therapeutic communications.
2. List the elements of effective therapeutic communications.
3. Identify internal factors that influence effective communications.
4. Identify external factors that influence effective communications.
5. Explain the elements of an effective patient interview.
6. Summarize strategies for gathering appropriate patient information.
7. Discuss methods of assessing the individual's mental status during the patient interview.
8. Describe ways the paramedic can improve communication with a variety of patients. Such patients include (1) those who are unmotivated to talk; (2) hostile patients; (3) children; (4) older adults; (5) hearing-impaired patients; (6) blind patients; (7) patients under the influence of drugs or alcohol; (8) sexually aggressive patients; and (9) patients whose cultural traditions are different from those of the paramedic.
9. Describe methods to communicate in a culturally sensitive manner.

KEY TERMS

closed-ended questions Questions that are restrictive in form and can be answered with a "yes" or "no."

cultural imposition Forcing one's beliefs, values, and patterns of behavior on people from another culture.

decoding The act of interpreting symbols and format.

empathy The ability to see a situation from the viewpoint of the person experiencing it.

encoding The act of placing a message in an understandable format (either written or verbal).

ethnocentrism Seeing one's own life as the most acceptable or best; acting in a superior manner toward another culture's way of life.

open-ended questions Questions asked in a narrative form that cannot be answered with a "yes" or "no."

private space A comfortable distance from the patient's body; usually about 4 to 5 feet or twice the patient's arm length away (also known as *personal space*).

sympathy The expression of one's feelings about another person's problem.

therapeutic communications A planned, deliberate, professional act that involves the use of communication techniques to achieve two purposes: (1) a positive relationship with the patient and (2) a shared understanding of information between the patient and the paramedic. These two factors aid in the attainment of the desired patient care goals.

***Therapeutic communications** can have several important effects. It can improve the paramedic's interaction with the patient, ensure better patient care, defuse potentially violent situations or prevent them from escalating, and reduce the risk of lawsuits.*

COMMUNICATION

Communication is the basic element of human interaction. It involves both verbal and nonverbal behavior. Moreover, it includes all the symbols and clues people use to convey

(Courtesy Ray Kemp. St. Charles, Mo.)

and receive meaning.[1] The process of communication has several elements. The paramedic must be aware of each element to interact effectively with a patient. Each element is crucial, and information and meaning can be gained or lost if any one element is changed (Figure 17-1). To achieve good communication, all participants must take equal responsibility for their part in the process. Communication is successful only when each person clearly understands the message.

NOTE
This chapter deals with communication between paramedics and their patients. However, these suggestions and techniques also can be used to improve communication between crew members, nurses, physicians, dispatchers, and other emergency personnel.

Elements of the Communication Process

Communication is a dynamic process. It has six elements: the source, encoding, the message, decoding, the receiver, and feedback.

SOURCE

Verbal communication uses spoken or written words (common symbols) to express ideas or feelings. (This is the *source* of the communication.) These common symbols should be simple, short, and direct to avoid confusion. Box 17-1 lists methods that can be used to achieve clarity in verbal communications.

CRITICAL THINKING
Think about the last time you had a misunderstanding with someone. Would any of the techniques listed in Box 17-1 have improved the situation?

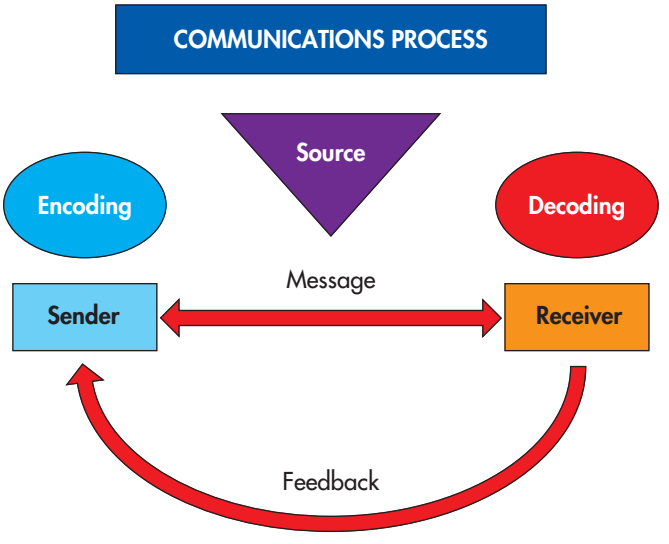

FIGURE 17-1 The process of communication.

ENCODING

Encoding is the act of placing a message in a format that, when translated, is understood by both the sender and the receiver. The format may be either written or verbal. Encoding is the responsibility of the sender (*encoder*), because the sender defines the content and emotional tone of the message. In the process of communication, the sender role may pass from one person to another as information is exchanged. For example, the paramedic may initially be the sender of the message by asking a patient for information. When the patient responds, that person assumes the role of the sender.

MESSAGE

The *message* is the information that is sent or expressed by the sender. It should be clear and organized. It should be communicated in a manner familiar to the person receiving it. The message may include verbal and nonverbal symbols (e.g., spoken words, facial expressions, gestures). As a rule, the more ways (or formats) in which a message is communicated, the more likely the receiver is to understand it. For example, combining soothing words and a reassuring touch for a patient in pain communicates the message of compassion better than spoken words alone.

Not all symbols have universal meaning. For example, a reassuring touch might be welcome to persons of certain cultures, whereas those of other cultures may find it offensive. Paramedics must take into account the cultural differences of people in their service area. They should also consider how they will deal with a language barrier before attempting to send a message.

NOTE
It is estimated that at least 17.9% of the U.S. population (47 million people) speak a language other than English at home.[2]

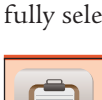
DECODING

Decoding is the interpretation of symbols and formats. It prompts the receiver to respond to the sender's message. The decoding process can fail if symbols or words sent in

BOX 17-1 Techniques for Verbal Communication

- Use fewer words to avoid confusion.
- Use words that express an idea simply.
- Do not use vague phrases.
- Use examples (including demonstrations) if they will make the message easier to understand.
- Repeat the important parts of a message.
- Do not use technical jargon.
- Speak at an appropriate speed or pace.
- Do not pause for long periods or quickly change the subject.

the message are unfamiliar to both parties. It also can fail if interpretation of the message is based on different understandings of symbols or format. For example, the word *pain* may mean horrific discomfort to one person. However, it may mean a mild annoyance to another. Therefore, when communicating with a patient, the paramedic must carefully select words that cannot easily be misinterpreted.

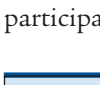


NOTE

Some medical conditions, such as a stroke, can make it more difficult for a person to encode or decode a message.

RECEIVER

The receiver is essentially the *decoder*. This is the person intended to understand the message. As with the role of sender, the role of receiver switches back and forth between participants during the communication process.



CRITICAL THINKING

Have you ever attended a class in which nothing made sense? Contemplate the reason you did not understand the content. Was it an encoding problem or a decoding problem?

FEEDBACK

Feedback is the receiver's response to the sender's message. The quality of the feedback reveals whether the intended meaning of the message was received. If the intended meaning was not received, the sender must clarify the message by modifying its content and reassessing the new feedback. Like the message, feedback may be verbal or nonverbal.

INTERNAL FACTORS IN EFFECTIVE COMMUNICATION

To communicate well with patients, paramedics must genuinely like people. They must be able to empathize with others. They also must have the ability to listen (Box 17-2). Each of these internal factors plays an important role in therapeutic communications.

Liking Others

As a "helping profession," health care depends on the relationships forged between patients and health care personnel. These relationships are based on trust and caring. In fact, they cannot be achieved without a genuine concern for others and an understanding of human strengths and weaknesses. Patients must trust and believe that a paramedic *wants* to care for their needs. Paramedics can convey this trust to patients by accepting them as individuals.

Empathy

Empathy is the ability to see a situation from the viewpoint of the person experiencing it. It is widely accepted as a clinical aspect of a helping profession. **Sympathy,** on the other hand, is the expression of one's feelings about another person's problem. Unlike sympathy, empathy uses sensitive and objective communication. This helps patients explain and explore their feelings so that problem solving can occur (Box 17-3).

BOX 17-2 Active Listening Attitudes and Guidelines

1. Listen to understand, not to ready yourself to reply, contradict, or argue back. This attitude is extremely important.
2. Remember that *understanding* involves more than simply knowing the dictionary meaning of the words used. It involves paying attention to the patient's tone of voice, facial expressions, and overall behavior.
3. Look for clues to what the individual is trying to say. As best you can, put yourself in the patient's shoes. Try to see the world as the patient sees it. Accept the patient's feelings as facts that must be taken into account, whether you share them or not.
4. Put aside your own views and opinions for the time being. Realize that you cannot listen to yourself inwardly and at the same time truly listen to the patient.
5. Control your impatience. Listening is faster than talking. The average person speaks about 120 words a minute. People can listen to about 400 words a minute. Do not jump ahead of the patient. Give the person time to tell the story. A patient does not always say what the paramedic expects to hear.
6. Do not prepare an answer while you listen. Get the whole message before deciding what to say. The patient's last sentence may put a whole new slant on what was said before.
7. Show the patient that you are alert and interested. This encourages the patient and improves communication.
8. Do not interrupt. Ask questions only to obtain more information. Do not try to trap the patient or force the individual into a corner.
9. Expect the patient's use of words to differ from yours. Do not quibble about terms—try to determine what was meant.
10. Your purpose is the opposite of a debater's goal. Look for areas of agreement, not for weak spots to attack with a barrage of counterarguments.
11. Before giving an answer in a particularly difficult discussion, summarize what you understand the patient to have said. If the patient disagrees with this version, clear up the contested points before giving your own views.
12. Let patients describe themselves and their interests, position, and opinions.

Ability to Listen

Listening is an active process. It requires complete attention and practice. To be an effective listener, the paramedic should[3]:

BOX 17-3 Empathy versus Sympathy

The case below shows the difference between empathy and sympathy. It also shows how empathy can help the paramedic soothe the patient and gain his trust.

Your emergency medical services (EMS) crew is sent to the home of a 60-year-old man with substernal chest pain. When you arrive, the patient is sitting on the living room sofa with his wife. They are upset and afraid that he might die. Your crew begins standard procedures for a possible heart attack and prepares to transport the patient to the emergency department. On the way to the hospital, the paramedic and the patient, who is accompanied by his wife, have the following conversation:

Paramedic: Even though you're feeling better, I can tell you're worried and afraid.

Patient: Yes, I am. I'm afraid I'm going to die.

Paramedic: Would you like me to explain to you and your wife what will happen after we arrive in the emergency department? I can also explain what the doctors and nurses will do to make sure you get the best possible care.

Patient: Yes, we would like that very much.

The use of empathy, shown in this conversation, allows the paramedic to accomplish three things: (1) calm the patient and his wife; (2) provide the couple with useful information; and (3) partly address their concerns. If the paramedic had used sympathy alone (e.g., "I understand how you feel, but don't worry, everything will be okay"), the patient's fears would have been ignored. Also, the problem of the couple's agitation would not have been solved.

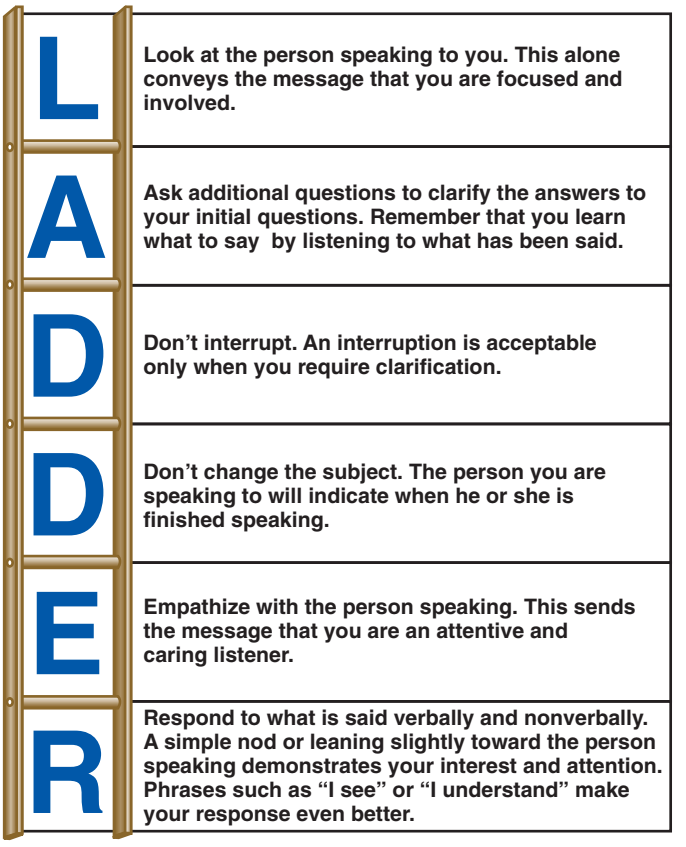

FIGURE 17-2 The ladder of listening.

1. Face patients while speaking.
2. Maintain natural eye contact to show a willingness to listen.
3. Assume an attentive posture (avoid crossing the legs and arms, because this may convey a defensive attitude).
4. Avoid distracting body movements (e.g., wringing the hands, tapping the feet, or fidgeting with an object).
5. Nod in acknowledgment when patients talk about important points or look for feedback.
6. Lean toward the speaker to communicate involvement.

One device for remembering ways to improve communication is the listening ladder (Figure 17-2). This device has six steps to listening. They can easily be remembered from the acronym LADDER.[4]

EXTERNAL FACTORS IN EFFECTIVE COMMUNICATION

Effective communication requires a suitable setting. The paramedic has control over a number of the external factors that affect the setting. Some of these are privacy, interruptions, eye contact, and personal dress. Control of these factors results in a better interaction between the paramedic and the patient.

Privacy, Interruptions, and the Physical Environment

When possible, the paramedic should ensure privacy during the encounter. This helps to eliminate distractions and to reduce any inhibitions the patient may feel. Interruptions should be kept to a minimum. When possible, the lighting should be adequate. Noise and interference should be minimized. In addition, the patient interview should be initiated away from distracting equipment.

The paramedic should be aware of the patient's **private space.** This is a comfortable distance from the patient's body. It is about 4 to 5 feet[5] or twice the patient's arm length away. Private space (also known as *personal space*) is a form of subconscious personal protection that varies by individual and by culture. Some patients may become defensive if this space is invaded. Entering this space usually causes the patient to back away.

Eye Contact

The paramedic should maintain eye contact with the patient as much as possible, even when taking notes. Eye contact is a type of nonverbal communication. It can help express gentleness, sincerity, and authority and can help make the patient feel safe and secure. If possible, the paramedic should be positioned at eye level (equal seating) with the patient.

NOTE
Most patients are comfortable with note taking. They understand it may be difficult for the paramedic to remember all details. If concerns arise, the paramedic should explain the purpose of taking notes as part of a thorough assessment.

Personal Dress

Communication with a patient begins with first impressions. Paramedics' appearance should be professional. Their clothing should be clean and should meet professional standards (e.g., uniforms provided by the EMS agency). These standards help the patient instantly identify the paramedic. They also help to set the tone of the paramedic-patient encounter.

PATIENT INTERVIEW

The ability to conduct a successful patient interview may be as important as physical assessment skills. The information gathered often helps to decide the direction of the physical examination. The patient interview should be initiated early and should continue throughout the patient encounter.

Because of the emergency nature of their work, paramedics often think in terms of specific illnesses and injuries. They often must categorize patients into general groups, such as trauma or medical cases. However, good emergency care requires the paramedic to view each patient as an individual. Moreover, it requires paramedics to attend to a patient's needs in a caring, concerned, and receptive manner.

Communication Techniques

The paramedic should approach the conscious patient and make a personal introduction by name and title: "Hello. My name is [name], and I am a paramedic with [name of EMS agency]. What's your name?" A verbal exchange with the patient will provide information about a person's level of consciousness and sensorium. It also may provide information on any hearing or speech impediments and language barriers. During the introduction, the paramedic should maintain eye contact with the patient.

Nonverbal communication can send a message of negative feelings. It also can convey the insecurities of both the patient and the paramedic. Voice inflection, facial expression, and body position are examples of these nonverbal cues. They may reflect anger, fear, or impatience. Similarly, performing patient care procedures with trembling, sweaty hands may make the patient question the paramedic's skills. Nonverbal cues should be used to gain the patient's trust and cooperation. These can help the paramedic provide the best care for the patient.

Touch is a form of communication. It shows compassion and reassurance. Small gestures can help comfort a person in distress. A few examples are holding a patient's hand, squeezing a shoulder, or wiping tears from a patient's eyes. Experience and familiarity with patient care activities help determine the appropriateness of these gestures.

In talking with patients, the paramedic must listen to what is said and interpret what is said. Patients may say they feel fine. Yet their appearance and tone of voice may indicate that they are ill and afraid. If paramedics are unsure of the message in a patient's response, they should ask additional questions that will help them better understand what the patient is trying to communicate.

Most patients do not understand medical terminology. In addition, many have only a vague understanding of the way their bodies work. For these reasons, common words and phrases that are easy to understand should be used. The paramedic should guide and direct the patient interview without manipulating the patient's response. In other words, the paramedic should avoid asking **leading questions** (questions that can be answered with only "Yes" or "No"). **Open-ended questions** encourage a free-form response. For example, the paramedic should ask, "When did this pain begin?" rather than "Did the pain begin this morning?"

DID YOU KNOW?
Open-Ended vs. Closed-Ended Questions
Open-ended questions are asked in a narrative form. They cannot be answered with a "yes" or "no." They encourage the patient to talk.

Closed-ended questions can be answered with a "yes" or "no." They are restrictive and may not provide much information.

Open-Ended Questions	Closed-Ended Questions
How can I help you?	Can I help you?
Where is the pain in your chest?	Do you have chest pain?
How are you feeling today?	Do you feel better today than yesterday?
When was your last meal?	Did you eat today?
What medicines do you take?	Do you take any medicines?
What examples can you give me?	Can you give me an example?
Where else do you hurt?	Is this the only place that hurts you?
Can you tell me how this happened?	Has this happened before?
Can you describe your pain?	Does your pain feel sharp?
What else would you like to ask me?	Does this answer your question?

NOTE
Open-ended questions:
Are asked in a narrative form.
Encourage the patient to talk.
Do not restrict the areas of response.

The paramedic should ask only one question at a time. The patient should be given ample time to answer the question before another question is asked. If the patient's response does not seem relevant to the question, the response should be clarified. Paramedics should be flexible. They should not discount the patient's experiences or information.

If possible, all questions asked by the patient should be answered. However, this does not mean that paramedics must provide a full explanation for each inquiry. Rather, a sensitive response that addresses the question is adequate. Paramedics should choose an answer carefully and should try to ensure the answer does not increase the patient's anxiety.

SHOW ME THE EVIDENCE

Researchers in Chicago evaluated characteristics of how physicians communicated with patients during the patient history and physical exam and during discharge instructions in 93 emergency department visits. Emergency medicine residents introduced themselves in only two thirds of cases and almost never (8%) indicated their training status. Sixty-three percent of the physicians began the history with an open-ended question; however, in only 20% of cases were patients permitted to complete their answer without interruption. Patients were interrupted in an average of 12 seconds. Discharge instructions lasted an average of 76 seconds and only 16% of patients were asked if they had questions. The researchers conclude that more provider education is needed.

Responses

There are many different tactics and responses that can be used to conduct a successful patient interview (Box 17-4). For example, the paramedic may use silence. This gives a patient more time to gather his or her thoughts. The paramedic also may *echo* (paraphrase) a patient's words. Echoing allows the paramedic to clarify or expand on the information provided. It also lets the patient know that the paramedic is listening. Empathy can be used to encourage a patient to talk more openly. Other tactics include asking a patient to clarify confusing statements and forcing the patient to focus on one factor of the interview (confrontation). At times the paramedic may need to interpret information by linking events, making associations, or inferring a cause based on what can be seen or concluded. Additional information (explanation) also can be given to a patient. This can persuade the person to share facts or objective information. Finally, paramedics can summarize information by asking the patient open-ended questions that can be used to review and to clarify important details.

Traps in Interviewing

Paramedics must be aware of some traps that can be damaging to the patient interview. These include the following:

BOX 17-4 Helpful Techniques for the Patient Interview

- Silence—Gives patients more time to gather their thoughts.
- Reflection—Echoing (i.e., paraphrasing) patients' words allows them to clarify or expand on the information provided.
- Empathy—Encourages patients to talk more openly.
- Clarification—Lets patients rephrase a word or thought that is confusing to the paramedic.
- Confrontation—Focuses patients' attention on one specific factor of the interview.
- Interpretation—Links events; makes associations or implies a cause; is based on observation or conclusion.
- Explanation—Provides information to patients; encourages sharing of facts or objective information.
- Summary—Provides a review of the interview; the paramedic can ask open-ended questions that allow patients to clarify details.

- Providing false reassurance
- Offering poor or unwanted advice
- Showing approval or disapproval
- Giving an opinion that takes away the patient's part in decision making
- Changing the subject inappropriately
- Stereotyping the patient or complaint
- Using professional jargon
- Talking too much
- Asking leading or biased questions
- Interrupting the patient
- Asking the patient "Why" questions (these can be viewed as accusations)
- Being defensive in response to criticism

Developing a Good Rapport With the Patient

Skill in developing good rapport with a patient requires experience and practice. In most patient encounters, paramedics can follow some general guidelines to help establish good rapport:

1. Put patients at ease by letting them know you are "on their side"; that is, that you respect their comments, and you are there to help them.
2. Be alert for and respond to visual clues that a patient needs help.
3. Show compassion.
4. Assess the patient's level of understanding and insight. Use words and explanations at their level.
5. Show expertise.

CRITICAL THINKING

A suicidal patient keeps telling you that you do not care about him. What communication techniques could you use to persuade this patient that you are concerned about him?

STRATEGIES FOR OBTAINING INFORMATION

Patients generally communicate with health care personnel in three ways. The first is by pouring out the information in the form of complaints. The second is by revealing some problems while hiding others they think are embarrassing. The third is by hiding the most embarrassing parts of their problem from the paramedic (and personally denying the issue). The best way to obtain information from the patient is to use techniques for open-ended and closed (direct) questions. These techniques include resistance, shifting focus, recognizing defense mechanisms, and distraction.

NOTE

Closed-ended questions allow the paramedic to obtain specific information that focuses on a certain aspect of the patient's condition. "What part of your back hurts?" and "When was your last meal?" are two examples of closed-ended questions.

Resistance

Often a patient is reluctant to give information for one of two reasons. First, the patient may want to maintain a personal image and is afraid of losing that image. Second, the patient may fear that the paramedic will respond with rejection and ridicule. Paramedics, therefore, should be nonjudgmental. This helps them to obtain information from patients (Box 17-5). To develop a trusting relationship, the paramedic must be willing to talk to the patient about *any* condition in a professional manner.

Shifting Focus

A patient may be hesitant to discuss an obvious problem. In this situation, the paramedic may have to shift the focus of the questions away from that problem. For example, a man with groin pain at first may describe the pain (especially to a female paramedic) as being in his "lower back." By shifting the focus of questioning to low back pain, the paramedic can use another group of questions that focus on the presence or absence of radiating pain. This new angle of questioning can make patients feel more comfortable when describing their condition.

BOX 17-5 Approaching Sensitive Issues

Discussing sensitive issues can be awkward for both the patient and the paramedic. Such issues might include alcohol use, sexual subjects, and suicide risk. Still, these issues must not be avoided when the information is needed to ensure good patient care. The paramedic should use the following guidelines when sensitive issues are discussed with patients:

- Make sure privacy is maintained.
- Be confident, direct, and firm with your questions.
- Do not apologize for asking a sensitive question.
- Do not be judgmental.
- Use words that are understandable, but do not be patronizing.
- Be patient and proceed slowly.

Defense Mechanisms

As described in Chapter 2: Well-Being of the Paramedic, paramedics should recognize common defense mechanisms. If possible, they should try to anticipate them. For example, a distraught parent with a seriously ill child may show regression or denial. The parent may be unable to provide needed information at the emergency scene. Confrontation may be required in these and similar situations to force the parent to deal with key issues. Confrontation can clarify roles. It also can help others identify problems and goals. However, this technique should be used only to obtain information critical for medical care. Confrontation must be performed in a professional way. This allows the patient to become aware of inconsistencies in interfering behavior or thoughts.

LOOK AGAIN

See Chapter 2: Well-Being of the Paramedic, pp. 42-44.

Distraction

Paramedics may use distraction to help patients recognize irrational thoughts or behavior. This type of behavior may be seen in hostile situations in which patients "act out." In such cases, paramedics need to point out the unacceptable behavior. They also need to let patients know the self-defeating nature of the behavior. Often, this distraction prompts patients to let the paramedic control the situation until they can gain self-control. When dealing with an angry or hostile patient, paramedics should:

- Avoid raising their voices to match the angry person's tone
- Have the person identify and describe the cause of anger
- Restate the cause of the anger
- Offer a solution (if possible) or empathize and acknowledge the person's feelings

METHODS OF ASSESSING MENTAL STATUS DURING THE INTERVIEW

Three methods can be used to assess a patient's mental status: observation, conversation, and exploration. (Assessment of the level of consciousness is discussed in more detail in other chapters.)

Observation

The first step in assessing mental status is to observe the patient. Paramedics should note the patient's appearance, level of consciousness, and normal or abnormal body movements. Physical characteristics, dress, and grooming can provide clues to the patient's well-being, social status,

religion, culture, and self-concept. Conscious patients generically are alert and able to speak intelligently. Body movements (e.g., gestures, facial expressions) should be appropriate for the situation. Abnormal body movements may indicate an unstable situation. Such movements may include unusual posture or gait, or clenched fists.

Conversation

Conversation with patients should reveal whether they know who they are, where they are, and the day or date (i.e., whether they are oriented to person, place, and time). If the patient knows these things, the remote, recent, and intermediate facets of memory probably are intact. The patient should be able to speak at a normal pace and with even flow. Responses should not have long pauses or rapid shifts. (However, such nuances vary by geographical location.) During normal conversation, the patient should be able to demonstrate clear thinking, a normal attention span, and the ability to concentrate on and understand the discussion.

NOTE

Evaluating a patient's orientation to person, place, and date (*oriented × 3*) also can include other parameters. Some health care professionals use time or event (e.g., most recent holiday) as a fourth component in the assessment (*oriented × 4*).

A patient's responses to the environment (*affect*) should be appropriate for the situation. Normal reactions to stress may include autonomic responses. Some of these are sweating and trembling and odd facial movements (e.g., muscle twitching around the mouth, nose, and eyes). Reactive movements, such as not holding eye contact during conversation, should be noted. Other actions may indicate that a patient is uncomfortable or anxious. These include grooming movements, such as fixing the hair and straightening the clothes.

Exploration

Exploration offers a way to assess the patient's emotions. For example, by observing that the patient's mood is anxious, excited, or depressed and by noting the individual's energy level, the paramedic can gauge the mental status. Exploration can be done simply by interacting with the patient. This allows the paramedic to observe the appropriateness of behaviors and ideas. An objective assessment must consider the patient's culture and educational background. It also must take into account the person's values, beliefs, and previous experiences.

Because time is often a consideration when providing emergency care, the following "basic" questions can be used during exploration with patients of various cultures.[6]

1. What do you think caused your problem?
2. Why do you think it started when it did?
3. What does your sickness do to you? How does it work?
4. How severe is your sickness? How long do you expect it to last?
5. What problems has your sickness caused you?
6. What do you fear about your sickness?
7. What kind of treatment do you think you should receive?
8. What are the most important results you hope to receive from this treatment?

CRITICAL THINKING

The mental status examination is critical, both for medical reasons and for legal reasons. Why do you think this is so?

SPECIAL INTERVIEW SITUATIONS

At times paramedics may have to use special skills to interact successfully with a patient who is uncooperative or frightened or who has a disability (also see Chapter 18: History Taking).

Patients Who Do Not Talk

Although most patients are more than willing to talk, some need more time and varying techniques to participate in a successful interview. Difficult interviews generally stem from four sources[5]:

1. The patient's condition may affect the ability to speak.
2. The patient may fear talking because of psychological disorders, cultural differences, or age.
3. The patient may have a cognitive impairment.
4. The patient may want to deceive the paramedic.

HELPFUL TECHNIQUES

The following techniques may be useful for communicating with a patient who is unmotivated to talk:

- Start the interview in the normal way. If the patient does not talk, review the nature of the call as received from the dispatch center. Take time to develop a rapport with the patient.
- Use open-ended questions to get a response. If this is unsuccessful, try direct questions.
- Provide positive feedback to appropriate responses from the patient.
- Make sure the patient understands the question. (Consider whether a language barrier or a hearing difficulty is a factor.)
- Continue asking questions to obtain critical information needed to provide treatment. (Nonessential information may be difficult to obtain.)
- Question family members or others at the scene. If the patient has been uncommunicative for a long period, try to rule out a disease or disorder as the reason.
- Use summary and interpretation of events or conditions. Also, ask the patient if your summary and interpretation are correct.

- Ask the patient questions about your care, equipment, or profession in an attempt to create conversation. If the patient responds, answer all questions fully (not with one-word answers).
- Realize that all the information needed may not be obtained.
- Observe the patient's affect and record what you see. This sets a mental status baseline for later evaluations.
- Consider asking questions for which answers are known. This helps to gauge the patient's credibility.

NOTE

Patients who are unconscious or unresponsive may be able to receive stimuli. Hearing is thought to be the last sensation lost with unconsciousness. It also is thought to be the first regained with consciousness.[4] The paramedic must not say anything near an unconscious patient that would not be said if the patient were fully conscious.

Hostile Patients

Paramedics should be alert for signs that a situation may turn violent. This is part of ensuring personal safety. Such signs may include clenched fists, a rising voice level, a threatening facial expression, or a history of violence toward others. If such a situation exists or is expected, the EMS crew should retreat from the scene and request the help of law enforcement officers. If safe retreat is not an option, the paramedics should stay far enough away from the patient to ensure their personal safety (see Chapter 35). Some guidelines that can be used in interviewing a hostile patient are:

- Try to use normal interviewing techniques.
- Never leave the patient alone without adequate assistance.
- Set limits and establish boundaries with the patient.
- Explain the advantages of cooperation to the patient.
- Follow local protocol for dealing with hostile patients, including the use of physical and chemical restraints.

Patients With Age-Related Factors

Communicating with children and older adults should not be difficult or a challenge. It works best when the paramedic takes into account the common developmental characteristics of a particular age group (see Chapter 12).

COMMUNICATING WITH CHILDREN

When communicating with children, the paramedic often must establish rapport with two people—the child and the parent. With children 1 to 6 years old, most conversation should be directed first to the parent. (Offering a toy may distract the child while the parent is interviewed.) The paramedic should be aware that information from the parent is that person's point of view, and the parent might be feeling defensive. Paramedics should not be judgmental if the parents had not provided proper care or safety for the child before EMS arrival. (Be observant but not confrontational.)

The paramedic should gradually begin to make contact with the child during the parent interview. This can be done by moving to eye level to speak with the child and by using a quiet, calm voice. It should be remembered that children are especially responsive to nonverbal cues. Box 17-6 lists special considerations for communicating with children of various ages. (Assessing pediatric patients will be further discussed in Chapter 48.)

COMMUNICATING WITH OLDER ADULTS

Many older adults are dealing with age-related diseases and the inevitability of death. Interviewing older adults may take longer than interviewing younger persons. Older patients may tire easily. They also may have physical disabilities that distort speech. Touch is generally important to most older adults. When interviewing an older person, the paramedic should always use the individual's last name and Mr., Mrs., or Ms. unless the patient requests otherwise. In addition, the patient should be able to see the paramedic's face easily. Eye contact should be maintained, and speech should be clear and slow. Additional time may be needed to gather patient information. Using short, open-ended questions and talking with family members usually are the best approaches for the patient interview. (Assessing the older adult will be further addressed in Chapter 49.)

Hearing-Impaired Patients

When dealing with a patient with a hearing impairment, the paramedic should determine the patient's preferred method of communicating. It may be lip-reading, signing, or writing. Writing often is the best out-of-hospital method for communicating with a deaf patient. If the patient prefers lip-reading, the paramedic should (1) face the patient squarely, (2) ensure lighting is adequate, (3) speak slowly using short words and phrases, and (4) enunciate clearly. Because many deaf patients lip-read, paramedics must speak clearly in full view of these patients. It is

BOX 17-6 Tips for Communicating With Children of Various Ages

- Infants respond best to firm, gentle handling and a quiet, calm voice. Older infants may have stranger anxiety. If possible, the parent should remain in view of the child.
- Preschoolers see the world only from their perspective and base everything on past experience. Use short sentences and give concrete explanations (e.g., "You will need to hold still so that I can splint your arm and make you feel better").
- Adolescents want to be adults. Treat them with respect and use age-appropriate words. Do not talk to or treat them as if they were small children.

important to note that some deaf patients may nod "Yes" even if they do not understand the question.

If a patient is thought to be hearing-impaired or deaf, the paramedic should try to gain the person's attention. This can be done by a gentle touch or by slowly waving the hands in front of the patient. The paramedic also may try speaking a little louder or speaking into the patient's ear if the person is not wearing a hearing aid. If a hearing-impaired patient needs to be transported to a medical facility, the paramedic should inform the emergency department staff as soon as possible about the impairment. This allows arrangements to be made for personnel to aid in communications with the patient. (This is also a good practice with patients who do not speak English.) Finger-spelling and simple sign language are easily learned and can assist the paramedic in communicating with deaf patients in the prehospital setting.

Blind Patients

When communicating with a blind patient, it should be ascertained whether the patient also has a hearing impairment. (However, it is unusual for sightless people also to be deaf.) Paramedics should identify themselves in a normal voice. All questions about the emergency scene and the surroundings should be answered. In addition, all examination and treatment procedures should be explained in detail before touching the patient.

Most patients who have disabilities are very independent. They may resent unsolicited help. If a sightless person has a guide dog and the situation permits, the two should not be separated. If the dog was injured during the emergency event, the dispatch center should be quickly advised. This will allow for special arrangements to be made to care for the dog.

Patients Under the Influence of Street Drugs or Alcohol

If street drugs or alcohol play a part in an emergency, paramedics should ensure their personal safety. They should also be prepared for unpredictable patient behavior. (The help of law enforcement officers may be needed to ensure scene safety.) During the patient interview, simple and direct questions should be asked. Any action that might be viewed by the patient as a threat or confrontation should be avoided (see Chapters 34 and 35).

Sexually Aggressive Patients

Paramedics should confront male or female patients who make improper sexual advances. This ensures that the patient is aware of the professional role of the paramedic. Unusual incidents and observations of witnesses to inappropriate actions should be documented. If possible, sexually aggressive patients should receive care from paramedics of the same gender. It also is best to have a chaperone or witness present during the care and transportation of the patient. Some EMS services use audio devices during transport to record all interactions with sexually aggressive patients. (The use of these devices may require the patient's legal consent.)

Transcultural Considerations

When speaking with a patient from another culture, paramedics should introduce themselves and then ask the patient to do the same. Paramedics must be aware that they may be viewed as a cultural stereotype to the patient and family. For this reason, the roles of everyone involved in providing care (paramedics, patient, and family members) must be clearly understood. Box 17-7 outlines pitfalls to avoid when caring for patients of other cultures.

Two pitfalls that paramedics must avoid when speaking with patients of a different culture are ethnocentrism and cultural imposition. **Ethnocentrism** is seeing one's own life as the most acceptable or best. It includes acting in a superior manner toward another culture's way of life. **Cultural imposition** is forcing one's beliefs, values, and patterns of behavior on people from another culture. Paramedics do not fall into these pitfalls on purpose. Yet they must be sensitive to how their actions and words may be seen by those of another culture. Other factors to consider in communicating with patients of another culture are:

- Some cultures expect health care workers to have all the answers to their illness.
- Different cultures accept illness or injury in different ways.

BOX 17-7 General Guidelines for Working With an Interpreter

As a paramedic, you sometimes will be asked to assist a patient who does not speak English. Often someone in the home or at the scene can help you communicate with the person. When working with an interpreter, use the following guidelines:

1. Explain to the interpreter the key information you are trying to get before you begin the interview.
2. Ask a child to interpret only if no adult interpreter is available.
3. Speak directly to the patient or to a family member when asking questions. This establishes the primary relationship with that individual (not the interpreter). It also allows you to observe nonverbal clues.
4. Ask questions that require one response at a time. For example, ask, "Do you have pain?" rather than "Do you have any pain, trouble breathing, or nausea?"
5. Try not to interrupt the patient, family member, or interpreter when that person is speaking.
6. Do not make comments about the patient or family to the interpreter; the patient or family may know some English.
7. Use simple language. Do not use medical terms for which other languages may have no similar words.
8. After the interview, if time permits, ask for the interpreter's impressions and observations of the interview.

Modified from Wong D: *Whaley and Wong's nursing care of infants and children,* ed 5, St Louis, 1995, Mosby.

- Nonverbal cues (e.g., handshaking and touching) are perceived differently in different cultures.
- Some cultures consider direct eye contact impolite or aggressive; patients may avert their eyes during an interview.
- Paramedics should not use touch as a means of reassurance with members of different cultural groups because touch may be easily misunderstood.
- Language barriers may present communication difficulties (Box 17-8).
- Personal space is often defined by culture. It also varies by individual (Box 17-9).

CRITICAL THINKING

Do you know anyone whose personal space requirements are much greater or much less than those listed in Box 17-9? How would this affect your interview with that person?

BOX 17-8 10 Tips for Improving the Caregiver-Patient Relationship Across Cultures

1. Do not treat the patient in the same manner you would want to be treated. Culture determines the roles for polite, caring behavior and will formulate the patient's concept of a satisfactory relationship.
2. Begin by being more formal with patients who were born in another culture. In most countries, a greater distance between caregiver and patient is maintained through the relationship. Except when treating children or very young adults, it is best to use the patient's last name when addressing him or her.
3. Do not be insulted if the patient fails to look you in the eye or ask questions about treatment. In many cultures, it is disrespectful to look directly at another person (especially one in authority) or to make someone "lose face" by asking him or her questions.
4. Do not make any assumptions about the patient's ideas about the ways to maintain health, the cause of illness, or the means to prevent or cure it. Adopt a line of questioning that will help determine some of the patient's central beliefs about health/illness/illness prevention.
5. Allow the patient to be open and honest. Do not discount beliefs that are not held by Western biomedicine. Often, patients are afraid to tell Western caregivers that they are visiting a folk healer or are taking an alternative medicine concurrently with Western treatment because in the past they have experienced ridicule.
6. Do not discount the possible effects of beliefs in the supernatural on the patient's health. If the patient believes that the illness has been caused by *embrujado* (bewitchment), the evil eye, or punishment, the patient is not likely to take any responsibility for his or her cure. Belief in the supernatural may result in his or her failure to either follow medical advice or comply with the treatment plan.
7. Inquire indirectly about the patient's belief in the supernatural or use of nontraditional cures. Say something like, "Many of my patients from ___ believe, do, or visit___. Do you?"
8. Try to ascertain the value of involving the entire family in the treatment. In many cultures, medical decisions are made by the immediate family or the extended family. If the family can be involved in the decision-making process and the treatment plan, there is a greater likelihood of gaining the patient's compliance with the course of treatment.
9. Be restrained in relating bad news or explaining in detail complications that may result from a particular course of treatment. "The need to know" is a unique American trait. In many cultures, placing oneself in the physician's hands represents an act of trust and a desire to transfer the responsibility for treatment to the physician. Watch for and respect signs that the patient has learned as much as he or she is able to handle.
10. Whenever possible, incorporate into the treatment plan the patient's folk medication and folk beliefs that are not specifically contradicted. This will encourage the patient to develop trust in the treatment and will help ensure that the treatment plan is followed.[7]

BOX 17-9 General Guidelines on Personal Space*

Intimate Zone
- 0 to 1½ feet
- Visual distortion occurs
- Best for assessing breath and other body odors

Personal Distance
- 1½ to 4 feet
- Perceived as an extension of self
- Speaker's voice is moderate
- Body odors are not apparent
- Much of the physical assessment occurs at this distance

Social Distance
- 4 to 12 feet
- Used for impersonal business transactions
- Perceptual information is much less detailed
- Much of the patient interview occurs at this distance

Public Distance
- 12 feet or farther
- Interaction with others is impersonal
- Speaker's voice must be projected
- Subtle facial expressions are imperceptible

*These are only general guidelines. Some cultures are more comfortable at a variety of distances when communicating.

SUMMARY

- Therapeutic communications is a planned act. It is also a professional act. The paramedic, working with the patient, obtains information that is used to meet patient care goals.
- Communication is a dynamic process. It has six elements: the source, encoding, the message, decoding, the receiver, and feedback.
- To effectively communicate with patients, paramedics must genuinely like people. They must be able to empathize with others. They also must have the ability to listen.
- Good communication requires a favorable physical environment. Factors such as privacy, interruption, eye contact, and personal dress are external influences. These factors can be controlled. This allows the paramedic to better communicate with the patient.
- The patient interview often decides the direction of the physical examination. Good care means that the paramedic sees each patient as an individual. It also means that the patient's needs are met in a caring, concerned, and receptive way.
- Open-ended and closed-ended (direct) questions can be used to get information from the patient. Techniques include resistance, shifting focus, recognizing defense mechanisms, and distraction.
- The first step with any patient is to assess mental status. This can be done by observing the patient's appearance and level of consciousness. The paramedic also can look for normal or abnormal body movements. During normal conversation, the patient should be able to show clear thinking, a normal attention span, and the ability to concentrate on and understand the discussion. The patient's responses to the environment (i.e., affect) should be appropriate to the situation.
- Difficult interviews generally arise from four situations: (1) the patient's condition may affect the ability to speak; (2) the patient may fear talking because of psychological disorders, cultural differences, or age; (3) a cognitive impairment may be present; or (4) the patient may want to deceive the paramedic.
- Paramedics should avoid ethnocentrism and cultural imposition when caring for patients from other cultures.

CHAPTER

18 History Taking

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Describe the purpose of effective history taking in prehospital patient care.
2. List components of the patient history as defined by the National EMS Education Standards.
3. Outline effective patient interviewing techniques to facilitate history taking.
4. Describe how the paramedic uses clinical reasoning.
5. Outline the process to determine differential diagnoses.
6. Identify strategies to manage special challenges in obtaining a patient history.

KEY TERMS

chief complaint A patient's primary complaint.

clinical reasoning Use of the results of questions to think about associated problems and body system changes related to the patient's complaint.

current health status A focus on the patient's current state of health, environmental conditions, and personal habits.

differential diagnosis The process of weighing the probability of one disease versus that of other diseases possibly accounting for a patient's illness.

family history Illness or disease in a patient's family or family's background that may be relevant to the patient complaint.

history taking Information gathered during the patient interview.

opening questions Questions that determine why the patient is seeking medical care or advice.

past medical history A patient's medical background that may offer insight into the patient's current problem.

present illness Identification of the chief complaint and a full, clear, chronological account of the symptoms.

History taking *refers to details that are gathered during an interview with a patient. History taking provides an account of medical and social events in a patient's life. The history also indicates environmental factors that may have an impact on the patient's condition. Obtaining a patient history gives structure to patient assessment. History taking often is crucial to establish priorities in patient care.*

(Courtesy Ray Kemp, St. Charles, Mo.)

COMPONENTS OF THE PATIENT HISTORY

The patient history that is obtained in the prehospital setting is focused on the patient's problem or the reason EMS was summoned (*a problem-based history*). It has several

purposes.[1] First, the patient history places emphasis on identifying life-threatening conditions that require immediate intervention. That is, it gives full attention to the "needs of the moment." The patient history provides information that leads to appropriate care for the patient who is *urgent* (unstable), *emergent* (potentially unstable), and *nonemergent* (stable). In addition, the patient history identifies the potential for life threats as well as the existence of a current life threat.

Finally, the patient history can be expanded when appropriate to allow opportunities for patient education. It can also allow opportunities to provide service referrals to agencies and organizations that can help the patient and/or family with specific health care needs.

LOOK AGAIN

See Chapter 3: Injury Prevention and Public Health, pp. 56-58.

CONTENT OF THE PATIENT HISTORY

The patient history is made up of several parts. Each of these parts has a specific purpose, which offers a "snapshot" of patients and their condition. Box 18-1 lists the parts of a patient history, as described in this chapter.

The patient history should include the date and time that the history was obtained. The history also should contain any identifying information of the patient (e.g., age, gender, race, and occupation). Identifying information can be key, as illustrated in the following scenario: Your crew has been dispatched to a "sick case." On your arrival you find a woman who is ill with flulike symptoms. The symptoms include nausea, vomiting, and diarrhea. During your interview, she tells you that she is a 49-year-old businesswoman. She has just returned to the United States from an extended visit to her native home in Southeast Asia. In addition to the chance of gastrointestinal illness or food poisoning, you now suspect that she could be ill from an endemic disease (that is, a disease prevalent in a population or geographical region).

Documentation should include the source of the referral and patient history. For example, did the patient request EMS assistance, or did a family member, friend, law enforcement officer, or bystander initiate the EMS response? The paramedic also must decide whether the source of the referral and patient history is reliable, as illustrated in the following scenario: Your crew has been dispatched to a car crash. The driver of the car is a 17-year-old who has minor injuries. He is slurring his speech. In addition, his breath smells of an odor resembling alcohol. He denies alcohol or other drug use to you and the law enforcement officers at the scene. Is this patient history reliable?

The chief complaint (explained later in this chapter) is the main part of the patient history. The chief complaint is the reason why EMS was summoned. After identifying the chief complaint, the paramedic obtains a history and description of the present illness or injury. This history provides a chronological account of the patient's symptoms. The paramedic then questions the patient about any past medical history and current health status. Also, the paramedic performs a review of body systems appropriate to the patient's symptoms or complaint (see Chapter 20).

BOX 18-1 Content of the Patient History

Date and Time

Identifying Data
- Age
- Gender
- Race
- Occupation

Source of Referral
- Patient referral
- Referral by others

Source of History
- Patient
- Family
- Friends
- Police
- Others

Reliability
- Variable (memory, trust, motivation)
- Determined at the end of the evaluation

Chief Complaint
- Main part of history
- The one or more symptoms for which the patient is seeking medical care

Present Illness
- Identifies the chief complaint
- Provides a chronological account of the patient's symptoms

Medical History

Current Health Status

Review of Body Systems

TECHNIQUES OF HISTORY TAKING

As described in Chapter 17, it is important to "set the stage" for a good paramedic-patient encounter. This is done by establishing a good first impression and by making the environment conducive to free-flowing communication. The paramedic should do the following:

- Establish a professional demeanor with the patient.
- Ensure patient comfort and provide a safe environment.
- Greet the patient by name or surname and avoid demeaning terms (e.g., "Granny," "Pop," or "Hon").
- Avoid entering the patient's personal space.

- Inquire about the patient's feelings.
- Be sensitive to the patient's feelings and experiences.
- Watch for signs of uneasiness.
- Use language that is appropriate and easily understood.
- Ask open-ended questions and direct questions (if needed).

LOOK AGAIN
See Chapter 17: Therapeutic Communications, pp. 483-485.

NOTE
Remember that your demeanor and appearance are very important in "setting the stage." Just as you are watching the patient, the patient will be watching you.

Opening questions are questions that determine why the patient is seeking medical care or advice. Opening questions may incorporate facilitation, reflection, clarification, empathetic responses, confrontation, interpretation, and asking patients about their feelings.

Facilitation: Use your posture and positive actions or words to encourage the patient to say more. Maintain eye contact and use phrases such as "go on" and "I'm listening." These phrases encourage the patient to continue talking.

Reflection: Repeat or "echo" what the patient tells you. This encourages additional responses. Reflection usually will not bias the patient's story or interrupt the patient's train of thought.

Clarification: Ask questions to better grasp vague statements or words.

Empathy: Ask about the patient's feelings and show empathy to interpret the patient's feelings. This will help to gain your patient's trust.

Confrontation: Some issues may necessitate confronting patients about their feelings. For example, one may ask a patient who is severely depressed, "Have you ever thought about killing yourself?"

Interpretation: When appropriate, go beyond confrontation and make an inference from the patient's response. For example, draw an inference from the patient who says, "I think I'm going to die." One may infer that the patient may be gravely ill.

Ask patients about their feelings: Use therapeutic techniques described in Chapter 17 to encourage patients to explain how they feel.

Chief Complaint

As previously stated, the **chief complaint** is the patient's primary complaint, and is usually the reason for the EMS response. The complaint may be verbal (e.g., complaint of chest pain) or nonverbal (e.g., pain or distress expressed by a facial grimace). Most chief complaints are characterized by pain, abnormal function, a change in the patient's normal state, or an unusual observation made by the patient (e.g., heart palpitations).

NOTE
When exploring the chief complaint, it is important to ask every patient:

"What do you think is wrong with you?"
"What are your specific concerns about your condition?"
"What do you think caused your problem?"

The patient's answers to these questions may be very relevant.

The paramedic should be aware that a chief complaint may be misleading. Also, a problem may be more serious than the complaint indicates. For example, the patient who has fallen down a flight of steps may complain of an injured ankle. However, physical examination may reveal possible internal injuries. Or, the patient may have fallen because of sudden paralysis on one side of the body related to a stroke. In addition, patients often modify or substitute their chief complaint. They may do this to hide a problem they find embarrassing or difficult to discuss. For example, a chief complaint of vaginal bleeding may be modified as "a heavy period." Actually, the bleeding was an abrupt hemorrhage that occurred during intercourse. Likewise, a chief complaint of "frequent headaches" may be substituted for feelings of depression with suicidal thoughts. Thus determining the *true* reason for the patient's concern is one of the skills of history taking. After identifying the patient's chief complaint (and managing any life-threatening situations), the paramedic should obtain a history of the present illness and any relevant medical history.

NOTE
Remember that the true needs of the patient may not be the stated chief complaint.

CRITICAL THINKING
What illnesses or injuries could cause a chief complaint of confusion?

History of Present Illness

The **present illness** identifies the chief complaint and provides a full, clear, and chronological account of the patient's symptoms. Obtaining a full history of the present illness takes skill. It takes skill in asking proper questions related to the chief complaint and in interpreting the patient's response. For example, a patient's complaint of low back pain suggests a muscle strain. During direct questioning in the interview, however, the patient reveals a history of a burning sensation with urination and a low-grade fever for the past several days. This information suggests a urinary tract infection or renal stones. Thus the history of the present illness may be more crucial than the obvious chief complaint. The mnemonic *OPQRST* helps define the patient's complaint by focusing on essential elements of

BOX 18-2 OPQRST Mnemonic

O (onset/origin): What were you doing when the pain started? Do you have a history of this problem?
P (provokes): What provokes the symptoms? What makes the symptoms better? What makes them worse?
Q (quality): What does the pain feel like? Is it sharp, dull, burning, or tearing?
R (region): Where is the symptom? Where does it go? Is it in one or more areas?
S (severity): On a scale of 1 to 10, with 1 being the least and 10 being the worst, what number would you give your pain or discomfort?
T (time): How long have you had this symptom? When did it start? When did it end? How long did it last?

BOX 18-3 SOCRATES Survey

S: Site
O: Onset (e.g., sudden, gradual)
C: Character (e.g., dull, sharp, stabbing)
R: Radiation
A: Associated symptoms (e.g., what else did you notice?)
T: Time, course, duration
E: Exacerbating and relieving factors
S: Severity (using a scale of 1 to 10)

assessment (Box 18-2). Use of this or another memory device (e.g., *SOCRATES* survey) will help lead the paramedic through a thorough series of questions to better understand the chief complaint (Box 18-3). The paramedic should take notes while obtaining the health history. Most patients realize that it is difficult to remember all details and accept note taking.

ONSET/ORIGIN

Onset and origin identify what the patient was doing when the pain began. The paramedic also notes whether there is any history of a similar episode. Questions to ask to obtain this information may include the following:

- "Did the pain or discomfort begin suddenly, or did it occur gradually over time?"
- "When did you last feel well?"
- "What were you doing when the pain started?"
- "Did the pain begin during a period of activity or while at rest?"
- "Have you ever had this type of pain or discomfort before? If so, is it the same or is it different than what you're experiencing now?"

PROVOKE/PALLIATION

Provoke and palliation refer to precipitating factors associated with the patient's complaints. Questions to ask to identify precipitating factors may include the following:

- "What makes your pain or discomfort better?"
- "What makes your pain or discomfort worse?"
- "Does the pain increase or decrease when you take a breath?"
- "Does lying down or sitting up affect your level of discomfort?"
- "Have you taken any medications for your symptoms? If so, did the medications make you feel better?"

QUALITY

Quality refers to how the patient perceives the pain or discomfort. Questions to ask to determine quality of the pain include the following:

- "What does the pain feel like?"
- "Can you describe the pain to me?"
- "Is the pain sharp or dull?"
- "Is the pain constant, or does it come and go?"

REGION/RADIATION

Region and radiation refer to the location of the pain and whether it is localized or associated with pain elsewhere in the body. Questions to ask to identify region and radiation include the following:

- "Where is the pain?"
- "Can you point with one finger to the exact location of the pain?"
- "Does the pain stay in the same place or does it move?"
- "If the pain moves, where does it go? Does the pain go to more than one area?"

SEVERITY

Severity refers to how the patient rates the level of the pain or discomfort. Severity also provides a baseline for future evaluation of the patient's pain. Questions to ask the patient include the following:

- "On a scale of 1 to 10, with 1 being the least and 10 being the worst, how would you rate your pain or discomfort?"
- "How bad is the pain?"
- "Does the intensity of the pain vary or does it stay the same?"
- "Have you had this type of pain before? If so, how is this pain different, or is it exactly the same?" (Figure 18-1)

SHOW ME THE EVIDENCE

These researchers performed a retrospective study of 1227 ambulance run sheets to evaluate the feasibility of using pain scales for measuring prehospital pain level and for determining the severity of pain in prehospital patients older than age 13. This was conducted after implementation of a pain assessment protocol. Pain was assessed in 84% of conscious patients using either a verbal rating scale (VRS) or a numerical rating scale (NRS). A total of 31% of patients in their sample reported moderate to severe pain. These findings confirmed that use of the VRS and NRS to assess pain was possible in the field.

McLean S, Domeier R, DeVore H, et al: The feasibility of pain assessment in the prehospital setting, *PEC* 8 (2):155-161, 2004.

FIGURE 18-1 **A,** Visual analog pain scale. **B,** Wong FACES pain rating scale. (From Wold GH: *Basic geriatric nursing,* ed 4, St Louis, 2008, Mosby.)

TIME

Time refers to the duration of the pain or discomfort. Questions to ask to clarify the duration of the patient's pain or discomfort include the following:

- "How long have you been feeling this way?"
- "Have you had this same type of pain before, and if so, how long did it last?"
- "When did the pain or discomfort start?"
- "How long did the pain or discomfort last?"
- "When did the pain or discomfort end?"

Past Medical History

An important element of history taking is obtaining the patient's **past medical history.** This step can occur after the paramedic gains a good grasp of the patient's chief

BOX 18-4 Elements of the SAMPLE Survey

S: Signs and symptoms
A: Allergies
M: Medications
P: Past medical history
L: Last meal or oral intake
E: Events before the emergency

BOX 18-5 Complex Medical Histories

Adult patients with complex medical histories should be asked if they have ever had:

- Asthma
- Diabetes
- Hypertension
- Jaundice
- Myocardial infarction
- Seizures
- Stroke
- Thromboembolism
- Tuberculosis
- Hospital admissions

Nonsensical memory tool: All Day Helps Jack Make Sticks & Stones To Take Home.

complaint. The past medical history may include, for example, diabetes, and cardiac or respiratory disorders. This history may add insight into the patient's current state. Important past medical history information may include the following:

- General state of health
- Medications
- Allergies and nature of allergic reactions
- Childhood illnesses
- Adult illnesses
- Psychiatric illnesses
- Previous injuries
- Physical disability attributable to previous illness or injury
- Surgeries
- Hospitalizations

A variety of memory devices are used to recall key questions for gathering medical history. One example is the *SAMPLE Survey* (Box 18-4). Regardless of the patient's past medical history, there are important, direct questions that should be asked of every patient (Box 18-5). The answers to these specific questions can be significant in the development of a field impression. Pertinent positives and pertinent negatives can help build a complete picture of the patient's medical history.

BOX 18-6 Personal Habits and Environmental Conditions

Personal Habits

Tobacco use
Alcohol, other drugs, and related substances
Diet
Screening tests
Immunizations
Sleep patterns
Exercise and leisure activities
Use of safety measures
Home situation, spouse, or significant other
Physical abuse or violence
Sexual history
Daily life
Important experiences
Religious beliefs
Patient outlook

Environmental Conditions

Home conditions: housing; cleanliness; temperature; economic condition; pets and their health
Occupation: description of past and present work; exposure to heat, cold, and industrial toxins; similar complaints of illness among co-workers
Travel: exposure to contagious diseases; residence in tropics; water and milk supply; and other possible sources of infection
Military record: geographical areas; exposure to chemicals

CURRENT HEALTH STATUS

A **current health status** focuses on a patient's current state of health. It also considers personal habits and environmental conditions (Box 18-6). Details regarding allergies, medications, last oral intake, and family history can be critical to the patient's current health status. Female patients with abdominal pain should be questioned about their last menstrual period (if of child-bearing age). All patients with abdominal pain should be asked about their last bowel movement. Finally, the paramedic should identify events that occurred before the emergency.

DID YOU KNOW?

Family History/Social History

A family history can give clues to possible predisposition to medical illness. It is known that certain diseases and health conditions tend to run in families. Examples include heart disease, cancer, hypertension, and stroke. Family history can also provide insight into why a patient may be anxious about contracting a particular disease. For example, a patient whose sister and aunt developed schizophrenia in their late twenties might be overly concerned that his son's irrational behavior is a sign of the same disease. When obtaining a medical history of family members or blood relatives, the paramedic should ask about family member health, ages, and causes of death for parents, siblings, spouse, and children.

A patient's social history can also be important. Questions should be focused on aspects of a patient's social history that may be affected by or connected to illness risk factors. Topics that may be appropriate to discuss include:

- Family (marriage, children)
- Dynamics in the home
- Dynamics in the workplace
- Financial circumstances
- Activities (work and leisure)

Other elements of a social history that may affect risk factors for illness include smoking, drinking, and drug use (past or present); sexual habits; current and previous occupation(s); and any recent travel abroad. Family pets and exposure to animals or birds can also be important and should be part of the patient's social history.

NOTE

Many persons have a life-threatening allergy to latex. Latex is a common substance found in emergency medical services care equipment.

MEDICATIONS

The paramedic should ask whether the patient takes any medications on a regular basis and, if so, for what reasons. In addition to information about prescribed medicines, information about the use of over-the-counter medicines is important. The paramedic also should ask about the use of herbs, naturopathic, and homeopathic medicines. This line of questioning should include the reason and frequency of use. If possible, the paramedic should determine whether the patient adheres to a medication regimen. The medication history may offer clues to the chief complaint. For example, a diabetic patient may have taken insulin but may have eaten at odd intervals. Other examples include a patient with chest pain who takes various cardiac drugs, an irrational patient who takes prescribed sedatives, and a trauma patient who takes blood-thinning drugs. In some cases it is helpful to examine the prescription fill date to determine whether the patient has been taking the medications as prescribed. Older adults with dementia may neglect to take medications or take them more often than prescribed.

CRITICAL THINKING

What would you do if you could not recognize the names or indications for the patient's home medicines?

The patient's medication history may not always be relevant to the problem at hand. However, the history can point to potential problems that may be seen during the patient care episode. There may be times when it is wise to directly ask a patient if he or she has taken specific drugs. For example, before giving ***nitroglycerin*** it is important to ask the patient if he has taken any drugs for erectile dysfunction such as Cialis, Levitra, or Viagra. Administration of ***nitroglycerin*** to patients who have recently taken these drugs can cause life-threatening hypotension.

NOTE

Patients should also be questioned about alcohol use and illicit drug use. A direct line of questions is best. For example, "Mr. Jones, it is policy to ask all patients these questions, so please don't be offended. Have you used alcohol today? Have you taken any tablets or inhaled any drugs today that were not prescribed for you? Have you injected any drugs?"

LAST ORAL INTAKE

The time of the last meal or fluid intake is important when considering potential airway problems in a patient who loses consciousness or whose condition begins to deteriorate. Determining the patient's last oral intake also may help rule out some problems such as food poisoning and food allergies. For example, symptoms of certain types of food poisoning do not usually appear for several hours. In contrast, patients who are sensitive to certain foods would develop an allergic reaction immediately after eating the foods. Some of these foods are peanut oil and shellfish. Oral intake can also point to some illnesses. For example an undiagnosed or uncontrolled patient with diabetes may report excessive hunger or thirst. In the case of some older adults, they may have inadequate food intake related to inability to procure or prepare food.

NOTE

The time of the patient's last oral intake is crucial. The time can help to determine the appropriateness of surgery. Generally, if a patient has consumed any food or drink within the previous 6 to 8 hours, surgery is delayed if possible. The delay is to prevent the patient from aspirating the stomach contents. This may occur during the induction of anesthesia. However, immediate surgery may be indicated after recent oral intake. If so, a nasogastric tube is inserted to evacuate the stomach.

FAMILY HISTORY

A **family history** of illness or disease may be relevant to the chief complaint. The paramedic should establish whether a family history of heart disease, high blood pressure, cancer, tuberculosis, stroke, diabetes, kidney disease, current contagious illness, or other ailments exists. The paramedic also should note the presence or absence of hereditary diseases during the interview. Examples of these diseases include hemophilia or sickle cell anemia. Through experience, the paramedic will develop a "personal line" of questioning to further analyze a patient's particular symptoms.

LAST MENSTRUAL PERIOD

The paramedic should obtain a menstrual history when interviewing female patients between the ages of 12 and 55 years who have abdominal pain. The patient should be asked when her last period was and if it was normal for her. This questioning may prompt the patient to discuss other significant symptoms. These symptoms may include vaginal discharge, bleeding, and pregnancy history. The patient's response should determine the need to pursue additional questions regarding contraceptive use, venereal disease, urinary tract infections, and ectopic pregnancy (see Chapter 31).

LAST BOWEL MOVEMENT

The paramedic should ask a patient about his or her bowel habits to determine whether they have been normal or abnormal. A patient with abdominal pain may describe a recent history of diarrhea, constipation, or bloody bowel movements. This information will be helpful to the receiving physician to assess the patient for bowel obstruction, dehydration, or lower gastrointestinal bleeding. At this time, the paramedic also should ask the patient about any symptoms of abnormal urinary function. These symptoms may include blood in the urine, urethral discharge, pain or burning with urination, frequent urination, or the inability to void (see Chapter 30).

EVENTS BEFORE THE EMERGENCY

The paramedic should ask the patient and bystanders about events or actions that occurred before the emergency. For example, was a fainting episode preceded by exertion or straining? Did a loss of consciousness occur before or after a fall? An attempt should be made to correlate any event with the progression of an illness or injury.

GETTING MORE INFORMATION

With experience, paramedics learn to communicate with more skill. They learn to obtain a more complete picture of a patient's illness or injury. They are able to obtain more information about a symptom or complaint. Thus they are able to use clinical reasoning to evaluate associated problems and possible effects on body systems. Defining the attributes of a symptom may require the paramedic to ask direct questions. It may also involve obtaining a history on sensitive topics. Such topics may include alcohol or other drug use, physical abuse or violence, and sexual issues. When questioning a patient about sensitive issues, the paramedic should follow these guidelines:

1. Remember that privacy is essential with all patients, regardless of age or gender.
2. Be direct and firm and do not apologize for asking a question.
3. Avoid confrontation.
4. Be nonjudgmental.
5. Use language that is easily understood but not patronizing.
6. Encourage the patient to ask any relevant questions.
7. Document carefully and use the patient's words (noted by quotation marks) when possible.

CLINICAL REASONING

The depth and focus of the patient interview are based on the case at hand. However, the paramedic should gather as much information as possible at the scene and during transport to the hospital. Questions to the patient should be selected based on the patient's chief complaint and present problem. The paramedic uses the answers to think about associated problems and body system changes related to the patient's complaint. This is known as **clinical reasoning.**

Clinical reasoning requires integrating the patient's history with the physical assessment findings. It also requires knowledge of anatomy, physiology, and pathophysiology to direct appropriate questions to the patient. The answers to the questions are analyzed by the paramedic as they are received. As such, the paramedic must be prepared to change the direction of questioning based on careful evaluation of the answers.

The Process of Clinical Reasoning

Clinical reasoning should begin with the broad possibility of systems that could contribute to the patient's complaint. In addition, it requires the paramedic to consider the patient's current symptoms, past medical history, and abnormal symptoms and physical findings. These findings are then analyzed by anatomical location. This must consider all systems found in that location that may cause or contribute to the patient's problem. The findings are then interpreted in terms of a pathological process (Table 18-1).

During clinical reasoning, the possible body systems involved must be narrowed down or ruled out. Doing so allows the paramedic to develop a working hypothesis of the nature of the problem. This is known as differential diagnosis: the process of weighing the probability of one disease versus that of other diseases possibly accounting for a patient's illness. The differential diagnosis is then tested with questions and assessments relating to systems with similar types of signs and symptoms. Finally, the competing possibilities are considered and the paramedic selects the most likely problem to treat. Careful attention must be

NOTE

Before completing the patient history, the paramedic should ask every patient these three questions:

1. Is there anything else you would like to tell me that I haven't asked you about?
2. Is there anything you are worried about that we have not discussed?
3. Do you have any questions for me?

TABLE 18-1 Assessment by Body Systems

General symptoms	Fever, chills, malaise, fatigue, night sweats, weight changes
Skin, hair, and nails	Rashes, itching, swelling
Musculoskeletal	Joint pain, loss of motion, swelling, redness, warmth, deformity
Head and neck	
General	Headache, loss of consciousness
Eyes	Visual acuity, blurring, diplopia, photophobia, pain, vision changes, flashing
Ears	Hearing loss, pain, discharge, tinnitus, vertigo
Nose	Sense of smell, rhinorrhea, obstruction, epistaxis, postnasal discharge, sinus pain
Throat and mouth	Sore throat, bleeding, pain, dental issues, ulcers, changes in taste
Endocrine system	Thyroid enlargement, temperature intolerance, skin changes, swelling of hands and feet, weight changes, polyuria, polydipsia, polyphagia, changes in body and facial hair
Male	Erectile dysfunction, penile discharge, testicular pain
Female	Menstrual regularity, last menstrual period, dysmenorrhea, vaginal discharge, bleeding, pregnancy, contraception use
Chest and lungs	Dyspnea, cough (productivity/description), wheezing, hemoptysis, TB* status
Heart and blood vessels	Chest pain (onset, duration, quality, provocation, palliation), palpations, orthopnea, edema, past cardiac evaluation and tests
Hematologic system	Anemia, bruising, fatigue
Lymph system	Enlarged or tender lymph nodes
Gastrointestinal system	Appetite, digestion, food allergies or intolerance, heartburn, nausea, vomiting (frequency, color, texture, contents), diarrhea, hematemesis, bowel regularity, stool changes (frequency, color, texture, odor), flatulence, jaundice, past GI evaluation and tests
Genitourinary system	Dysuria, pain (flank, suprapubic), frequency, urgency, nocturia, hematuria, polyuria, STDs
Neurologic system	Seizures, syncope, loss of sensation, weakness, paralysis, loss of coordination or memory, twitches, tremors
Psychiatric	Depression, mood changes, difficulty concentrating, anxiety, suicidal or homicidal ideation, irritability, sleep disturbances, fatigue on waking

**GI,* Gastrointestinal; *STD,* sexually transmitted disease; *TB,* tuberculosis.

paid to the signs and symptoms that do not fit with the working diagnosis (Figure 18-2).

SPECIAL CHALLENGES

History taking often presents special challenges. Each patient is unique. Thus each patient encounter is slightly different from all others. The paramedic must be able to adapt quickly to the special requirements of each encounter. That way the paramedic can obtain the needed information quickly. Some challenges that commonly affect history taking follow.

Silence

Silence is often uncomfortable and has many meanings and uses. For example, patients may use silence to collect thoughts, recall details, or decide whether they trust the paramedic. Silence also can defuse an emotionally tense event effectively. The paramedic should stay alert for nonverbal clues of distress or anxiety. These clues may include a worried expression or loss of eye contact, which often precede a silent period during the patient encounter. As a rule, when patients are ready to talk again, they will express feelings more clearly. A patient's silence also may result from a paramedic's lack of sensitivity, understanding, or compassion. An appropriate and caring "bedside manner" is key to good patient care.

Overly Talkative Patients

Interviewing talkative patients can be frustrating when there is limited time to obtain a health history. Although there are no perfect solutions in these situations, the following techniques may be helpful:

- Accept a less comprehensive history.
- Let the patient speak freely for the first several minutes.
- Ask questions that invite brief "yes" or "no" answers when appropriate.
- Summarize the patient's comments frequently.
- Refocus the discussion as needed.

Patients With Multiple Symptoms

Some patients (especially older patients) have a longer medical history because of age, chronic illness, and medication use. In addition, many older patients are likely to suffer from more than one illness. The paramedic should expect a longer interview and should use the techniques presented in Chapter 17. These techniques will help patients with multiple symptoms focus on the most relevant aspects of the chief complaint.

LOOK AGAIN

See Chapter 17: Therapeutic Communications, pp. 487-488.

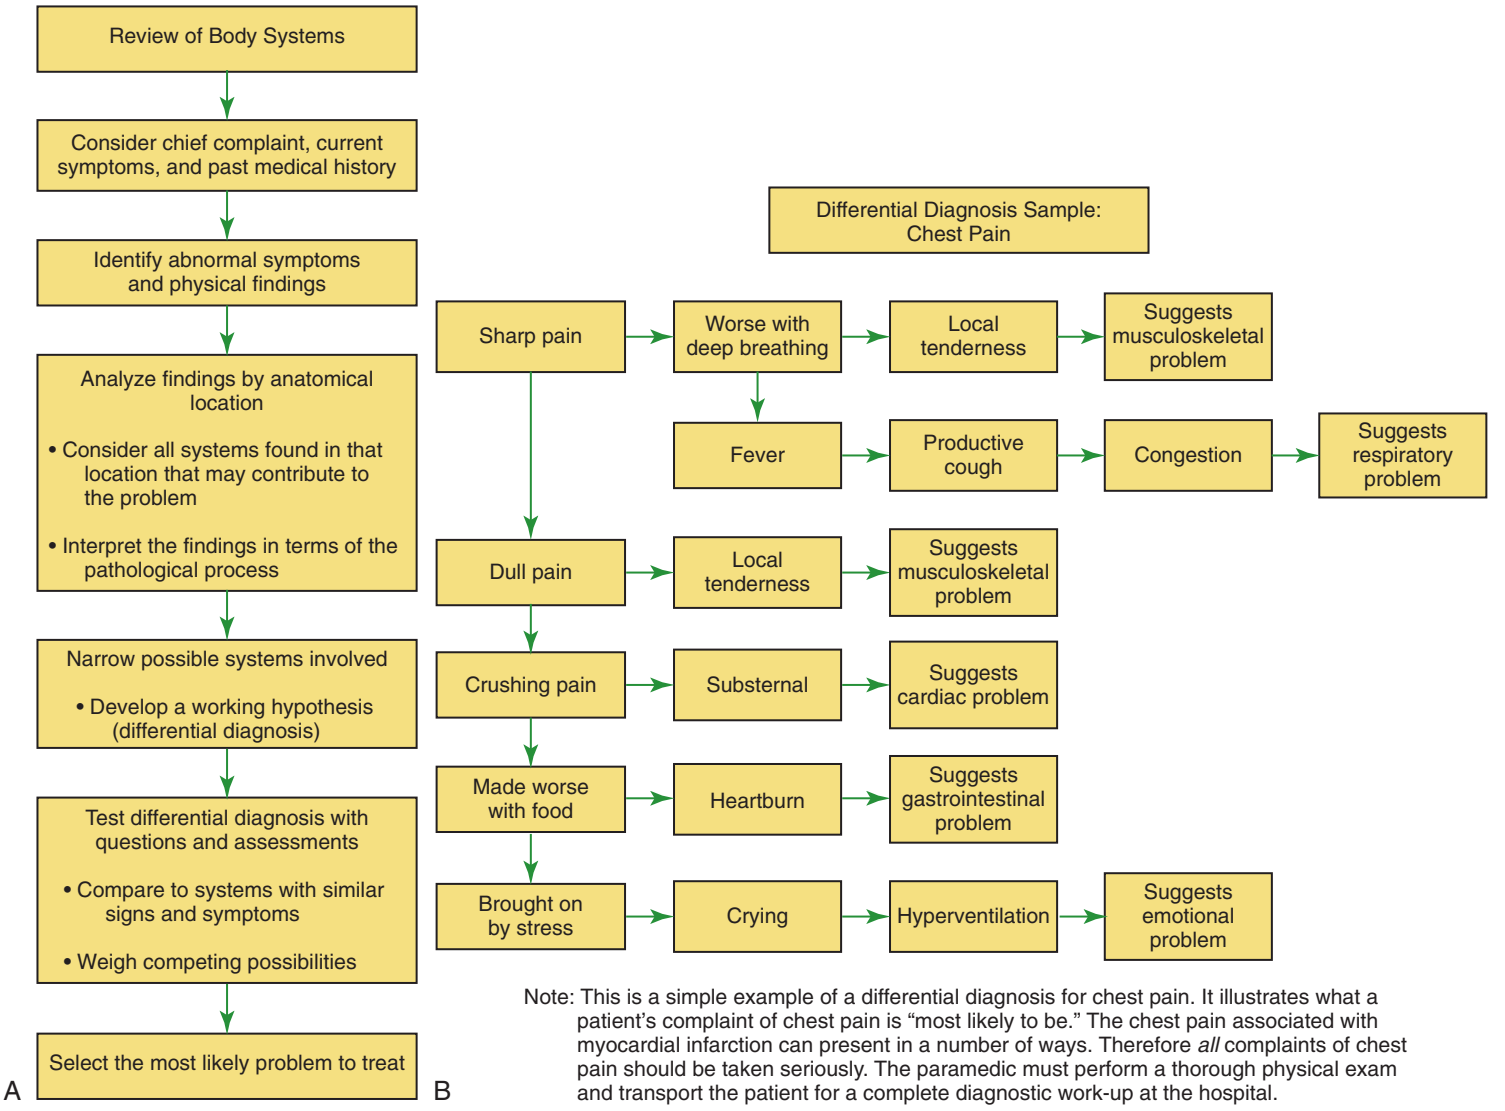

FIGURE 18-2 **A,** Review of body systems. **B,** Differential diagnosis sample—chest pain.

CRITICAL THINKING

Often patients give you a list of multiple problems. You have to identify the chief complaint. What single question would you ask?

Anxious Patients

It is normal for the patient, family, and bystanders to be anxious in an emergency situation. The paramedic must be sensitive to the nonverbal clues of anxiety and be supportive in a calm and confident way. The professional and caring attitude of the paramedic often helps to reduce the patient's anxiety. The paramedic should be aware that the anxiety may not be related directly to the illness or injury. For example, an older patient on a fixed income may worry about the cost of a hospital stay. A victim of a car crash may worry about liability and losing car insurance.

False Reassurance

The paramedic may be tempted to provide false reassurance in certain cases. Examples of this are saying "it's all right" or "everything's going to be okay." Although these false reassurances may comfort an ill or injured patient, they should be avoided until they can be given with confidence. False reassurance or over-reassurance may block open dialogue between the paramedic and the patient. The paramedic should reassure the patient that the patient's medical condition is understood and that good patient care is available. Patients also will be comforted to know that the outcome is hopeful (if appropriate) and that they will be treated with dignity and respect during their care. These verbal reassurances generally work well in most patient care situations.

Anger and Hostility

Anger and hostility are not very different from anxious behavior. They are similar in that they are natural responses in some emergency situations. The paramedic should expect these reactions at times to be displaced toward the EMS crew. The paramedic must always ensure personal and scene safety. However, anger and hostility toward the patient is never appropriate. A much more effective approach includes maintaining a calm, confident manner and setting limits on acceptable behavior.

Intoxication

Patients who are intoxicated with alcohol or other drugs should be managed with caution. Their behavior may be difficult to predict. Intoxicated patients should not be challenged or aggravated. Similar to managing patients who are angry or hostile, scene safety must be ensured and limits of acceptable behavior must be set. To ensure scene safety, the paramedic should call for assistance from law enforcement personnel when needed.

Crying

Crying can reduce tension and may help reestablish the patient's emotional stability during an emergency. If crying is excessive or uncontrollable, the paramedic should be patient. Compassion should be shown using direct eye contact to help control the crying. Reducing exhaustive crying conserves energy and promotes comfort.

Depression

Communicating with a depressed patient can be difficult. The types and causes of depression are many (see Chapter 35). The depression seen in an emergency often is due to moderate to high anxiety. Depression also may be enhanced by alcohol or substance use. The paramedic should use the communication techniques described previously for anxious patients. If possible, the paramedic should identify the seriousness of the patient's state. A physician's evaluation is encouraged.

Sexually Attractive or Seductive Patients

Paramedics and patients may be sexually attracted to each other. The paramedic should accept these feelings as normal. However, the feelings should not affect the paramedic's behavior. If a patient becomes seductive or makes sexual advances, the paramedic should firmly set limits of what is acceptable. It should be made clear that the relationship is a professional one. As discussed in Chapter 17, providing same-gender care often is the best practice. If this is not possible, an extra caregiver (or a chaperone) should stay with the patient.

Confusing Behavior or Histories

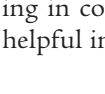
Emergency situations are often intense. In these situations, emotions can run high. Thus the paramedic should expect to find confusing histories and inappropriate or abnormal behavior. Factors that may contribute to these situations include mental illness, delirium, dementia, drug use, illness, and injury. Identifying a pattern of patient behavior may be difficult. Still the paramedic should try to identify one (e.g., signs and symptoms consistent with a certain disorder). In addition, the paramedic should attempt to lead the patient in an appropriate line of questioning.

Developmental Disabilities

The paramedic should not overlook the aptitude of patients with intellectual disabilities to provide adequate information. Patients with developmental disabilities should be interviewed just like other patients, using easily understood words and phrases. An obvious omission in the patient's answers reveals the need for more questioning. Questions may need to be stated more clearly. If the patient has severe mental retardation, the paramedic should try to obtain information from family or friends (see Chapter 51).

Communication Barriers

As discussed in Chapter 17, barriers to communication may result from social or cultural differences. These barriers also may occur because of sight, speech, or hearing impairments. The paramedic should seek assistance if possible. Family members, translators, and those with special training in communicating with the blind or the deaf may be helpful in these situations.



LOOK AGAIN

See Chapter 17: Therapeutic Communications, pp. 487-489.

Talking With Family and Friends

Friends and family are often at the scene of an emergency. Therefore the paramedic should consider them a good source of information. This is especially the case when the patient cannot provide all of the necessary information because of illness or injury. Sometimes family or friends are unavailable and more patient information is needed. In these cases, the paramedic should try to locate a third party (e.g., a neighbor) who can help supply the missing details.

SUMMARY

- Obtaining a patient history offers structure to the patient assessment. The history often identifies life threats and sets priorities in patient care.
- Content of the patient history includes date and time, identifying data, source of referral, history, reliability, chief complaint, present illness, past medical history, current health status, and review of body systems.
- The paramedic should ensure patient comfort. Several methods are available to accomplish this. The paramedic should avoid entering the patient's personal space. Sensitivity to the patient's feelings and watching for signs of uneasiness also are important. The paramedic should use appropriate language and ask open-ended and direct questions. The paramedic should use therapeutic communication techniques as well.
- Clinical reasoning requires integrating the patient's history with the physical assessment findings. It also requires knowledge of anatomy, physiology, and pathophysiology to direct appropriate questions to the patient.
- Differential diagnosis is the process of weighing the probability of one disease versus other diseases as accounting for a patient's illness.
- Many challenges can affect history taking. One of these challenges is silent or talkative patients. Another is patients with multiple symptoms. Then there are anxious, angry, or hostile patients. The paramedic also may see intoxication, crying, depression, and sexually attractive or seductive patients. False reassurance is a major issue to consider. Patients may present confusing behaviors and histories. Two other issues are developmental disabilities and communication barriers. In these last two cases, the issue of talking with family and friends can be complex as well.

CHAPTER

19 Primary Assessment

OBJECTIVES

Upon completion of this chapter, the paramedic student will be able to:

1. Identify the components of the scene size-up.
2. Identify the priorities in each component of patient assessment.
3. Outline the critical steps in primary patient assessment.
4. Describe findings in the primary assessment that may indicate a life-threatening condition.
5. Discuss interventions for life-threatening conditions that are identified in the primary assessment.
6. Distinguish priorities in the care of the medical versus trauma patient.

KEY TERMS

general impression An immediate assessment of the environment and the patient's chief complaint used to determine whether the patient is ill or injured and the nature of the illness or the mechanism of injury.

primary survey A component of the patient assessment to recognize and manage all immediate life-threatening conditions.

priority patients Patients who need immediate care and transport.

The prehospital setting usually lacks emergency physicians on the scene and diagnostic services. Because of this, priorities of care must be set based on patient assessment. These priorities include scene safety, recognition and management of life-threatening conditions, and identification of patients who require rapid stabilization and transport for definitive care. This chapter provides an overview of patient assessment with an emphasis on the primary survey. More in-depth assessment strategies are presented in Chapter 20: Secondary Assessment and throughout this text by subject matter.

SCENE SIZE-UP AND PERSONAL SAFETY

Scene size-up and personal safety are the first steps taken during every EMS response. These steps ensure scene safety for the paramedic crew, patient(s), and bystanders. The assessment of the scene and surroundings offers key information to the paramedic. As described in Chapter 16: Scene Size-Up, the priorities in scene size-up include the following:

- Determine the nature of the incident.
- Determine the maximum potential number of persons already ill or injured and needing care.
- Assess for hazards at the scene.

- Initiate a mass casualty plan if indicated (see Chapter 54).
- Notify the dispatch center to request more resources (e.g., law enforcement, fire, rescue, utility companies) and to alert area hospitals (as needed).
- Determine the best access routes and staging areas for responders.
- Secure the area as rapidly as possible, clearing unneeded persons from the scene.
- Begin triage (if needed).

Even scenes that seem safe may be dangerous. Paramedics should never enter a potentially unsafe scene until they know it is safe to approach the patient. Examples of unsafe scenes include crash-and-rescue scenes, areas with toxic substances and low oxygen, crime scenes where violence is likely, and scenes that have unstable surfaces (e.g., slope, ice, or water). Personal safety is the paramedic's first priority.

CRITICAL THINKING

Do you know a paramedic who has been injured on a scene? What caused the injury? Could the injury have been prevented?

Protective Clothing

The National Fire Protection Association[1] and Occupational Safety and Health Administration[2,3] standards for protective clothing and personal protective equipment have been adopted by many emergency response agencies. At a minimum, paramedics should have access to the following personal protective equipment, although not all will be required on every call (Figure 19-1):

- Impact-resistant protective helmet with ear protection and chinstrap
- Safety goggles with vents to prevent fogging
- Lightweight, puncture-resistant turnout coat
- Slip-resistant waterproof gloves
- Boots with steel insoles and steel toe protection

FIGURE 19-1 Personal protective equipment.

Personal Protection From Blood-Borne Pathogens

As described in Chapter 14, The Occupational Safety and Health Act of 1991 adopted the recommendations established by the Centers for Disease Control and Prevention for personal protection from blood-borne pathogens. These universal precautions have been adopted by most states and public service entities. Now universal precautions are the minimum standard of practice recommended by the Occupational Safety and Health Administration (OSHA 29 CFR Part 1910.120). These precautions are intended to be used in the case of *all* patients in which there is a risk of exposure to blood or body fluids. They also are intended to be used when the infection status of the patient is unknown. The paramedic should wash his or her hands before and after patient contact to reduce the risk of communicable disease infection. In addition, items of personal protection from blood-borne pathogens should include disposable gloves and masks, eye protection, and gowns when necessary. Table 19-1 summarizes the patient care activities and the recommended level of protection for these activities.

LOOK AGAIN

See Chapter 14: Venous Access and Medication Administration, pp. 380-381.

PATIENT ASSESSMENT PRIORITIES

After ensuring scene safety and that needed resources are available or have been requested (Figure 19-2), patient assessment can begin (Figure 19-3). Patient assessment involves the following priorities[4]:

1. Primary survey/primary assessment
2. Integration of treatment/procedures to preserve life
3. Evaluation of the priority of patient care and transport

FIGURE 19-2 Many resources may be needed at an emergency scene. (Courtesy O'Fallon Fire Protection District, O'Fallon, Mo.)

TABLE 19-1 Examples of Recommended Personal Protective Equipment for Worker Protection Against HIV and HBV Transmission* in Prehospital† Settings

Task or Activity	Gloves	Gown	Protective Mask‡	Eyewear
Bleeding control with spurting blood	Yes	Yes	Yes	Yes
Bleeding control with minimal bleeding	Yes	No	No	No
Emergency childbirth	Yes	Yes	Yes, if splashing is likely	Yes, if splashing is likely
Blood drawing	Yes	No	No	No
Starting an intravenous line	Yes	No	No	No
Endotracheal intubation, esophageal obturator use	Yes	No	No, unless splashing is likely	No, unless splashing is likely
Oral/nasal suctioning, manually cleaning airway	Yes§	No	No, unless splashing is likely	No, unless splashing is likely
Handling and cleaning of instruments	Yes	No, unless soiling is likely	No	No, unless microbial contamination is likely
Measuring blood pressure	No	No	No	No
Measuring temperature	No	No	No	No
Giving an injection	No	No	No	No

HBV, Hepatitis B virus; *HIV,* human immunodeficiency virus.
*The examples provided in this table are based on application of universal precautions. Universal precautions are intended to supplement rather than replace recommendations for routine infection control, such as hand washing and using gloves to prevent gross microbial contamination of hands (e.g., contact with urine or feces).
†Defined as setting where delivery of emergency health care takes place away from a hospital or other health care facility.
‡Refers to protective masks to prevent exposure of mucous membranes to blood or other potentially contaminated body fluids.
§Although not clearly necessary to prevent HIV or HBV transmission unless blood is present, gloves are recommended to prevent transmission of other agents (e.g., herpes simplex virus).

Primary Survey/Primary Assessment

A **primary survey** is performed on all patients to establish priorities of care. The purpose of the primary survey is to recognize and manage all immediately life-threatening conditions. This assessment establishes priorities of care, which may include **resuscitation** (Box 19-1). The primary survey consists of the paramedic's general impression of the patient. This general impression is initially based on the patient's age and appropriate appearance.

General Impression of the Patient

The **general impression** is the paramedic's immediate assessment of the setting and the patient's chief complaint. The paramedic uses the general impression to determine whether the patient:

- Appears stable
- Appears stable, but potentially unstable
- Appears unstable

The general impression of a patient is formed based on both the patient and the environment in which you find the patient. It involves a visual assessment of the patient as he or she is approached (before being close enough to begin a physical assessment). As the scene is entered, the general setting should be observed for any clues of illness, injury, or mechanism of injury. Factors that help the paramedic form a general impression are based on:

- *Position.* Is the patient upright? Prone? Contorted in an unusual position? Tripod position?

BOX 19-1 Resuscitation

Resuscitation may be called for during the initial assessment. The paramedic begins resuscitative measures such as airway maintenance, ventilatory assistance, and cardiopulmonary resuscitation immediately as needed after recognizing a life-threatening condition. Several emergency care procedures generally are required in situations involving seriously ill or injured patients. Nearly all medical and trauma patients need some form of supplemental oxygen. Other resuscitation procedures for medical and trauma patients are as follows:

Resuscitation Procedures for Medical Patients

- Oxygen and airway control
- Insertion of an intravenous line to administer drugs or volume-expanding fluid
- Administration of resuscitation medications
- Administration of electrical therapy (e.g., defibrillation, cardioversion, external pacing)

Resuscitation Procedures for Trauma Patients

- Oxygen and airway control
- Cervical spine immobilization
- Insertion of intravenous lines for volume-expanding fluid
- Administration of resuscitation medications
- Application of a pneumatic antishock garment if appropriate

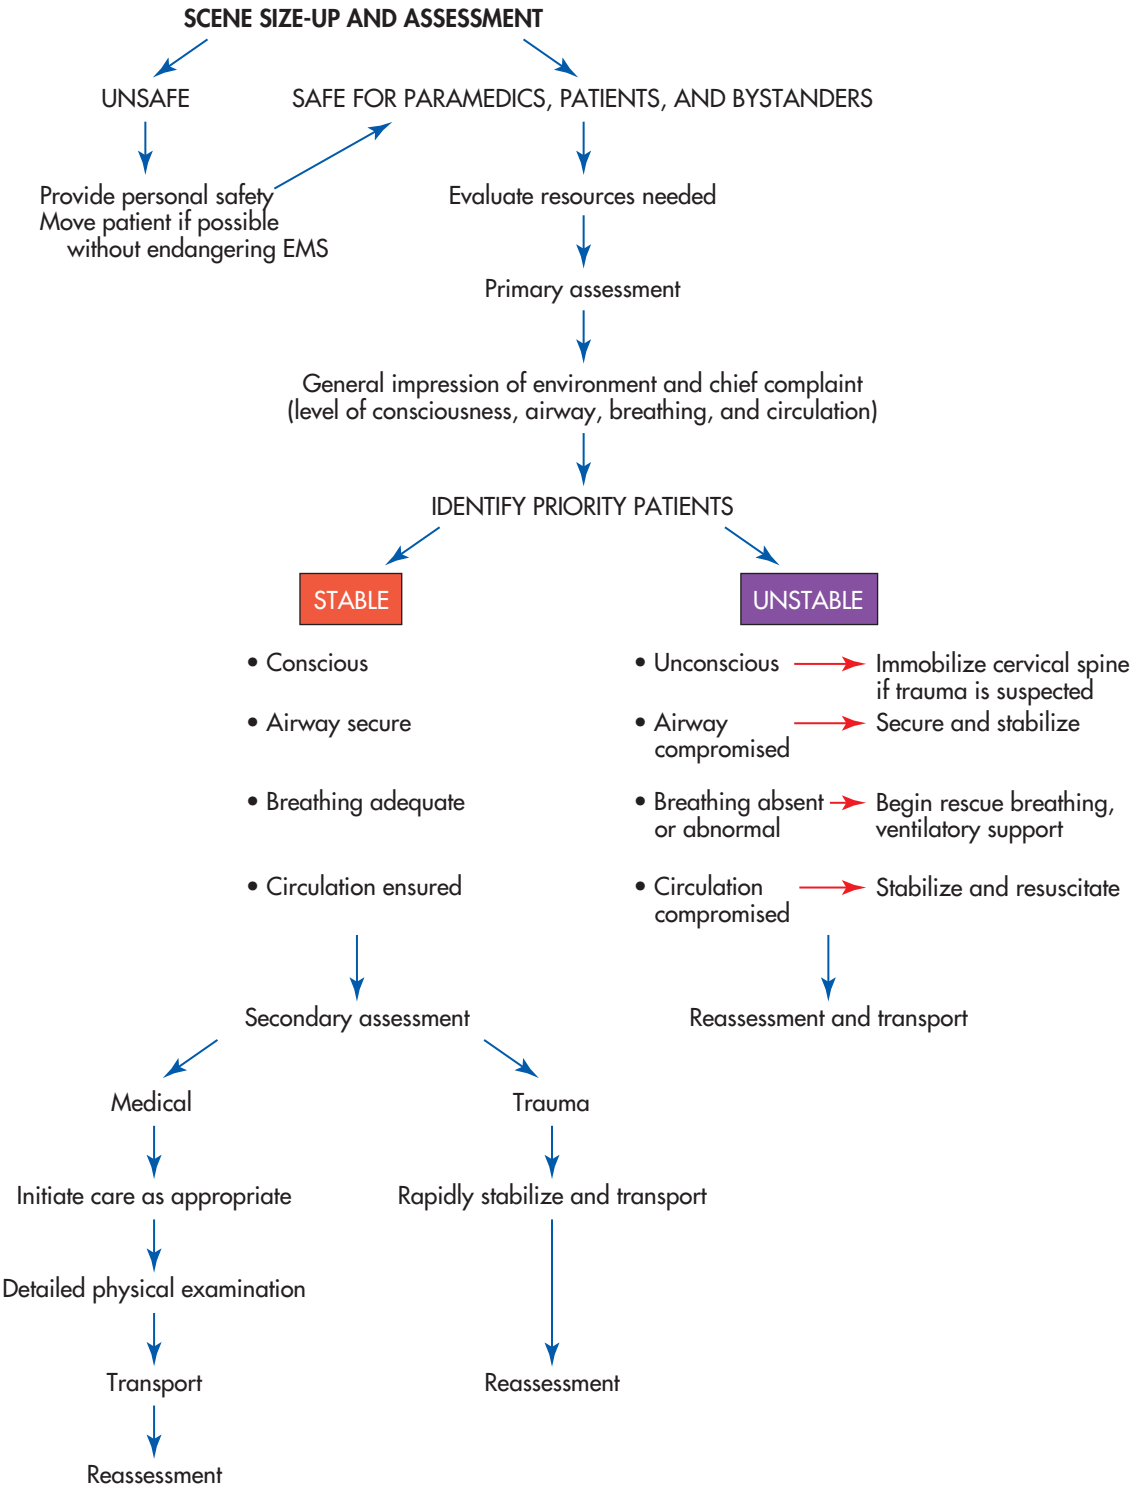

FIGURE 19-3 Components of patient assessment.

- *Work of breathing.* Is the patient breathing quietly or struggling to breathe?
- *Apparent attentiveness.* Are the patient's eyes closed or open? Does the patient turn to look at you as you enter? Is he or she staring blankly?
- *Skin color.* Is the patient pale, pink, or cyanotic?
- *Any obvious wounds noted.* Is there any bleeding or gross deformity evident?
- *Any body fluids noted.* Is there any visible blood, vomit, urine, or feces?

Patients who *appear stable* usually require only minimal care at the scene. These patients do not have life-threatening illness or injury. They are conscious and alert and their vital signs are within normal limits. Some stable patients will not require transport for physician evaluation.

Patients who *appear stable, but potentially unstable,* are injured or have underlying illness or disease. These patients may be conscious and alert and their vital signs may or may not be within normal limits. Their history of an injury or an underlying illness or disease alerts the paramedic that a decline in their status may occur. These patients are potentially unstable and always require transport for physician evaluation.

Patients who appear *unstable* have obvious signs of serious injury, illness, or disease. Their injury or illness is life threatening. These patients require immediate care and transportation to a medical facility. Initial on-scene care may include **resuscitation.**

Assessment for Life-Threatening Conditions

To assess for life-threatening conditions, the paramedic should conduct a systematic evaluation of the patient's level of consciousness, airway, breathing, and circulation.

LEVEL OF CONSCIOUSNESS

A first priority with any patient is to assess the level of consciousness. This assessment usually can be accomplished with a warm exchange with the patient. An example of such is "Hi. My name is _____. I'm a paramedic. How can I help you?" If the patient does not respond to verbal stimuli, the paramedic should assess if the patient responds to painful stimuli. This should begin with gentle tactile stimulation (e.g., rubbing the patient's shoulder), along with questions such as "Are you okay?" and "Can you hear me?" If there is no response, uncomfortable stimuli should be used to elicit a response. An example of an uncomfortable stimulus is rubbing the patient's sternum (*sternal rub*). A patient who does not respond to verbal or painful stimuli is considered unresponsive. As described in Chapter 15, the airway of any unconscious patient or any patient without a gag reflex or cough reflex must be secured immediately.

Figure 19-4 Paramedic opening an airway with head-tilt/chin-lift maneuver.

CRITICAL THINKING

What does a patient's level of consciousness tell you about the patient's oxygenation and circulation?

SHOW ME THE EVIDENCE

Researchers at an 896-bed hospital evaluated assessment of level of consciousness using the Glasgow Coma Scale (GCS) and the AVPU (*a*wake, responds to *v*erbal stimulation, responds to *p*ainful stimulation, *u*nresponsive) responsiveness scale in intentional and accidental poisoning patients who arrived to their hospital over a 6-month period in 2003. Their goal was to evaluate whether the scores could be linked to each other. A total of 1384 patients met their inclusion criteria. Although there was overlap in the scores, their data suggested the following: alert (median GCS 15); responsive to painful stimulation (median GCS 13); responsive to painful stimulation (median GCS 8); and unresponsive (median GCS 3). In general, there was difficulty using both scales in alcohol-intoxicated patients.

From Kelly C, Upex AD, Bateman D: Comparison of consciousness level assessment in the poisoned patient using the alert/verbal/painful/unresponsive scale and the Glasgow Coma Scale, *Ann Emerg Med* 44(2):108-113, 2004.

AIRWAY STATUS

The paramedic should assess the airway of any patient to ensure it is patent with good air exchange. If the patient is unresponsive, the airway should be opened and cleared of any obstructions (described in Chapter 15).

A responsive patient should be assessed for the ability to speak, noting signs of airway obstruction or respiratory insufficiency. These signs could include stridor, snoring, or gurgling. Any condition that compromises the delivery of oxygen to body tissues is potentially life threatening and must be managed immediately. Factors that may compromise the airway include the following:

- Tongue obstructing the airway in an unconscious patient
- Loose teeth or foreign objects in the patient's airway
- Epiglottitis
- Upper airway obstruction from any cause
- Facial and oral bleeding
- Vomitus
- Soft tissue trauma to the patient's face and neck
- Facial fractures

A compromised airway must be secured manually (e.g., using a modified jaw-thrust or chin-lift maneuver), or with adjunct equipment (e.g., oral or nasal airways, suction apparatus, or an advanced airway device; described in Chapter 15) (Figure 19-4). When performing an airway procedure for patients who may have a cervical spine injury, the paramedic must keep manipulation of the cervical spine to a minimum and stabilize the head and neck in a neutral position. All patients must have an airway established and maintained during the primary survey.

NOTE

The American Heart Association now recommends that patients who are in obvious cardiac arrest should be treated first with chest compressions. This is then followed by an assessment of airway and breathing (C-A-B).[7] See Chapter 22.

CRITICAL THINKING

Securing a patent airway should always receive priority over spinal immobilization. However, both are crucial tasks in the primary survey.

The patient whose airway is obstructed by a foreign object should be managed using the guidelines currently recommended by the American Heart Association and the American Red Cross. If these maneuvers fail, medical direction may recommend direct laryngoscopy or cricothyrotomy (see Chapter 15).

BREATHING STATUS

The breathing of a responsive patient can be assessed as (1) adequate rate and quality; (2) too fast (greater than 24 breaths/min); too slow (less than 8 breaths/min); or absent (e.g., choking from airway obstruction). The breathing of an unresponsive patient can be assessed as (1) adequate rate and quality; (2) inadequate; or (3) absent.

Breathing can be assessed by evaluating the rate, depth (tidal volume), and symmetry of chest movement. The patient's chest wall should be exposed and palpated for structural integrity, tenderness, and crepitus. Use of muscles of respiration (accessory muscles) in the neck, chest, and abdomen should be observed and noted. The paramedic should auscultate the lungs for the presence of bilateral breath sounds and should listen to the patient's speech. A patient who has difficulty speaking without pain or who cannot talk without gasping for air may need ventilatory support. Respiratory abnormalities discovered during the primary survey that may indicate a potentially life-threatening condition include the following:

- Cyanosis
- Respiratory distress with dyspnea or hypoxia
- Asymmetrical chest wall movement
- Chest injury (e.g., tension pneumothorax, flail segment, open chest wound)
- Tracheal deviation
- Distended neck veins

Ill or injured patients with ineffective respirations need oxygen and ventilatory support. These patients require supplemental high-concentration oxygen. If the respiratory rate of a critically ill or injured patient is less than 8 or more than 24 respirations per minute, ventilatory assistance may be needed.[4] The paramedic may coordinate assisted ventilation with the patient's respiratory efforts. Or the paramedic may intersperse assisted ventilation between the patient's own respiratory efforts as needed to maintain adequate oxygenation.

CRITICAL THINKING

Some patients with respirations between 8 and 24 breaths/min may require assisted ventilation. Can you think of any such situations?

If respirations are absent, the paramedic should initiate rescue breathing with a pocket mask. Positive-pressure ventilation, which can be provided via a bag-valve device with supplemental oxygen, should follow. Endotracheal intubation or other advanced airway devices may be indicated. The paramedic also should consider spinal precautions and barrier protection with all airway procedures (see Chapter 15).

CIRCULATORY STATUS

The patient's circulatory status should be evaluated after assessing airway and breathing. For trauma patients, this assessment includes a quick head-to-toe survey to identify and control severe bleeding. The paramedic should assess the patient's skin color, moisture, and temperature quickly. The pulse should be evaluated for quality, rate, and regularity.

Pulse. A quick evaluation of the patient's radial or carotid pulse may reveal any of the following: a normal rate of 60 to 100 beats/min, tachycardia (a fast rate, greater than 100 beats/min), bradycardia (a slow rate, less than 60 beats/min), an absent rate (asystole), or an irregular heart rate. The site of an obtainable pulse also may offer critical details about a patient's systolic blood pressure and tissue perfusion.[5] For example, if a radial pulse is not palpable in an uninjured extremity, the patient may be in a decompensated state of shock (hypoperfusion). A patient will lack a palpable femoral or carotid pulse when in cardiac arrest.

Capillary Refill Time. The capillary filling time may offer crucial details about the patient's cardiovascular status. The capillary refill test is thought to be most reliable in children younger than 12 years of age. The paramedic performs this test by blanching the patient's nail bed or the fleshy eminence at the base of the thumb, and then measuring the time it takes for normal color to return. A filling time of more than 2 seconds is caused by shunting and capillary closure to peripheral capillary beds. This indicates inadequate circulation and impaired cardiovascular function. Factors such as the patient's age, gender, and environment may affect the filling time. Thus the paramedic should use this test only as a possible indicator of circulatory and perfusion status.[6] Other signs and symptoms of inadequate circulation and impaired cardiovascular function include the following:

- Altered or decreased level of consciousness
- Distended neck veins
- Increased respiratory rate
- Pale, cool, diaphoretic skin
- Distant heart sounds
- Restlessness
- Thirst

CRITICAL THINKING
How do age, gender, and the environment affect capillary refill time?

NOTE
When an unconscious patient lacks a palpable femoral or carotid pulse, chest compressions should be initiated and cardiac arrest protocols should be followed[7] (see Chapter 22). In cases of severe external hemorrhage, bleeding should be controlled using direct pressure and elevation. If arterial bleeding is not controlled with direct pressure, a tourniquet should be applied (see Chapter 38). In most cases, these procedures to control bleeding also are effective during transport. Regardless of the cause, all patients with circulatory compromise need rapid stabilization. This may include intravenous administration of fluids and medications and rapid transportation to an appropriate medical facility.

Disability—Brief Neurological Evaluation

If time permits, a brief neurological (neuro) evaluation should be performed on all patients during the primary survey. The brief neuro exam includes level of consciousness, pupil size and reactivity, speech, and motor function. The purpose of this brief neuro exam is to gather information about any level of altered consciousness. (The neurological examination will be described in detail in Chapter 20.)

- *Level of consciousness:* The initial assessment of level of consciousness performed early in the primary survey classifies a patient as responsive or unresponsive. The brief neuro exam goes further by establishing that a patient is alert; is oriented to person, place, and date; and is aware of his or her surroundings. A patient who does not "pass" this test is assumed to be disoriented. Any deviations to a "normal" test should be recorded and reported to personnel at the receiving hospital. Other assessments, such as the Glasgow Coma Scale and stroke assessments, also may be indicated when evaluating the patient's level of consciousness (see Chapter 20).
- *Pupil size and reactivity.* As a rule, healthy people have pupils that are equal in size and react in concert to light. That is, both pupils should constrict at the same time when exposed to light and should dilate at the same time when exposed to darkness. Causes of unequal pupils and impaired reactivity include ocular prostheses, eye trauma, head trauma, stroke, and conditions that may impair oxygenation.
- *Speech.* A healthy person's speech should be clear and easy to understand. Slurred speech, difficulties with speech, or nonsensical speech can result from stroke, seizure, head or facial injury, medical conditions that cause speech impairment, and alcohol or other drug use.
- *Motor function.* An uninjured patient should be able to move all extremities on command and without difficulty. The patient's walk and gait should be smooth and fluid. Conditions that may affect motor function and movement include extremity injury, stroke, head injury, alcohol or other drug use, and medical conditions such as multiple sclerosis and arthritis.

NOTE
A primary purpose of the brief neuro exam is to form a baseline assessment for future evaluations. This base line can then be compared to assessments performed by hospital staff after the patient has been delivered to the emergency department. Baseline assessments help identify negative and positive trends that may occur during the course of a patient's care.

Exposure

Some trauma patients require only minimal care and do not need to have their bodies fully exposed at the scene. Examples include stable patients with minor injuries that are isolated to a specific body part. Other patients with significant injury and those patients who are potentially unstable should be completely undressed as part of the primary survey. Exposure of the body may reveal other injuries that are not easily visible when the patient is clothed. Examples include bullet wounds, stab wounds, hidden fractures, and large areas of bruising or hematoma formation. When full-body exposure is indicated, every effort should be made to ensure the patient's privacy. Ideally, a paramedic of the same gender should remove the patient's clothing, make a visual inspection, and then appropriately cover the patient for privacy and warmth.

Assessment of Vital Functions
